SUBJECT: **Parsons Final Sampling and Analysis Plan for Munitions Response and CERCLA Closure Program, Seneca Army Depot Activity; Contract FA8903-04-D-8675, Task Order 26, CDRL A006.**

Dear Mr. Wolfe and Mr. Absolom:

Parsons Infrastructure & Technology Group, Inc. (Parsons) is pleased to submit the Final Sampling and Analysis Plan for the Munitions Response and CERCLA Closure Project at the Seneca Army Depot Activity (SEDA) located in Romulus, New York.

This Sampling and Analysis Plan was prepared in accordance with the Scope of Work (SOW) for Task Order 0026 under Contract FA8903-04-D-8675 and is provided in fulfillment of requirements under CDRL A006. Once approved, it is Parsons' intention to use this document as the primary sampling and analysis document for activities performed for the Seneca Army Depot Activity.

Parsons appreciates the opportunity to provide you with this Sampling and Analysis Plan. Should you have any questions, please do not hesitate to call me at (617) 449-1405 to discuss them.

Sincerely,

Todd Heino, P.E.
Program Manager

1.0 INTRODUCTION

Parsons has prepared this Site-Wide Sampling and Analysis Plan (SAP) for Munitions Response and CERCLA Closure program at the Seneca Army Depot Activity (SEDA) in Romulus, New York. This site-wide SAP will serve as an umbrella document under which Munitions Response and CERCLA Closure activities are conducted. When necessary, activity-specific information not covered in this site-wide SAP will be added to detailed activity-specific work plans, which will use the generic SAP as an informational reference. The use of this generic SAP, with supplemental activity-specific work plans as needed, is a significant opportunity to use a graded approach, reducing repetition and streamlining the SAP development, review, and approval process.

The SAP mainly consists of two parts: Quality Assurance Program Plan (QAPP, Sections 2 through 15) and Field Sampling Plan (FSP, Section 16).

The generic QAPP prepared for the Seneca Army Depot Activity states the expectations and specifications for obtaining the type and quality of environmental data needed for the project and describes the policies and procedures for ensuring that work process, products, or services satisfy the stated expectations and specifications. The QAPP includes definitions and generic goals for data quality and minimum requirements for quality assurance/ quality control (QA/QC) samples. The FSP provides general information and standard operating procedures (SOPs) applicable to sampling and analytical activities to be performed at all sites at SEDA.

It should be noted that the SAP may include discussions on procedures or methods that are not applicable to all specific sites encompassed by the Munitions Response and CERCLA Closure activities program at the Seneca Army Depot. A Site-Specific work plan (SS-WP) will be prepared for each individual site where sampling and analytical activities are being conducted. The work plan will serve as addenda to this SAP. It is intended that once the SAP is finalized, it will not be modified (except for programmatic changes) and will serve as a programmatic document. Site-specific sampling information and any exceptions or proposed changes to the SAP will be addressed and included in the site-specific work plan. The majority of information contained in this SAP should not be repeated in the SS-WP. The methods specific to each site should specify the appropriate detection limit and reporting limit information. Any deviations from this SAP (e.g., holding times, detection limits, sampling methods, etc.) should be brought to the attention of the management team.

The SS-WP should not be a stand-alone document from this SAP. This SAP will provide the majority of the QA/QC information; the SS-WP should simply supplement this information by providing site-specific requirements. Section 17 of this SAP summarizes key elements that should be included in the SS-WP.

The Seneca Site-Wide SAP is prepared consistent with the guidance including, but not limited to, the following:

- Guidance for the Data Quality Objectives Process, United States Environmental Protection Agency (USEPA) QA/G-4, 2000a
- USEPA Requirements for Quality Assurance Project Plans, USEPA QA/R-5, 2001a
- Data Quality Objectives Process for Hazardous Waste Site Investigations, USEPA QA/G-4HW, 2000c
- Uniform Federal Policy for Quality Assurance Project Plans, Evaluating, Assessing, and Documenting Environmental Data Collection and Use Programs, USEPA, 2005a
- Guidance for Quality Assurance Project Plans, USEPA QA/G-5, 2002b
- Quality Management Plan for Western Ecology Division, USEPA, 2001b
- Guidance for the Development of Quality Assurance Project Plans for Environmental Monitoring Projects, USEPA Region 2, 2004
- Analytical Service Protocols (ASP), New York State Department of Environmental Conservation (NYSDEC), 2000
- Technical Guidance for Site Investigation and Remediation SW-96-09: Development and Review of Site Analytical Plans, NYSDEC, 2001
- Draft DER-10 Technical Guidance for Site Investigation and Remediation, NYSDEC, 2002
- Chemical Quality Assurance for Hazardous, Toxic and Radioactive Waste (HTRW) Project, United States Army Corps of Engineers (USACOE) EM200-1-6, 1997
- Requirements for the Preparation of Sampling and Analysis Plan, USACOE EM200-1-3, 2001

Appendix A presents a cross reference table for selected applicable SAP guidance.

2.0 PROJECT DESCRIPTION

2.1 SENECA ARMY DEPOT PROJECT BACKGROUND

SEDA is located approximately 40 miles south of Lake Ontario and is located in the towns of Varick and Romulus, New York (Figure 1). The former Administration area of the Depot lies immediately southwest of the center of Romulus, New York (NY), 12 miles south of the village of Waterloo and town of Seneca Falls, and 2.5 miles north of the village of Ovid, NY. The two closest major cities are Rochester, NY, which is located approximately 60 miles northwest, and Syracuse, NY, which is located approximately 60 miles northeast, respectively.

SEDA is located in an uplands area, where the elevation ranges from approximately 600 feet (ft.) National Geodetic Vertical Datum (NGVD 1929) along the western boundary of the Depot to nearly 760 feet NGVD 1929 in the central portion of the Depot's eastern boundary. The uplands area where SEDA is located forms a divide separating two of the New York Finger Lakes; Cayuga Lake on the east and Seneca Lake on the west. Sparsely populated farmland covers most of the surrounding area. New York State Highways 96 and 96A border SEDA to the east and west, respectively. Figure 2 presents a plan view of SEDA.

The 10,587-acre SEDA facility was obtained by the United States Government in 1941 and was operated by the Department of the Army (DOA) until 2001. Since 2001, selected land within the former Depot has been transferred to other interested parties (e.g., State of New York, Seneca County) for beneficial reuse purposes. From its inception in 1941 until 1995, SEDA's primary mission was the receipt, storage, maintenance, and supply of military items, including munitions and equipment. Seneca Army Depot was proposed for inclusion on the National Priorities List (NPL) on July 14, 1989; the Depot's listing was finalized on August 30, 1990. Once Seneca Army Depot was listed on the NPL, the Army, USEPA, and NYSDEC identified a list enumerating 57 solid waste management units (SWMUs) where historic data or information suggested, or evidence existed to support, that hazardous materials or hazardous wastes had been handled and may have possibly been released and migrated into the environment. Each of these sites was identified in the Federal Facilities Agreement (FFA) (Army, USEPA, NYSDEC, 1993) signed by the three parties, and this list subsequently expanded to include 72 sites. Activities at the SEDA are regulated by the Comprehensive Environmental Response, Compensation, and Liability Act of (CERCLA) and Resource Conservation and Recovery Act (RCRA). USEPA and NYSDEC are the approval entities for the project. The site number is listed as NY0213820830 and 8-50-006 under the USEPA and NYSDEC program, respectively.

The Depot's mission changed in early 1995 when the Department of Defense (DoD) recommended closure of the SEDA under the Base Realignment and Closure (BRAC) process. This

recommendation was approved by Congress on September 28, 1995, and the Depot was closed by July 2001.

This project will be performed by Parsons and by subcontractors managed and administrated by Parsons under the Air Force Center for Environmental Excellence's Contract titled Munitions Response and CERCLA Closure (FA8903-04-D-8675, Task Order 0026).

2.2 PROJECT SPECIFIC BACKGROUND

Background information for each specific site within the Depot will be included in the SS-WP. The SS-WP will present information of site location, site contamination history, and findings from previous investigations.

2.3 PROJECT SCOPE AND OBJECTIVES

The primary objective of the project is to perform munitions response and CERCLA closure activities for four sites at the Seneca Army Depot Activity, which is located in Seneca County, New York. The four sites are the 3.5" Rocket Range (SEAD-46), the former EOD Range (SEAD-57), the Rumored EOD Range (SEAD-002-R-01), and the Grenade Range (SEAD-007-R-001). Specific work activities to be performed include:

- Develop project work plans and cost proposals;
- Mobilize and once work is complete, demobilize from the site;
- Removal of vegetation as needed;
- Maintain general site security;
- Perform necessary mapping to identify or reacquire anomalies that may represent Material Potentially Posing and Explosive Hazard (MPPEH);
- Perform appropriate intrusive investigation for all anomalies over 50 millivolts (mV) response;
- Excavate and clear all soil and debris in areas showing more than 600 anomalies per area;
- Sampling and analysis of excavated soils to determine soil reuse/disposal options;
- Sampling and analysis of final surface soils left at the sites to document achievement of CERCLA closure;
- Preparation and submittal of necessary draft and final project completion reports, proposed plans and records of decisions to document CERCLA closure of the sites; and,
- Complete and document necessary surveys and mapping.

Work will be conducted in accordance with the FFA (USEPA, NYSDEC, Army, 1993), CERCLA, RCRA, National Oil and the Hazardous Substances Contingency Plan (more commonly called the

National Contingency Plan, or NCP) requirements, with regulatory coordination of the NYSDEC and the USEPA Region 2.

2.4 APPLICABLE REGULATIONS/STANDARDS

Applicable or Relevant and Appropriate Requirements (ARARs) are promulgated regulatory standards or requirements and as such are legally enforceable and generally applicable and relevant to the media or conditions at the site. In addition to ARARs, CERCLA allows advisories, criteria, or guidance developed by USEPA, other federal agencies, and other state and local agencies to be evaluated as "To Be Considered" (TBC) regulatory items, which may be useful during the development of CERCLA remedies. The following ARARs and TBCs have been identified for the project.

Soils/Sediment

- NYSDEC Technical and Administrative Guidance Memorandum (TAGM) HWR-94-4046 (January 1994) – TBC.
- EPA Regional Preliminary Remediation Goals (PRGs) or Risk Based Concentrations (RBCs) – TBC.
- NYSDEC Technical Guidance for Screening Contaminated Sediments. Updated 1999 - TBC.

Groundwater/Surface Water

- Technical Operating Guidance Series (TOGS), 1.1.1, Class GA (groundwater) or Class C (surface water) Standards (June 1998 with amendments) – ARAR.
- National Primary Drinking Water Regulations – ARAR.
- Technical Operating Guidance Series (TOGS), 1.1.1, Class GA (groundwater) or Class C (surface water) Guidance Values (June 1998 with amendments). - TBC
- National Recommended Water Quality Criteria – TBC.

Potentially applicable ARARs and TBCs are provided in Table 1-A and 1-B for soils/sediment and groundwater/surface water, respectively.

3.0 PROJECT ORGANIZATION AND RESPONSIBILITIES

3.1 PROJECT ORGANIZATION

The organizations who will be directly involved in the performance of the Munitions Response and CERCLA closure project will include the Air Force Center for Environmental Excellence (AFCEE), the U.S. Army, the NYSDEC, USEPA Region 2, SEDA, Parsons, and subcontractors under contract to Parsons. The organizations, key personnel from each organization, and personnel contacts are listed in the following table. A chart showing the project organization is presented in Figure 3. Project-specific responsibilities (to include any additional subcontractors) and project-specific team will be identified and discussed in detail in the SS-WP.

Organization	Position	Name & Address	Responsibility	Phone	Fax	Email

3.2 ROLES AND RESPONSIBILITIES

3.2.1 USEPA and NYSDEC

The USEPA, Region II (Superfund Federal Facilities Section) and NYSDEC (Division of Environmental Remediation) provide project regulatory review and oversight, and are responsible for confirming and approving the completion of the site activities. These agencies will receive copies of the SAP. All applicable communication and reports will be delivered from Parsons to SEDA for delivery to NYSDEC and USEPA. NYSDEC and USEPA are responsible for the final acceptance of all documents with authority under CERCLA and RCRA.

3.2.2 Air Force Center for Environmental Excellence (AFCEE)

AFCEE is responsible for the munitions response and CERCLA closure contract administration, management and technical project oversight. The AFCEE Contracting Officer's Representative (COR) is Mr. Lonnie Wolfe. Mr. Wolfe or his designee will provide day-to-day liaison with the SEDA, the USACE NY District and Parsons to ensure that appropriate coordination and oversight is maintained throughout the performance of the project. Mr. Wolfe will also oversee and verify the performance and completion of contractual obligations.

3.2.3 SEDA

The U.S. Army's Base Realignment and Closure (BRAC) Division is responsible for the administration and management of the closure and transfer of the former Seneca Army Depot Activity in accordance with the mandates of the executive and legislative branches of the federal government. Mr. Stephen Absolom is the BRAC Office's Environmental Coordinator (BEC) and is the installation manager for SEDA. Mr. Absolom is responsible for ensuring that the Army's munitions response and CERCLA closure objectives at the SEDA are met. Mr. Absolom or his designee is responsible for programming funds; establishing and maintaining the CERCLA information repository; administrating, managing and coordinating public review and approval of the BRAC closure operations; monitoring and promoting regulator, stakeholder, client, and contractor communication and coordination; and reviewing, validating, and approving the performance and completion of necessary munitions response and CERCLA closure actions.

3.2.4 U.S. Army Corps of Engineers (USACE), NY District

USACE, NY District administers and manages contract funding and provides technical oversight support to the Army's BRAC Office at the SEDA. Mr. Randall Battaglia, Ms. Janet Fallo, Mr. Thomas Enroth, and Mr. Thomas Battaglia are project managers that oversee various projects at the

Depot in support of Mr. Absolom. Mr. Randall Battaglia coordinates project funding with AFCEE's COR.

3.2.5 Parsons Infrastructure & Technology Group Inc. (Parsons)

Parsons has been contracted by AFCEE to administer, manage, schedule, coordinate, perform, and to document completion of the munitions response and CERCLA closure actions at the five designated sites at the former Seneca Army Depot Activity. Parsons' munitions response and CERCLA closure actions must be approved by AFCEE, the Army's BRAC Division, the regulatory community and other community stakeholders. Parsons' assembled project team consists of members who have extensive experience in conducting munitions response and CERCLA site investigation and remedial actions. Key personnel and their respective roles and responsibilities are discussed below.

3.2.5.1 Project Manager

Mr. Todd Heino, P.E., is Parsons' project manager and will have overall responsibility for implementing, completing and documenting approval of the munitions response and CERCLA closure project at the SEDA. Parsons' Boston office is responsible for administrating, managing, directing and conducting the work under the contract and will be supported by other Parsons offices as needed. Mr. Heino is also responsible for directing, scheduling, overseeing, and coordinating all project activities. He will maintain liaison with the AFCEE COR, the USACE's BEC and support staff, the regulatory community, interested stakeholders and the contracted team, and he will coordinate all necessary efforts required under this contract to prepare and gain administrative approval of project completion. Mr. Heino is also responsible for overseeing the preparation and submittal of the QAPPs and necessary revisions and amendments, and gaining approval of the provided contract deliverable.

3.2.5.2 Project Team

Parsons' project team consists of technical and administrative personnel, including a quality assurance office (QAO), a project chemist, geologists, geophysicists, engineers, designers, chemists, risk assessors, health and safety personnel, field sampling personnel, qualified UXO technicians, contract and subcontract administrators, and project controls and other administrative support personnel. The project team is responsible for developing or collecting providing all the information required by the SAP and for resolving all technical issues for the project. All project personnel are responsible for implementing the SAP, and for documenting and reporting all deviation from the SAP to the project manager. Corrective action procedures must be implemented when deviations from the SAP are noted or whenever project personnel identify sampling or analytical problems that could potentially affect data quality or usability.

Technical Director and Quality Assurance Officer (QAO)

Mr. John Lanier is Parsons' Technical Director and Quality Assurance Officer (QAO) for the SEDA munitions response and CERCLA closure activities at the five identified sites. As Technical Director, Mr. Lanier or his designee will provide technical guidance and oversight for all field activities, and will conduct field audits and coordinate any corrective actions with the project manager and the project staff. As the QAO, Mr. Lanier will not be involved in the project data generation process but is responsible for reviewing the SAP and data generating process to ensure that the work is conducted in accordance with the requirements presented in the SAP and to certify that the data is collected and analyzed using the appropriate procedures. The QAO, or designated team, is responsible for preparing and revising the SAP.

Field Analyst

If field analysis is planned, a qualified field analyst will be assigned to conduct the field analysis. A field analyst must have the following minimum qualifications: (1) completion of a certification course or training by an experienced analyst who has demonstrated proficiency in the method; or, (2) demonstration of the analyst's proficiency by correlation of the analyst's results with laboratory confirmation analysis.

Field Team Leader

The field team leader is an experienced person who has demonstrated proficiency in the sampling method. The field team leader is responsible for ensuring that calibration is completed daily in accordance with this procedure, that equipment and instrument inspection and maintenance is conducted, that measurements are taken to the specified accuracy, and that the requisite QA/QC samples are submitted to the laboratory.

Field Sampling Team

Field sampling team is responsible for sampling preparation, sample collection, sample storage at field, sample packaging, sample delivery, and field measurements. The team should be familiar with the SAP.

Project Chemist

The project chemist will have at least two years experience in data review and be familiar with USEPA Region 2 organic data validation requirements and the New York ASP. The project chemist is responsible for data verification, data validation, and data usability evaluation for all analytical data generated for the project.

The project chemist will be responsible for communicating with the laboratory on a regular basis regarding sample shipment, receipt, and login, and all issues relating to data quality, scheduling and data packages. The project chemist will review all project and laboratory documentation related to the analytical process and will prepare data verification reports as needed.

Data Users

Technical personnel who use the collected data to perform their responsibilities (e.g., risk assessment, remedial design) will use the data for various purposes. Data users are responsible for communicating additional data needs to the project manager.

Project Health and Safety Officer

Parsons' Project Health and Safety Officer oversees the health and safety of personnel involved in the work. The Project Health and Safety Officer is responsible for developing the Health and Safety Plan for the project and has the authority to initiate a work stoppage due to health and safety concerns.

3.2.6 Subcontractor

Laboratory

The laboratories selected to perform analyses for samples collected at Seneca site must be certified under the Environmental Laboratory Approval Program (ELAP), implemented by the New York State Department of Health (NYSDOH), and be capable of providing complete environmental analytical services consistent with USEPA protocols and NYSDEC ASP. The laboratories should implement QA/QC procedures consistent with the NYSDEC ASP protocol, Region 2 SOPs, and this generic SAP. Prior to sample analysis, each laboratory must submit detailed information regarding the ELAP certification, laboratory project manager, and QA/QC procedures to Parsons. Parsons Quality Assurance (QA) officer or project chemist will review the ELAP certification and QA/QC manual submitted by laboratories to ensure consistency with requirements by this SAP.

All analytical data will be verified prior to being released by the Laboratory. Verification will include both editorial and technical reviews. The electronic format of the data will be reviewed along with the hardcopy data package. A final review of the data package will be performed and the approved data package signed by the project manager, or designee, when complete.

Other Subcontractors

Other subcontractors identified for specific project will be specified in the SS-WP. The following provides a list of potential subcontractors that may be used for the project.

General Contractors

Sevenson Environmental Services, Inc. (Buffalo, NY)
USA Environmental Inc. (Tampa, FL)

3.3 COMMUNICATION PATHWAYS

Communication is one of the key components to a successful project. Communication pathways and modes of communication are delineated in Table 2.

The Laboratory shall communicate with Parsons by telephone or via email as necessary throughout the process of sample scheduling, shipment, analysis and data reporting, to ensure that samples are properly processed. Communications between the laboratory and Parsons will primarily be handled by the project chemist and the quality assurance officer, but as necessary will also involve Parsons' project manager.

The laboratory's project representative/administrator shall immediately notify Parsons of: any irregularities with samples or sample paperwork received, noting discrepancies between paperwork and verbal orders placed by authorized Parsons personnel; problems encountered in sample analyses that could affect data quality or schedule; and, any laboratory conditions that may impact the timeliness of analyses or data reporting. In particular, the Laboratory shall notify Parsons in advance regarding any data that could potentially be late and shall specify an estimated delivery date.

The field team leader shall communicate with the project manager or QA officer by telephone as necessary throughout the munitions response and CERCLA closure project to ensure that samples are properly collected and delivered.

4.0 DATA QUALITY OBJECTIVES

Data Quality Objectives (DQOs) define the type, quantity, and quality of data that are needed to answer specific environmental questions and support environmental decisions. The development of DQOs for a specific site and measurement takes into account project needs, data uses and types and needs, and data collection. These factors determine whether the quality and quantity of data are adequate for its end use. DQOs are implemented so the data are legally and scientifically defensible. This section presents the general process of DQO development and factors that will affect DQO development (Sections 4.1 and 4.2). Site-specific DQOs will be defined in the SS-WP. As part of the DQO development, data performance criteria need to be determined. Section 4.3 presents indicators that will be used to represent data quality and their performance requirement criteria. Section 4.4 describes method detection limits, reporting limits and instrument calibration limits. Section 4.5 and Section 4.6 describe quality control activities and quality control checks for the project, which will be conduced to ensure the data quality.

4.1 DATA QUALITY OBJECTIVE DEVELOPMENT PROCESS

Development of data quality objectives will be conducted in accordance with the USEPA (2000a, c) Guidance for the data quality objectives process, the USEPA (2005a) Uniform Federal Policy for Quality Assurance Project Plans, and the NYSDEC (2001) Development and Review of Site Analytical Plans.

The following elements will be incorporated into the DQO development in accordance with the NYSDEC guidance and the sections corresponding to the elements are specified:

- definition of data types and data uses (Section 4.2),
- specification of data performance criteria (Section 4.3),
- discussion of implementation mechanisms of sampling for routine, baseline and expanded parameters (Sections 4.4 and 4.5)
- presentation of action levels or applicable standards (Section 2.4)

A Systematic Planning Process (SPP) described in the USEPA (2005a) guidance or the Data Quality Objectives Process (DQOP) discussed in the USEPA (2000a, c) guidance will be used to identify site-specific DQOs based on the specific site information.

The SPP process, presented in Figure 13 of the USEPA (2005a) guidance, is based on the scientific method and includes concepts such as objectivity of approach and acceptability of results. It uses a common sense graded approach to ensure that the level of detail in planning is commensurate with the importance and intended purpose of the work and the use of available resources. This framework

promotes communication between all organizations and individuals involved in an environmental project.

When critical environmental decisions need to be made (e.g., final decision-making or compliance with a standard), the USEPA (2000a) defined DQOP will be followed. The DQOP requires statistical expertise to define the amount of error acceptable when making an environmental decision and includes the following seven steps:

- Step 1: State the problem
- Step 2: Identify the decision
- Step 3: Identify the inputs to the decision
- Step 4: Define the boundaries of the study
- Step 5: Develop a decision rule
- Step 6: Specify tolerable limits on decision errors
- Step 7: Optimize the design for obtaining data

The DQO process is iterative, i.e., the seven-step process should be repeated, as needed, based on newly acquired data and/or information.

DQO for a specific project will be presented in a SS-WP. In general, the DQO will be developed using the SPP or DQOP for the Data Quality Objectives Process. Most projects under the contract will be judgmental-based and therefore SPP, a less iterative process, is normally used to develop the project's data quality criteria.

4.2 DATA TYPES AND DATA USES

DQOs are based on the premise that different data types or different data uses require different levels of data quality. This section provides information on potential data type (Section 4.2.1) and data uses (Section 4.2.2) for the project.

4.2.1 Data Types

Two types of data will be produced for the Seneca Depot Activity. Screening data are data generated by rapid methods of analysis with less rigorous sample preparation, calibration and/or QC requirements. Physical test methods (e.g., dissolved oxygen (DO) measurements, temperature, pH, moisture content, turbidity, conductance, etc.) have been designated by definition as screening methods. Screening data are to be used for screening purposes. A summary of screening methods are presented in Table 3.

Definitive data are analytical data that are suitable for final decision-making. All definitive data will be generated using rigorous analytical methods such as approved USEPA SW-846 reference methods. A summary of definitive methods are presented in Table 4. Tables 5-A and 5-B present sample containers, preservatives, and holding times for soils/sediment and aqueous samples, respectively. Table 6-A through Table 6-N present target analyte list for various analytical methods and Table 7-A through Table 7-G present quality control requirements for various analytical methods.

In addition to the above referenced two types of data, non-measurement data acquisition may be required for each project. The data that may be required include:

- Climate,
- Geology and soils,
- Hydrogeology,
- Local relevant habitats, and
- Threatened and endangered species.

4.2.2 Data Uses

Data produced under the project will be used by various users for a variety of purposes, such as determining the nature and extent of contamination at a hazardous waste site, assessing priorities for response based on risks to human health and the environment, determining appropriate cleanup actions, determining when remedial actions are complete, and determining compliance with regulatory permit limits and environmental standards. The data may be used in all stages in the investigation of a SWMU, including site inspections, RI/FS, remedial design, treatability studies, and removal actions. In addition, the data may be used in enforcement/litigation activities.

4.3 DATA QUALITY INDICATORS

This section presents a brief introduction of the data quality indicators (DQIs) including precision, accuracy, representativeness, completeness, comparability, sensitivity and defensibility. The quantitation method for each indicator is discussed in this section. The measurement performance criteria for each indicator identified for the project is presented in Table 7-A through Table 12.

4.3.1 Precision

Precision is a measure of mutual agreement among individual measurements of the same property, usually under prescribed conditions. Assessing precision measures the random error component of the data collection process. Precision is determined by measuring the agreement among individual measurements of the same property, under similar conditions, and is calculated as an absolute value.

The degree of agreement, expressed as the relative percent difference (RPD), is calculated using the formula below.

$$\text{RPD} = \frac{(V_1 - V_2)}{\frac{(V_1 + V_2)}{2}} \times 100$$

where: V1 = value 1; V2 = value 2

Analytical precision can be assessed by analyzing matrix spike/matrix spike duplicate pairs, laboratory control spike (LCS)/laboratory control spike duplicate pairs, and laboratory analytical duplicate samples. Field precision is assessed by measurement of field duplicate samples. The objective for precision is to be within the established control limits for the methods. A note will be provided if RPD is not calculated due to missing data values, "less than" or "greater than" values, or other reasons. The control limits for precision are presented in Table 7-A through Table 7-G, Table 10-A through Table 10-E, and Table 12 and any exceedance of the values listed in the table will trigger corrective actions as presented in Section 11.

4.3.2 Accuracy/Bias

Accuracy is the degree of agreement of a measurement with an accepted reference or true value; bias indicates the systematic or persistent distortion of a measurement process that causes errors in one direction. The terms accuracy and bias are used interchangeably in this document. Accuracy measures the bias or systematic error of the entire data collection process. Sources of these errors include the sampling process, field and laboratory contamination, sample preservation and handling, sample matrix interferences, sample preparation methods, and calibration and analytical procedures. To determine accuracy, a reference material of known concentration is analyzed or a sample which has been spiked with a known concentration is reanalyzed. Accuracy is expressed as a percent recovery and is calculated using the following formula:

$$\%\ \text{Recovery} = 100 \times \frac{\text{measured value}}{\text{true value}}$$

Recoveries are assessed to determine method efficiency and matrix interference effects. Analytical accuracy is measured by the analysis of calibration checks, system blanks, quality control samples, surrogate spikes, matrix spikes, and other checks required by the selected analytical methods. Sampling accuracy is assessed by evaluating the results of field and trip blanks. Sampling accuracy is also maintained by frequent and thorough review of field procedures. The objective of accuracy is to meet the established control limits for the methods. A note will be provided if % recovery is not calculated due to missing data values, "less than" or "greater than" values, or other reasons. The

control limits for precision are presented in Table 7-A through Table 7-G and Table 10-A through Table 10-E and any exceedance of the values listed in the table will trigger corrective action requirements as presented in Section 11.

4.3.3 Representativeness

Representativeness expresses the degree to which data accurately and precisely represents a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition. Representativeness is achieved through proper development of the field sampling program. The sampling program must be designed so that the samples collected are as representative as possible of the medium being sampled and that a sufficient number of samples will be collected.

4.3.4 Completeness

Completeness is a measure of the amount of valid data obtained from a measurement system compared to the amount that was expected to be obtained under normal conditions. Data are complete and valid if they meet all acceptance criteria including accuracy, precision, and any other criteria specified by the particular analytical method being used. Data with minor exceedances in accuracy and precision may be considered usable based on a data usability assessment, which is presented in Section 8.7.

Field completeness will be estimated as the percentage of all planned samples that were actually collected and analyzed. The calculation is as follows:

$$\% FC = (A/P) \times 100$$

where,
%FC = Field Percent Completeness;
A = Actual number of samples collected; and
P = Number of planned samples to collect.

Laboratory completeness will be estimated as the percentage of all usable measurements and calculated as follows:

$$\%C = (U/T) \times 100$$

where:
%C = Percent completeness;
U = Number of measurements judged usable; and
T = Total number of measurements.

The objective is to generate a sufficient database with which to make informed decisions. To help meet the completeness objective, every effort must be made to avoid sample loss through accidents or inadvertence. The required completeness for a project will be defined by the SS-WP.

4.3.5 Comparability

Comparability expresses the confidence with which one data set can be compared to another. Comparability must be considered in designing the sampling program and the objective will be met by using standard methods for sampling and analyses specified in this report and by following techniques and methods set forth in the SS-WP.

Whenever definitive analysis is performed to confirm screening results, comparability criteria must be established and documented in the SS-WP prior to data collection. Comparability criteria must be determined for each matrix, analytical group (and analyte, if applicable), and concentration level.

4.3.6 Sensitivity and Quantitation limits

Sensitivity is the ability of the method or instrument to detect the target analytes at the level of interest. Method and instrument sensitivity is measured by developing Method Detection Limits (MDLs) for each analyte of interest. The MDL is a statistically derived value that represents the lowest concentration of an analyte that can be detected with 99 percent confidence that the analyte concentration is greater than zero. And MDL study is performed for each analyte, instrument and matrix and represents the lowest concentration detectable under those conditions.

The quantitation limit (QL) is the minimum concentration of an analyte that can be routinely identified and quantified by a laboratory. The QL is usually three to five times the MDL. For multipoint calibrations, the lowest point of the calibration curve should be at or below the QL. For one-point calibrations, the laboratory should analyze a check standard that contains all target analytes at or below the QL as proof that the analyte can be quantitated at that level.

4.3.7 Defensibility

Data defensibility is defined as data that are both relevant and reliable. This generic SAP was designed to improve data defensibility for the project. A few key elements that will ensure data defensibility are:

- Appropriate documentation, including Chain of Custody (COC) forms, project records and analytical traceability
- Using appropriate and approved analytical methodology
- Using NYSDOH ELAP-certified laboratories
- Appropriate sampling design, sample collection, sample handling, and sample storage
- Data validation
- Audits

4.4 METHOD DETECTION LIMITS, REPORTING LIMITS, AND INSTRUMENT CALIBRATION REQUIREMENTS

This section describes the terminology, procedures, and laboratory-established values for method detection and reporting limits (RL). Definitions for MDL and RL are described below.

4.4.1 Method Detection Limit (MDL) Study

The MDL is the minimum concentration of a substance that can be measured and reported with 99% confidence when the analyte concentration is greater than zero. The MDL is lower than the concentration at which the laboratory can quantitatively report. Laboratories determine their "best case" sensitivity for analytical methods by performing MDL studies. The MDL determinations are performed annually or when a major change to the analytical method, instrumentation, or preparation (e.g., extraction) procedure occurs. The MDL study shall be conducted by following the procedure as described in 40 CFR 136 Appendix B. The MDLs achieved by the chosen laboratory within one year prior to the analysis of project samples should be less than or equal to one-half the sample reporting limits.

4.4.2 Method Detection Limit Verification

MDL verification is performed on an MDL check sample spiked at approximately 2 times the reported MDL to confirm the MDL or to extend the use period of the MDL. The MDL verification can be performed on each instrument immediately following an MDL study to validate the MDL. In addition, after the initial MDL study, the MDL verification can be performed quarterly in lieu of the annual MDL study. The MDL verification sample shall be taken through all the preparatory and determinative steps used to establish the MDL values. The MDL is verified if the laboratory can

reliably detect and identify all analytes in the check sample by the method-specified criteria. If the method has no confirmation criteria, the check sample must produce a signal that is at least 3 times the instrument's noise level. If the MDL is not verified, the laboratory shall determine the cause(s) of the verification failure, correct the problem, and repeat the MDL verification. An alternative measure for the MDL verification failure is to spike at successively higher concentrations until the verification criteria are met, and use the first successful concentration as the reported MDL. The laboratory and project chemist shall ensure the newly established MDL still meets the PQOs.

4.4.3 Sample Quantitation Limit (SQL)

Frequently, QLs for specific samples are adjusted for dilutions, changes to sample volume/size and extract/digestate volumes, percentage of solids, and cleanup procedures. These QLs are referred to as SQLs.

4.4.4 Reporting Limit (RL)

The laboratory participating in any project under this contract shall compare the results of the MDL demonstrations to the RL for each analyte. Laboratory RLs should be at least 3 times the achievable laboratory MDL and ideally 10 times the achievable laboratory MDL. The laboratory shall also verify RL by including a standard at or below the RL as the lowest point on the calibration curve. All results shall be reported at or above the MDL values; however, for those results falling between the MDL and the RL, a laboratory validation flag shall be applied to indicate the analyte was detected, but the concentration is an estimation. No results shall be reported below the MDL. The RL must be at or below the project required RLs specified in the SS-WP.

4.4.5 Project Required Reporting Limit

The project required reporting limit for a target analyte is the numerical value identified for the project. It may be an ARAR or TBC identified for the project such as maximum contaminant levels (MCLs), a risk-based concentration level, a reference-based standard, or a technological limitation. Some commonly used ARARs, TBCs, and other benchmark values are listed in Tables 1-A, 1-B, and Table 6-A through Table 6-N. Project required reporting limit will be specified in the SS-WP based on the specific site condition.

Environmental decision-making may be adversely affected by the failure to meet project required reporting limits. Therefore, laboratory RLs must be less than the project required reporting limits.

Because of uncertainty at the quantitation limit, project SQLs should be no greater than one-third of the project required reporting limit and ideally one-tenth of the project required reporting limit.

4.4.6 Contract Required Quantitation Limit (CRQL)

CRQL is the minimum level of reliable quantitation acceptable under the USEPA Contract Laboratory Program (CLP). The contract Statement of Work (SOW) for the CLP gives CRQLs, and they are used for RLs (after adjustment for %moisture and dilution). The CLP CRQLs are set at the concentration of the lowest non-zero standard in the calibration curve. Organic analytes that are positively identified below the CLP CRQL are reported as present, but at an estimated concentration (with a "J" flag). The laboratory RL should be reported below the CRQL under the CLP program. Inorganic analytes reported at a concentration above the laboratory's RLs but below the CLP CRQL are flagged with a "B".

4.4.7 Instrument Calibration

Measuring and testing instrument shall have an initial calibration and shall be recalibrated/verified at scheduled intervals against certified standards that have known and valid traceability to recognized national standards. Calibration intervals for each item shall be, at a minimum, in accordance with manufacturer's recommendations as defined in the instrument manual, the analytical method, the NYSDEC ASP, and the project specific QA requirements.

Calibration standards shall be maintained and used in an environment with temperature, humidity, and cleanliness controls that are compatible with the accuracy and operating characteristics of the standards. An inspection will be made during the instrument calibration to evaluate the physical condition of the instrument. The purpose of the inspection is to detect any abnormal wear or damage that may affect the operation of the instrument before the next calibration. Instrument found to be out of calibration or in need of maintenance or repair will be identified and removed from service.

The laboratory QA Officer shall be notified if the instrument is found to be out of tolerance during inspection and calibration. The corrective actions to be taken include evaluating the validity of previous inspection or test results; evaluating the acceptability of the items inspected or tested since the last calibration check; and repeating the original inspections or tests using calibrated instrument when it is necessary to establish the acceptability of previous inspections or tests. Specifics regarding QC checks and verification of equipment stability are presented in Table 7-A through 7-G for laboratory instrument and Table 11 for field instrument.

All measuring and testing instrument use shall have current documentation of the calibration status and calibration expiration date. Instrument history records for measurement and test equipment shall be used to indicate calibration status and conditions, corrections to be applied, results of in-service checks, and repair history. This will provide a basis for establishing calibration frequencies and for remedial action if the instrument is found out of calibration.

4.4.7.1 Laboratory Instrument Calibration

Analytical instruments shall be calibrated in accordance with the analytical methods. All target analytes reported shall be present in the initial and continuing calibrations, and these calibrations shall meet the acceptance criteria specified in Table 7-A through Table 7-G. All results reported shall be within the calibration range. Results outside the calibration range are unsuitable for quantitative work and only give an estimate of the true concentration. For SW6010 and SW6020, results shall be within the working linear range determined by linear range studies performed in accordance with the method and NYSDEC ASP. Records of standard preparation and instrument calibration shall be maintained.

Records shall unambiguously trace the preparation of standards and their use in calibration and quantitation of sample results. Calibration standards shall be traceable to standard materials. Instrument calibration shall be checked using all target analytes identified in the project-specific requirements and surrogates. If no project-specific analytes are identified, the analytes listed in Table 6-A through Table 6-N shall serve as the default analytes for the method.

This applies equally to multi-component analytes (e.g., PCBs). All calibration criteria shall satisfy NYSDCE ASP at a minimum. The initial calibration (ICAL) must be verified by a second source standard. Multipoint calibrations shall contain the minimum number of calibration points specified in Table 7-A through Table 7-G with all points used for the calibration being contiguous. If more than the minimum number of standards is analyzed for the ICAL, all of the standards analyzed shall be included in the ICAL. The only exception to this rule is a standard at either end of the calibration curve can be dropped from the calibration, providing the requirement for the minimum number of standards is met.

Acceptance criteria for the calibration are presented in Table 7-A through Table 7-G. Analyte concentrations are determined with either calibration curves or response factors (RFs). For gas chromatography (GC) and GC/mass spectrometry (GC/MS) methods, when using RFs to determine analyte concentrations, the average RF from the ICAL shall be used. The continuing calibration shall not be used to update the RFs from the ICAL. The continuing calibration verification (CCV) cannot be used as the LCS, except for methods that do not involve sample preparation (e.g., volatile organic analysis). A CCV is to be performed daily before sample analysis (unless an ICAL and second-source standard verification is performed immediately before sample analysis) and as required by the applicable method and the SAP (Table 7-A through 7-G gives the appropriate frequencies.). In addition, the concentration used for the CCV sample shall be at or below the middle of the calibration curve. Finally, the lowest standard used must be at or below the RL for each analyte in the method.

If calibration acceptance criteria are not met, corrective action will be implemented and recalibration conducted, and the laboratory will reanalyze all samples since last successful calibration verification.

4.4.7.2 Field Instrument Calibration

The frequency of calibration for field instruments will be performed at the intervals specified by the manufacturer or more frequently as conditions dictate, but daily as a minimum.

To ensure comparability between sample data of similar samples and sample conditions, standard solutions and material traceable to the National Institute of Standards and Technology (NIST) or USEPA-published standards/protocols will be used to calibrate the field instruments.

Table 11 summarizes requirement for field equipment calibration, maintenance, testing, and inspection.

4.5 QUALITY CONTROL ACTIVITIES

QC elements relevant to screening data are presented in Section 6.0. This section presents QC requirements relevant to analysis of environmental samples that shall be followed during all analytical activities for fixed-base, mobile, and field laboratories producing definitive data. The purpose of these QC activities is to produce data of known quality that satisfy the project quality objectives (PQOs). These activities provide a mechanism for ongoing control and evaluation of data quality measurements through the use of QC materials.

Laboratory quality control samples (e.g., method blanks and LCS samples) shall be included in each preparation batch with the field samples. A project analytical batch (PAB) is a group of samples (not exceeding 20 environmental samples plus associated laboratory QC samples) that are similar in composition (matrix) which are extracted or digested at the same time and with the same lot of reagents and analyzed together as a group. The term “PAB” also extends to cover samples that do not need separate extraction or digestion (e.g., volatile analyses by purge and trap). The laboratory shall determine optimum batch size by the number of samples of similar matrix with the ability to be processed simultaneously through the entire preparation and analytical process within a normal work shift. In order to preserve the integrity of the sample designation, it is required whenever possible that all samples received on a given date be prepared and analyzed in the same PAB. The identity of each PAB shall be unambiguously reported with the analyses so that a reviewer can identify the QC samples and the associated environmental samples. All references to the analytical batch in the following sections and tables in this SAP refer to the PAB.

The following sections summarize quality control activities for the Seneca Army Depot Activity including laboratory selection requirement and QC sample requirement. Table 13 presents a summary of QC sample types and general requirements for QC samples. Frequency of project QA/QC sample collection and requirements, if varied from this generic SAP, will be specified in the SS-WP.

4.5.1 Laboratory Certification, Qualification, and Selection

To be selected for project chemical analysis, the laboratory should be certified by the NYSDOH ELAP program. The following four laboratories have been identified as potential laboratories for the project.

1) Severn Trent Laboratories, Inc.
   Tel: (617) 901-7306
   Contact: Rick Carr

   Severn Trent Laboratories, Inc.
   (STL Pittsburgh)
   301 Alpha Drive
   Pittsburgh, PA 15238
   Tel: 412-963-7058
   Contact: Mr. David Miller

   Severn Trent Laboratories, Inc.
   (STL Buffalo)
   10 Hazelwood Drive, Suite 106
   Amherst, NY 14228
   Tel: 716-691-2600
   Contact: Tony Bogolin

2) Columbia Analytical Services
   1 Mustard St., Suite 250
   Rochester, NY
   Tel: (585) 288-5380
   Contact: Mike Perry/Mark Wilson

3) AmeriSci Boston
   8 School Street
   East Weymouth, MA 02189
   Tel: 781-337-9334
   Contact: Bud Gibson

For each specific project, the project team will identify appropriate laboratory that conforms to the requirements presented in this SAP. In brief, the laboratory should follow the requirements presented below:

- For the analysis of any aqueous samples for a parameter or category of parameters for which laboratory certification exists pursuant to NYSDOH ELAP Certification, the laboratory should be certified for that specific parameter or category of parameters pursuant to NYSDOH ELAP Certification;
- For the analysis of non-aqueous samples using specific analytical methods contained in the USEPA Publication SW-846, "Test Methods for Evaluating Solid Waste", third edition, update IIF, January 1995, as amended and supplemented, for a parameter or category of parameters for which certification exists pursuant to NYSDOH ELAP Certification, the laboratory will be certified for that specific parameter or category of parameters pursuant to NYSDOH ELAP Certification or, at a minimum, have obtained temporary approval to analyze regulatory samples pursuant to NYSDOH ELAP Certification;
- The reporting limits for chemicals of potential concern should be within the limits specified in the SAP or SS-WP;
- The laboratory should follow the QA/QC procedures described in the NYSDEC ASP;
- The laboratory should report the analytical results consistent with the NYSDEC ASP requirement and those specified in the SAP (Section 8.2.1);
- The laboratory shall provide an electronic data deliverable (EDD) in accordance with the NYSDEC ASP requirement (Exhibit H) and the requirements presented in Section 8.

The laboratory identified for the project will be specified in the plans-WP.

4.5.2 Sample Receipt Requirements

The laboratory shall comply with the following specifications for sample receipt:

- The laboratory shall sign air bills upon receipt and keep copies in the project file.
- Shipping container custody seals shall be inspected and the condition documented.
- Condition of the samples shall be documented in the Cooler Receipt and Inspection Form with signature and date of person checking samples. This form will be included with the hardcopy report.
- The pH of preserved samples shall be checked with pH paper upon receipt and documented.
- Any breakage, discrepancy, or improper preservation shall be noted by the laboratory as an out-of-control event and shall be documented on the Cooler Receipt and Inspection Form with the corrective action taken. The Cooler Receipt and Inspection Form shall be signed and dated by the

custodian or the project manager of the laboratory. The laboratory project manager shall notify Parsons of discrepancies and any noncompliant issues in shipments within 24 hours of sample receiving. Sample log-in information shall be emailed or faxed to Parsons Project QA Manager or project chemist within 24 hours of sample receiving. Sample log-in information shall be emailed or faxed to Parsons project chemist within 28 hours of sample receipt.

4.5.3 Laboratory Control Sample (LCS)

The LCS is a blank matrix (contaminant-free water or an inert solid such as glass beads or Teflon® chips) that is spiked with a known concentration of all target analytes. Each analyte in the LCS shall be spiked at a level less than or equal to the midpoint of the calibration curve (The midpoint is defined as the median point in the curve, not the middle of the range).

The LCS shall be carried through the complete sample preparation and analysis procedure. At least one LCS shall be included in every PAB. If more than one LCS is analyzed in a single PAB, results from all LCS samples shall be reported. The failure of any analyte in the LCS shall require appropriate corrective action, including possible qualification of the failed analyte in all associated samples.

4.5.3.1 LCS Control Limits

The LCS control limits are presented in Table 7-A through Table 7-G and Table 9-A through Table 9-G. The limits are based on those specified in the NYSDEC ASP and the USEPA Region 2 SOPs. The laboratory may use in-house LCS control limits. However, those limits must be within the LCS control limits listed in the tables, if applicable. The performance of the LCS is evaluated against the control limits. When an analyte in the LCS exceeds the upper or lower control limit and no corrective action is performed or the corrective action is ineffective, the appropriate flag, consistent with the USEPA Region 2 SOPs, shall be applied to all affected results. Once an LCS has failed (as specified in Table 7-A through Table 7-G), corrective action is required.

4.5.3.2 LCS Corrective Action

If a sample fails based on the criteria presented in Table 7-A through Table 7-G, corrective action is required. The corrective action requirement applies to all analytes that exceeded the LCS control limits, even if one specific analyte's exceedance was not the trigger of LCS failure.

If an LCS fails, an attempt must be made to determine the source of error and find a solution. All the findings and corrective action should be documented. If a systematic problem is found, the problem should be resolved and system control reestablished. Following the reestablishment of control, all samples in the PAB shall be re-prepared and reanalyzed for the out-of-control analyte(s). The

corrective action applied shall be based on professional judgment in the review of other QC measures (i.e., surrogates). If an analyte falls outside the LCS control limits a second time or if there is not sufficient sample material available to be reanalyzed, then all the results in the PAB for that analyte will be flagged in accordance with the USEPA Region 2 SOPs. The recoveries of those analytes subject to corrective action must be documented in the case narrative, whether flagging is needed or not.

4.5.4 Matrix Spike/Matrix Spike Duplicate (MS/MSD)

A matrix spike (MS) and matrix spike duplicate (MSD) is an aliquot of sample spiked with known concentrations of all target analytes. The spiking occurs prior to sample preparation and analysis. Each analyte in the MS and MSD shall be spiked at a level less than or equal to the midpoint of the calibration curve for each analyte. Only project samples shall be used for spiking. The MS/MSD shall be designated on the chain of custody. MS and MSDs are treated as environmental samples.

The MS/MSD pair is used to document potential matrix effects associated with a site. Parsons project managers must select the samples for MS/MSD analysis. The sample replicates will be collected in the field and will be used by the laboratory to prepare and analyze the appropriate MS/MSDs. Only one soil sample container may be necessary for the parent sample, the MS sample, and the MSD sample with the exception of volatile organic analysis (VOA).

A site-specific MS/MSD should be specified for each media (e.g., any different soil, water, or sediment) at each site during each sampling event. Project managers should designate the MS/MSD and determine whether they are site specific based on the project requirements. A minimum of one MS and one MSD shall be designated by the project manager for each site and included for every 20 field samples (i.e., collect up to 20 field samples followed by two additional samples designated as MS and MSD). More than one MS/MSD pair may be submitted as part of the sample group of environmental samples; however, project managers must coordinate with the laboratory providing analytical services for most cost effective sampling. Based on the projects size and duration, it is possible that not every sample delivery group will include an MS/MSD pair. This is acceptable provided the overall project requirements are met.

The performance of the MS and MSD is evaluated against the QC acceptance limits given in Table 7-A through 7-G and Table 10-A through 10-E. If either the MS or the MSD is outside the QC acceptance limits, the data shall be evaluated to determine whether there is a matrix effect or analytical error and whether the analytes in all related samples shall be qualified according to the USEPA Region 2 SOPs. The laboratory should communicate potential matrix difficulties to Parsons so an evaluation can be made with respect to the PQOs.

4.5.5 Surrogates

Surrogates are compounds similar to the target analyte(s) in chemical composition and behavior in the analytical process but not normally found in environmental samples.

Surrogates are used to evaluate accuracy, method performance, and extraction efficiency. Surrogates shall be added to all environmental samples, controls, and blanks, in accordance with the method requirements.

Whenever a surrogate recovery is outside the limits presented in Table 8 or required by the method, corrective action must be performed. If systematic problems are found, the problems should be resolved and system control reestablished. After the reestablishment of control, the affected sample(s) should be re-prepared and reanalyzed. If corrective actions are not performed or are ineffective, or if sufficient sample volume is not available for reanalysis, the appropriate flag, consistent with the USEPA Region 2 SOPs, shall be applied to the sample results. Table 7-A through Table 7-G present corrective action and flagging criteria for various methods.

4.5.6 Internal Standards (IS)

ISs are known amounts of standards added to a portion of a sample or sample extract and carried through the entire determination procedure. They are used as a reference for calibration and for controlling the precision and bias of the analytical method.

ISs shall be added to all environmental samples, controls, and blanks, in accordance with the method requirements.

When the IS results are outside of the acceptance limits, corrective actions shall be performed. If systematic problems are found, the problems should be resolved and system control reestablished. After the reestablishment of control, the affected sample(s) should be re-prepared and reanalyzed. If corrective actions are not performed or are ineffective, or if sufficient sample volume is not available for reanalysis, the appropriate flag, in accordance with the USEPA Region 2 SOPs, shall be applied to the sample results.

4.5.7 Retention Time (RT) Windows

RT windows are used in GC, ion chromatography (IC) and high performance liquid chromatography (HPLC) analysis for qualitative identification of analytes. They are calculated from replicate analyses of a standard performed on multiple days. The procedure and calculation method are given in SW-846, Method 8000C. The center of RT window is established for each analyte and surrogate using the RT of the mid-point standard of the ICAL. For non-MS methods, the RTs for each analyte are

updated daily using the absolute RTs from the calibration verification performed at the beginning of each PAB.

If a significant shift in RTs is observed, the analyses should be halted and the instrumentation should be inspected to identify the cause of the shift. After any systematic problems have been resolved and system control has been reestablished, reanalyze all samples run after the shift occurred. If corrective actions are not performed, the appropriate flag, in accordance with the Region 2 SOPs, shall be applied to the sample results.

4.5.8 Interference Check Samples (ICSs)

ICSs are used in inductively coupled plasma-atomic emission spectra (ICP-AES) and Inductively Coupled Plasma-Mass Spectra (ICP-MS) analyses only and contain known concentrations of both interfering and analyte elements.

The ICSs are used to verify background and interelement correction factors.

The ICSs are run at the beginning of each run sequence for SW6010B and SW6020B.

When the ICS results are outside of the acceptance limits given in Table 7-C and Table 7-D, corrective action shall be performed. After the system problems have been resolved and system control has been reestablished, reanalyze the ICSs. If the ICS results are acceptable, reanalyze all affected samples. If corrective action is not performed or the corrective action was ineffective, the appropriate flag, in accordance with the USEPA Region 2 SOPs, shall be applied to all affected results.

4.5.9 Method Blank

A method blank is an analyte-free matrix carried through the complete sample preparation and analytical procedure. The method blank is used to assess possible contamination resulting from the preparation or analytical process. A method blank shall be included in every PAB.

The presence of analytes in a method blank at concentrations greater than the MDL indicates the need for further assessment of the data. The source of contamination should be investigated and measures must be taken to correct, minimize, or eliminate the problem if the concentration exceeds the RL or CRQL. For common laboratory contaminants (e.g., methylene chloride, acetone, phthalates), the concentration found in the method blank must not exceed the limits specified in Table 7-A through 7-G. No analytical data shall be corrected for the presence of analytes in blanks. When an analyte is detected in the method blank and in the associated samples and corrective actions are not performed

or are ineffective, the appropriate flag, as described in the USEPA Region 2 SOPs, shall be applied to the sample results.

4.5.10 Equipment Blank

An equipment blank is a sample of American Society for Testing and Materials (ASTM) Type II reagent grade water poured into or over or pumped through the sampling device, collected in a sample container, and transported to the laboratory for analysis. These may also be called rinse blanks or rinsate blanks.

Equipment blanks are used to assess the effectiveness of equipment decontamination procedures.

Equipment blanks shall be collected immediately after the equipment has been decontaminated and included for each sampling event as appropriate. The equipment blank samples shall be analyzed for all parameters requested for the environmental samples collected at the site. The frequency of collection for equipment blanks will be specified in the SS-WP.

When an analyte is detected in the equipment blank, the appropriate flag, as described in USEPA Region 2 SOPs, shall be applied to all sample results from samples collected with the affected equipment.

4.5.11 Trip Blank

The trip blank consists of a volatile organic compound (VOC) sample vial filled in the laboratory with ASTM Type II reagent grade or organic-free water, transported to the sampling site, handled like an environmental sample and returned to the laboratory for analysis. Trip blanks are not opened in the field. Trip blanks are only submitted when samples are collected and analyzed for VOC analytes.

Trip blanks are used to assess the potential introduction of contaminants from sample containers or during the transportation and storage procedures. At least one trip blank should be prepared for each group of coolers that contain samples for VOC analysis delivered at the same time. In accordance with the USEPA Region 2 (1989) CERCLA Quality Assurance Manual, an aqueous trip blank is not required when non-aqueous samples are collected.

When an analyte is detected in the trip blank and in the associated samples, the appropriate flag, as described in the USEPA Region 2 SOPs, shall be applied to all sample results from samples in the cooler with the affected trip blank.

4.5.12 Field Duplicate (Replicate) Samples

Field duplicates are two (or more) field samples taken at the same time in the same location. They are intended to represent the same population and are taken through all steps of the analytical procedure in an identical manner. These samples are used to assess precision of the entire data collection activity, including sampling, analysis, and site heterogeneity.

Duplicate samples are collected simultaneously or in immediate succession, using identical recovery techniques, and are treated in an identical manner during storage, transportation, and analysis. The samples may be either collocated samples or subsamples (replicates) of a single sample collection. Examples of collocated samples include ambient air monitoring samples, surface water grab samples, and side-by-side soil core samples, while subsamples may be taken from one soil boring or sediment core. The sample containers are assigned a unique identification number in the field. Specific locations should be designated for collection of field duplicate samples prior to the beginning of sample collection.

It is recommended to collect one sample per week or 10% of all field samples per matrix, whichever is greater (USEPA, 2004b). Precision acceptance criteria are given in Table 12.

4.5.13 Laboratory Duplicate Samples

Laboratory duplicate samples, also known as analytical duplicates, demonstrate the precision of the analytical process within the laboratory. A minimum of one analytical duplicate sample shall be performed for every 20 field samples. Acceptance criteria are given in Table 12.

4.6 QUALITY CONTROL CHECKS

This section summarizes quality control checks including sample holding time compliance check, quantitation confirmation for samples analyzed using GC or HPLC, standard material check, and supplies and consumables check.

4.6.1 Holding Time Compliance

To maximize representativeness of sample results, all samples will be extracted and/or analyzed within the holding times specified in each method. Tables 5-A and 5-B present the maximum holding times allowed for each method. Extraction or analysis performed after the expiration of the holding time will result in the qualification of the results during the data validation procedures. The holding time requirement should be applied to all samples including samples diluted for reanalysis and samples reanalyzed due to quality control issues.

Any samples extracted and/or analyzed beyond project required holding time for extraction or analysis may be resampled and resubmitted for analysis.

It should be noted that the NYSDEC ASP requires holding times to be calculated from the verified time of sample receipt (VTSR) and not from the sample collection date and time. Tables 5-A and 5-B list both technical holding time requirement and NYSDEC ASP holding time requirement. The laboratory shall extract and/or analyze each sample within both the technical holding time and NYSDEC ASP holding time requirement presented in Tables 5-A and 5-B.

4.6.2 Quantitation Confirmation

Quantitative confirmation of results at or above the RL for samples analyzed by GC or HPLC shall be required, unless otherwise specified in the SS-WP, and shall be completed within the method-required holding times. If holding times are exceeded and the analyses are performed, the results shall be flagged according to the USEPA Region 2 SOPs. For GC methods, a second column is used for confirmation. For HPLC methods, a second column or a different detector will be used. Unless otherwise specified or overlapping peaks are causing erroneously high results, the lower of the two confirmed results shall be reported as the primary result. The column used for both the primary and confirmation results shall be indicated on the sample reports. The associated calibration and QC results (including method blank, LCS, MS/MSD, surrogates and ISs) shall be submitted for both columns so that sample results can be appropriately evaluated.

4.6.3 Standard Materials

Standard materials, including second source materials, used in calibration and to prepare samples shall be traceable to NIST, USEPA, American Association of Laboratory Accreditation (A2LA) or other equivalent source, if available. If an NIST, USEPA, or A2LA standard material is not available, the standard material proposed for use shall be included in an addendum to the laboratory QA manual submitted to Parsons before the analyses. The standard materials shall be current, and the following expiration policy shall be followed: The expiration dates for standards shall not exceed the manufacturer's expiration date or one year from the date of receipt, whichever comes first. Expiration dates for laboratory prepared stock and diluted standards shall be no later than the expiration date of the stock solution or material or the date calculated from the holding time allowed by the applicable analytical method, whichever comes first. Expiration dates for pure chemicals shall be established by the laboratory and be based on chemical stability, possibility of contamination, and environmental and storage conditions. Expired standard materials shall be either revalidated prior to use or discarded. Revalidation may be performed through assignment of a true value and error window statistically derived from replicate analyses of the material as compared to an unexpired standard. The laboratory shall label standard and QC materials with expiration dates.

A second source standard is used to independently confirm the ICAL. A second source standard is a standard purchased from a vendor different from that supplying the material used in the ICAL. The second source material can be used for the continuing calibration standards and/or for the LCS. Two different lot numbers from the same vendor do not normally constitute a second source. However, when a project requires analyses for which there is not a separate vendor source available, the use of different lot numbers from the same vendor will be acceptable to verify calibration.

4.6.4 Supplies and Consumables

The laboratory shall inspect supplies and consumables prior to their use in analysis. The materials description in the methods of analysis shall be used as a guideline for establishing the acceptance criteria for these materials. Purity of reagents shall be monitored and documented. An inventory and storage system for these materials shall assure use before manufacturers' expiration dates and storage under safe and chemically compatible conditions. As part of the laboratory's maintenance program, service contracts are held on sufficient supplies. SOP's for routine maintenance of supplies and consumables shall be submitted for each laboratory performing analytical services as part of this project. Consistent with the Uniform Federal Policy for Quality Assurance Project Plans, the documentation should include the following:

- Supplies that will be used in the performance of analytical work
- All vendors for supplies and reagents
- Specifications for all supplies and reagents that could affect data quality (such as level of contamination, pesticide versus reagent-grade). Procedures that will be used to ensure supply cleanliness and reagent purity (such as recording reagent lot numbers)
- Procedures for measuring supply cleanliness
- Corrective action procedures for preventing the use of unacceptable supplies

The laboratory shall purchase or prepare sample containers in accordance with the specifications in the NYSDEC ASP (Exhibit I) and the SAP (Table 5-A and Table 5-B), unless specifically directed to do otherwise by Parsons. The individuals responsible for checking supplies and implementing corrective actions will be identified by the laboratory. Laboratory QA manuals, which include supplies and consumables inspection SOP, will be reviewed by Parsons project chemist before the analysis starts.

Supplies and consumables for field activities will be inspected by field team leader. Table 11 presents inspection requirement and Table 14 provides a critical supplies and consumable tracking log.

5.0 SAMPLING PROCEDURES

5.1 FIELD SAMPLING PROCEDURES

Field sampling procedures including field sample collection SOPs and field sample storage are presented in Section 16.

5.2 SAMPLE COLLECTION DOCUMENTATION

Documentation for sample collection includes sample container identification, field notes recording any observation during the sample collection, and the COC discussed in detail in the following section.

The sample label requirement is discussed in detail in Section 16. The information on the label will be preserved by covering the label with clear tape to minimize water damage during transit. Requirement for other field documentation (e.g., field logbooks and field data collection forms) is presented in Section 16.

5.3 SAMPLE HANDLING AND CUSTODY

A sample is physical evidence collected from a facility or from the environment. Controlling evidence is an essential part of the hazardous waste investigation and remediation effort. To accomplish this, proper sample handling and custody procedure should be followed. Table 16 illustrates the sample handling system.

5.3.1 Sample Identification

To assure traceability of the samples, each sample should be properly labeled in the field and be assigned a sample identification (ID). The Laboratory shall have a specified method for maintaining identification of samples throughout the Laboratory. Each sample and sample preparation container shall be labeled with the sample identifier. If the sample identifier is different from the sample ID assigned at the field, it shall be cross-referenced to the sample ID.

5.3.2 Sample Handling

The following summarizes the general sample flow:

- Sample collection, packaging, and shipment,
- Sample receipt and analysis,
- Sample archiving, and

- Sample disposal.

Table 16 identifies personnel primarily responsible for ensuring proper handling, custody, and storage or field samples during the above different stages of sample flow.

5.3.3 Sample Delivery

Unless specified in the SS-WP, samples will be delivered directly to the laboratory facility by overnight delivery service via common carriers (e.g., Federal Express and United Parcel Service Inc.). Samples will be grouped in sample delivery groups (SDGs) and each SDG should contain 20 or fewer field samples within a project. A SDG signifies a group of samples collected at one site or geographical area over a finite time period, and will include one or more field samples with associated QA/QC samples. Samples may be shipped to the Laboratory in a single shipment or multiple shipments over a period of time, depending on the size of the SDG. A SDG is defined by the following, whichever is most frequent:

- Each cooler of field samples received, or
- Each 20 field samples (including field QC samples) within an SDG, or
- Each 7 calendar day period (excluding Sundays and Government holidays) during which field samples in an SDG are received (said period beginning with the receipt of the first sample in the SDG).

Samples should be packaged, marked and labeled in accordance with the SAP (Section 16). Samples should be shipped in compliance with the most recent U.S. Department of Transportation (DOT) regulations for shipping hazardous and nonhazardous materials, and in accordance with the analytical methodology. Shipment papers, including bills of lading and airbills, should be retained by the laboratory with COC records. COC forms will be used as sample shipment forms.

5.3.4 Sample Custody

Sample custody procedures ensure accountability for the location and integrity of the sample at all times. Sample custody documentation for the project includes COC forms, custody seals provided by the laboratory, laboratory sample receipt forms, laboratory sample transfer forms, traffic reports (e.g., air bills), and sample ID.

A COC record accompanies the sample container from the laboratory to the field where the sample is collected, preserved, and then returned to the laboratory. The field sampling team should neatly and clearly fill out the COC form provided by the laboratory. Special care should be used to differentiate the number zero from the letter “O”, the number five from the letter “S” and the number one from the letter “I”. Each cooler shipped to the laboratory should contain its own COC form. The field

sampling team should file one copy of each COC in the project file, place the remaining copy (or copies) in a zip-top baggie and attach the baggie to the inside lid of the associated cooler. The laboratory's sample custody program must meet the criteria listed below.

- The laboratory has designated a sample custodian who is responsible for maintaining sample custody and for maintaining all associated records documenting sample custody.

- Upon receipt of the samples, the custodian signs the COC record and records the date and time the samples are received. The custodian then measures and records sample temperature (using the temperature blank if available) on a cooler receipt form, checks for proper preservation, and checks the original COC documents and compares them with the labeled contents of each sample container for correctness and traceability. In the event any discrepancy is found, or the cooler temperature is outside the acceptable range of 2 to 4^{o}C, the laboratory should immediately contact Parsons project manager as part of the corrective action process. Parsons project manager will notify the Army if samples are received outside the above listed temperature range.

- A qualitative assessment of each sample container is performed to note any anomalies, such as broken or leaking containers. This assessment will be recorded as part of incoming COC procedures. In the event any sample containers are received compromised, the laboratory should immediately contact the Parsons project manager as part of the corrective action process.

- The samples are stored in a secured refrigerator until analyses begin. Refrigerators will be maintained at 4 °C ± 2 °C, and the temperatures will be recorded daily.

- A copy of the COC and cooler receipt forms should be included in each laboratory data package.

Sampling packaging and shipment SOPs (including types of sample tags, labels, custody seals, and forms to be used, sample numbering system, and other sample handling and tracking information) are presented in Section 16.

5.3.5 Unused Sample and Extracts Storage

All samples should be submitted with more than enough volume for analysis (i.e., at least twice the volume required for analysis) and any remaining sample volume will be appropriately stored by the laboratory. The laboratory is required to retain unused sample volume and used sample containers for a period of 120 days after data submission. From the time of receipt until disposal, the laboratory shall maintain all samples and unused sample volumes at 4°C (±2°C) and protected from light. Samples and unused sample volumes must be stored separately from sample extracts and standards. The laboratory shall retain all sample extracts after analysis in bottles/vials with Teflon®-lined septa

and shall maintain stored extracts at 4°C (±2°C). The laboratory is required to retain the sample extracts for 180 days after data submission.

6.0 SCREENING ANALYTICAL METHODS

Screening or non-definitive analytical methods can be useful tools in generating quality environmental data. These methods should be selected as part of the overall systematic planning process and can serve to minimize sampling error, thereby minimizing costs. The various analytical screening methods that may be used for the project are shown in Table 3. Table 3 also presents a summary of RLs for screening methods. Table 17 summarizes calibration and QC procedures for the screening methods. The methods and QC procedures were taken from *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods* (USEPA SW-846, Third Edition, and its subsequent updates), *Methods for Chemical Analysis of Water and Waste* (USEPA 1979), *ASTM Annual Book of Standards* (1993), and from various manufacturers' literature. Specific methods for a project are to be selected from Table 3 unless a variance is requested. The list below is not intended to be all inclusive. Other appropriate methods based on site-specific PQOs will be provided in the SS-WP.

Methods acceptable to the NYSDEC will be utilized for the determination of the presence of free product in soil or water. Such method include, without limitation, visual identification of sheens or other visible product, measurable thickness of product on the water table, the use of field instruments, ultraviolet fluorescence, soil-water agitation, centrifuging, and hydrophobic dye testing (NYSDEC, 2002).

Field screening analysis should be conducted consistent with the NYSDEC DER-10, Section 2.1(g). In brief, field screening methods for all sampling matrices (soil, water, air, interior surfaces) can only be used for contaminant delineation if contaminant identity is known or if there is reasonable certainty that a specific contaminant may be present; or to bias sample location to the location of greatest suspected contamination. Field screening methods should not be used to verify contaminant identity or clean zones unless there has been a correlation study approved in advance by the Division of Environmental Remediation (DER) for the specific site where screening methods are proposed for verification. Where field screening is used, a SOP will be developed and a duplicate analysis of 10% of the samples will be conducted. Laboratory confirmation on 10% of the samples by a standard ASP method is required. There should be no bias in the selection of duplicate or LCSs, such as selecting positive detections for duplication or confirmation. The duplicate or confirmation analysis should be done on every 10^{th} sample, selected in the order they are presented for analysis. Laboratory confirmation occurs if the correlation between field screening and laboratory results are within +/- 30%. Analysis must be done by a Field Analyst with the following minimum qualifications: (1) Completion of a certification course or training by an experienced analyst who has demonstrated proficiency in the method; or, (2) Demonstration of the analyst's proficiency by correlation of the analyst's results with laboratory confirmation analysis.

7.0 DEFINITIVE DATA ANALYTICAL METHODS

This section presents sample preparation methods and analytical methods. The identified methods basically follow requirements and guidelines set out in the USEPA SW-846 Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, USEPA Region 2 SOPs, and NYSDEC Analytical Services Protocol (2000). These methods have been developed specifically for the highly variable environmental samples and are reviewed and updated on a frequent basis in order to obtain the best possible quality data. Although specific method updates are noted in this document, the most recent updates to USEPA SW-846 and the NYSDEC ASP should be used if specified in the SS-WP.

As with the screening procedures in Section 6, the following methods and associated quality control requirements are subject to project-specific objectives developed during the DQO or systematic planning process. Once adopted, modification of these method-specific quality control and corrective action requirements involves appropriate communication and demonstration that the variances are adherence to PQOs and are consistent with the USEPA and NYSDEC ASP program goals. The ultimate goal is the generation of the highest quality defensible data necessary for informed decisions affording the decision-makers or stakeholders, a known and documented level of acceptable risk associated with the respective decision(s).

Section 7.1 presents brief description of preparation methods and Section 7.2 contains brief description of analytical methods. Table 6-A through Table 6-N present target analyte lists for various analytical methods and Table 7-A through Table 7-G present quality control requirements for various analytical methods. Table 8 summarizes performance criteria for surrogate recovery, Table 9-A through Table 9-G provides QC limits for LCS, Table 10-A through 10-E specifies QC criteria for MS/MSD results, and Table 12 presents performance criteria for field duplicates and laboratory duplicates.

7.1 SAMPLE PREPARATION METHODS

In accordance with the NYSDEC DER-10 guidance, sample matrix cleanup methods will be performed if:

1. Petroleum contaminated soils, sediments, or other solids are analyzed for semivolatile organics (SVOCs), and the MDLs are elevated above the applicable remediation standard because of matrix interference;

2. GC peaks are not adequately separated due to matrix interference. A peak will be considered inadequately separated when a rise in baseline or extraneous peaks interfere with:

- the instrumental ability to correctly identify compounds present (including ISs and surrogates), and/or;

- the integration of peak area and subsequent quantitation;

3. So specified by the analytical method; or

4. Matrix interferences prevent accurate quantification and/or identification of target compounds.

7.2 ANALYTICAL METHODS

Analytical methods should be identified based on site-specific information and objective and should be specified in the SS-WP. This SAP has identified several commonly used analytical methods for the project and the corresponding performance criteria are presented in Table 7-A through 7-G. Any variation from the methods identified in this SAP or selection of an appropriate method not recorded in the SW-846 or NYSDEC ASP should be documented in the SS-WP and a SOP should be developed and recorded. For tissue analysis, methods for each analyte to be tested will be proposed and approved by the NYSDEC.

For all petroleum storage and discharge areas, sample analysis should be conducted pursuant to the requirements of Spill Technology and Remediation Series (STARS) Memo #1 - Petroleum-Contaminated Soil Guidance Policy. Samples taken in non-petroleum storage and discharge areas should be analyzed for the stored material. Analysis should be conducted using any GC method by a laboratory that is certified pursuant to NYSDOH ELAP for the category of parameters being analyzed.

7.3 ANALYTICAL SOPS

Table 4 presents a list of analytical methods that will be used for the project. A NYSDEC ASP program, which contains SOPs for the referenced analytical methods, is attached in Appendix B. SOPs for the other analytical methods can be found from various sources.

7.4 TARGET COMPOUNDS

Unless specified in the SS-WP, for each analytical method, target compounds should include those listed in the Target Compound List (TCL) presented in NYSDEC ASP Appendix C. TCL for various analytical methods are presented in Table 6-A through Table 6-N.

Tentatively identified compounds (TICs) will be reported in the laboratory deliverables. If TICs or unknown compounds are detected at concentrations in excess of the applicable standards, criteria, and guidance (SCG), they should be addressed in either of two ways listed below. If a contaminant

specific SCG does not exist for TICs and for unknown compounds, the generic SCG (class of contaminant, e.g. SVOCs) should be used.

1. If the area will be remediated and it is likely that concentration of the TICs/unknown compounds will be reduced by the remediation, the TICs/unknown compounds should be analyzed in post remediation samples to document that they no longer exceed the applicable SCG.
2. An attempt should be made to positively identify and accurately quantify the TICs/unknown compounds using an analytical method consistent with this section so that a remediation standard can be developed.

7.5 TISSUE SAMPLING AND ANALYSIS

If tissue analysis is required, the following QA procedures should be followed.

1. Analysis of lipid content is required for all organochlorine compounds.
2. For GC, detector systems other than mass spectrometers are required for identification and quantification of some analyte groups depending on the extraction method used during preparation of the tissue for analysis. Proposed methods should be proposed and approved prior to analysis.
3. General USEPA quality control recommendations for tissue are contained in the NYSDEC DER-10, Appendix 2C. Alternate QC requirements may be specified depending on the specific analysis being done.
4. The QAPP for tissue analysis should follow the outline in the USEPA publication “Preparation Aids for the Development of Category I Quality Assurance Project Plans” (EPA/600/8-91/003).
5. Tissue sampling should follow the current procedures for biota collection, preparation, and analysis as directed by the DER.

7.6 TOXICITY TESTING

If toxicity testing is required, the quality assurance procedures contained in the latest approved USEPA or ASTM methods or any method approved by the DER should be followed.

7.7 AIR SAMPLING

If air sampling is required, the SOPs specified in the method approved by the USEPA or/and NYSDEC for the sampling should be followed. QA procedures should follow the guidelines or direction of the USEPA and NYSDOH and should be recorded in the SS-WP.

8.0 DATA MANAGEMENT AND EVALUATION

The data reduction, verification, validation, assessment, and reporting procedures described in this section will ensure that: (1) the data are reviewed and documented; (2) transcription and data reduction errors are minimized; (3) complete documentation is maintained; and (4) the reported results are accurate, or qualified if necessary. Laboratory data reduction and verification procedures are required to ensure that the data deliverable(s) meet the overall project objectives. Data reduction, whether performed by instrumentation or manually, shall follow methodologies specified in the laboratory SOPs or approved analytical methods. Project-specific variations of general procedures, statistical approach, or formulas must be identified and be detailed in the SS-WP. Any variances from established procedures must be requested and approved in advance. Automated procedures shall be verified as required by USEPA's guidance on Good Automated Laboratory Practices (GALP, USEPA 2185); all software shall be tested with a sample set of data to verify its correct operation via accurate capture, processing, manipulation, transfer, recording, and reporting of data. Data are reported in hardcopy data package(s) and as EDDs.

8.1 DATA REVIEW REQUIREMENTS FOR SCREENING DATA

Parsons will complete a 100 percent review of all screening data. The screening data methods are identified in Table 3 and the calibration and QC requirements are presented in Table 17. Calibration and QC requirements not within acceptable limits will be recorded.

Screening data deliverables shall be prepared for all field analyses. The screening data performed at field shall be reported on the screening data report forms (as attached in Appendix C). All field and QC sample results, calibrations, and calibration verifications should be recorded in a field logbook or the data report forms to ensure proper verification of sample results. Parsons QA officer will be responsible for the review of the entire screening data report package, including the associated field records. The results of this review shall (1) determine if the project objectives have been met, and (2) calculate the completeness of the screening data for the project. These results shall be included in the screening data deliverable.

8.2 DATA REVIEW LABORATORY REQUIREMENTS FOR DEFINITIVE DATA

Scientifically sound data of known and documented quality that meet project quality objectives are essential for use in the decision-making process. Data review is the process whereby data are examined and evaluated to varying levels of detail and specificity by a variety of personnel who have different responsibilities within the data management process. This section presents requirements for the laboratory to conduct review of definitive data.

8.2.1 Laboratory Data Reporting Requirements

The laboratory shall submit a data report to Parsons within 30 (or otherwise specified by the SS-WP) calendar days of receipt of samples. Data report should consist of one hard copy of NYSDEC Category B (or equivalent) standard data package and an EDD. The laboratory deliverables should be consistent with the NYSDEC ASP requirements, presented in Appendix B of the ASP. All data shall be reported using the ASP Category B (or equivalent) and all deliverables will be in the CLP or CLP equivalent Format. The chemistry data package must contain adequate information and be presented in a clear, legible, concise, and consecutively paginated manner. The data package will include a sample data summary package and a sample data package. Data packages should be delivered in accordance with the schedule communicated from the project manager. Raw data (including electronic media) of all field samples, QC samples, standards, and blanks should be archived and be available upon request for 5 years from the date of generation in accordance with the USEPA (2005a) requirement.

8.2.1.1 Sample Data Summary Package

A Sample Data Summary Package shall be delivered separately (i.e., separated by rubber bands, clips or other means) directly preceding the Sample Data Package. Sample data forms shall be arranged in increasing project sample number order, considering both letters and numbers. The Sample Data Summary Package consists of copies of specified items from the Sample Data Package. The Sample Data Summary Package shall contain all data for all samples within one SDG of the Case and shall be ordered as follows.

1. NYSDEC Data Package Summary Forms
2. SDG Narrative
3. By fraction (VOA, SV, PEST, INORG, CONV) and by sample within each fraction - tabulated target compound results (Form I-ORG or Form I-IN) and tentatively identified compounds (Form I-ORG, TIC) (VOA and BNA only)
4. By fraction (VOA, SV, and PEST) - surrogate spike analysis results (Form II-ORG) by matrix (water and/or soil) and for soil, by concentration (low or medium)
5. By fraction (VOA, SV, and PEST) - matrix spike/matrix spike duplicate/matrix spike blank results (Form III-ORG) - as required by method.
6. By fraction (VOA, SV, and PEST) - QC Check Sample/Standard Recovery Summary - If required by method.
7. By fraction (INORG and CONV only) - duplicate sample results (Form VIIN)
8. By fraction (INORG and CONV only) - spike sample results (Form V-IN)

9. By fraction (VOA, SV, PEST, INORG, CONV) - blank data (Form IV-ORG and Form III-IN) and tabulated results (Form I-ORG and Form I-IN) including tentatively identified compounds (Form I-ORG, TIC)(VOA and BNA only).
10. By fraction (VOA and SV only) - internal standard area data (Form VIIIORG).

8.2.1.2 Sample Data Package

The Sample Data Package is divided into the following eight major units, if applicable: SDG case narrative, Contract Lab Sample Information Sheets, COC forms, CLP volatiles data, CLP semivolatiles data, CLP pesticide/aroclor data, and inorganic data. The CLP data for volatiles/semivolatiles/pesticide/aroclor data include QC summary, sample data, standards data, raw QC data, copy of calculations, and copy of extraction. The inorganic data portion includes inorganic sample results, QC data, verification of instrument parameters, raw data, copy of calculations, and digestion logs. The data package should be prepared consistent with the NYSDEC ASP and the forms specified in the NYSDEC ASP will be used for the data package. If the analysis of a fraction is not required, then that fraction-specific unit is not required as a deliverable.

The Sample Data Package shall include data for analyses of all samples in one SDG, including field samples, reanalyses, blanks, duplicates, LCSs, LCSDs, MSs, and MSDs.

The Laboratory shall retain a copy of the Sample Data Package for 365 days after final acceptance of data. After this time, the Laboratory may dispose of the package.

The Sample Data Package shall contain:

- Laboratory name and location (city and state);
- Project name and unique report ID number;
- Field sample ID number as written on custody form;
- Laboratory sample ID number;
- Matrix;
- Sample description;
- Sample preservation or condition at receipt;
- Date sample collected;
- Date sample received;
- Date sample extracted or prepared;
- Date sample analyzed;
- Method (and SOP) numbers for all preparation, cleanup, and analysis procedures employed;
- Preparation, analysis, and other batch numbers;
- Analyte or parameter;

- RLs adjusted for sample-specific factors (e.g., aliquot size, dilution or extraction factors, moisture content);
- Method detection limits;
- Analytical results;
- All confirmation data;
- Any data qualifiers assigned;
- Concentration units;
- All reported data will reflect any dilutions or concentrations. The dilution factor, if applicable, should be noted on the analytical report. If neat and/or diluted results are available, data from all runs should be recorded and reported;
- Percent moisture or percent solids (results of all soils, mulch, etc. are to be reported on a dry weight basis);
- Sample aliquot analyzed;
- Final extract volume;
- Case narrative describing all non-compliant issues;
- COC forms and sample receipt documentation;
- Verification of hold time compliance;
- Results for RL check standards for organic methods;
- Analytical batch control records including method blank results, LCS/LCSD and MS/MSD recoveries, and surrogate spike recoveries;
- Documentation that IS area counts and RTs meet criteria;
- Documentation that interference check samples met criteria for ICP and ICP-MS metals;
- Results for dilution test and post digestion spikes analyzed for metals;
- "Before" and "after" chromatographs of each manual integration (MI) event including the reason(s) for the MI, the signature of the analyst who performed the MI and the signature of the approver;
- Corrective action reports with problem, action, and results; and
- Completeness of the data.

8.2.1.3 Case Narrative Requirements

An important part of the laboratory documentation is the case narrative. The case narrative contains essential information that affords an informed evaluation of data usability. The case narrative shall be clearly labeled "SDG Narrative" and shall contain: laboratory name and location, case number; SDG number; sample numbers in the SDG, differentiating between initial analyses and re-analyses; contract number; project name and site location; and detailed documentation of any QC, sample, shipment, and/or analytical problems encountered in processing the samples reported in the data package.

Whenever data from sample re-analysis are submitted, the laboratory shall state in the SDG Narrative for each re-analysis, whether it considers the re-analysis to be billable, and if so, why.

The laboratory must also include any problems encountered: both technical and administrative, corrective actions taken, and resolution and an explanation for all data qualifiers (i.e. flags) applied to the data.

The SDG Narrative shall contain the following statement, verbatim: "I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package and in the computer-readable data submitted on floppy diskette has been authorized by the Laboratory Manager or his designee, as verified by the following signature." This statement shall be directly followed by signature of the Laboratory Manager or his designee with a typed line below it containing the signer's name and title, and the date of signature.

The SDG Narrative itself must be signed in original signature by the Laboratory Manager or his designee and dated.

In summary, the following elements should be included in the case narrative:

- Cooler temperature, as required by the NYSDEC ASP.
- Table summarizing samples received, correlating field sample numbers, laboratory sample numbers, and laboratory tests completed.
- Discussion of sample appearance and integrity issues that may affect data usability (temperature, preservation, pH, sample container type or volume, air bubbles, multiphasic samples, excess headspace in soil VOC containers, the presence of multiple phases, etc.)
- Samples received but not analyzed and why.
- Discussion of holding time excursions for sample preparation and analyses.
- Analysis of all out-of-control or discrepancies of calibrations, continuing calibrations or QC sample results (surrogates, LCS, MS/MSD, post-digestion spikes, etc.), raw data/chromatograms and corrective actions taken.
- Identification of samples and analytes for which MI was necessary.
- Discussion of all qualified data and definition of qualifying flags.
- Discussion and recommendations of potential data usability of qualified data including detailed discussion of conditions associated with Q-flagged data.

8.2.1.4 Requirements for Reconstructed Total Ion Chromatograms

Reconstructed Ion Chromatograms (RIC) should be reported for each sample or sample extract. RICs must be normalized to the largest non-solvent component and contain the following header information:

- Sample number
- Date and time of analysis
- GC/MS instrument ID

IS and system monitoring compounds are to be labeled with the names of compounds, either directly out from the peak, or on a printout of RTs if RTs are printed over the peak. If automated system procedures are used for preliminary identification and/or quantification of the target compounds, the complete data system report must be included in all Sample Data Packages in addition to the RIC. The complete data system report shall include all of the information listed below. For laboratories that do not use the automated data system procedures, a laboratory "raw data sheet", which contains the following information, must be included in the Sample Data Package in addition to the chromatogram.

- Sample number
- Date and time of analysis
- RT or scan number of identified compounds
- Ion used for quantitation with measured area
- Copy of area table from data system
- GC/MS instrument ID
- Laboratory file ID

In all instances where the data system report has been edited, or where MI or quantitation has been performed, the GC/MS operator must identify such edits or manual procedures by initialing and dating the changes made to the report.

8.2.1.5 Requirements for Reporting Compound Identification

For each sample, by each compound identified, the following shall be included in the data package:

a) copies of raw spectra and copies of background-subtracted mass spectra of target compounds listed in NYSDEC ASP that are identified in the sample and corresponding background-subtracted TCL standard mass spectra. Spectra must be labeled with NYSDEC sample number, lab file ID, date and time of analysis, and GC/MS instrument ID; compound names must be clearly marked on all spectra.

b) copies of mass spectra of organic compounds not listed in the TCL (TICs) with associated best-match spectra (three best matches).

8.2.1.6 Requirements for Reporting Compound Quantitation

The laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

8.2.1.7 Reporting Limits Requirements

Reporting requirements associated with RLs are presented as follows:

- MDLs and sample results should be reported to one decimal place more than the corresponding RL, unless the appropriate number of significant figures for the measurement dictates otherwise.
- Soil samples shall have results reported on a dry weight basis. A wet weight aliquot of sample equivalent to the method specified dry weight aliquot of sample should be taken for analysis. Alternatively, the lab may choose to use a consistent wet weight aliquot that is expected to be large enough to compensate for the moisture in the sample (e.g., 50% more) and use this as a consistent weight.
- If possible, samples should be analyzed undiluted and non-detects reported to the project specified RLs. RLs for minority constituents in highly contaminated samples may have to be adjusted for dilutions.
- If the non-detect "ND", "U", "<", or other lower limit reporting convention is used, then these terms must be defined (EM200-1-6).
- RLs should be below the CRQL, if applicable.

8.2.1.8 Environmental Data Significant Digits Reporting Requirements

Definitive analytical data possess some degree of uncertainty in the final reported values. Use of scientifically defensible and consistent numbers of significant figures in reporting analytical data allows the readers and users of these data to properly evaluate measurement uncertainty. This proper evaluation of data accuracy and precision facilitates the scientifically valid interpretation, summarization and subsequent reporting of these data. The recommendations stated in this section of the SAP do not set policy for determining the number of significant figures laboratories should use in reporting their data. However, subcontractors and Parsons staff are encouraged to use sound scientific judgment in choosing the appropriate number of significant figures and to be consistent in the number of significant figures used to report definitive analytical data. The laboratories and Parsons project team are encouraged to comply with *Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications* (ASTM Designation: E 29-02, 2002).

8.2.2 Manual Integrations (MI)

MIs are an integral part of the chromatographic analysis process; they should be used judiciously to correct any incorrect integration by the automated instrumentation and not as a routine procedure for the purpose of meeting calibration or method QC acceptance criteria. Improper use of MIs (for example, peak shaving or peak enhancement) are considered improper, unethical, or illegal actions if performed solely to meet QC requirements. MIs shall be done only as a corrective action measures. Examples of instances where MI would be warranted include, but are not limited to, co-eluting compounds resulting in poor peak resolution, a misidentified peak, an incorrect RT, or a problematic baseline. When MIs are used, the following procedures are to be implemented for documenting the event and for consistency in performing the MI:

- The laboratory should provide SOP for MIs, if warranted. This SOP shall specify when automated integrations by the instrument are likely to be unreliable, what constitutes an unacceptable automated integration, and how the problems should be resolved by the analyst. This includes procedures for the analyst to follow in documenting any required MIs.

- When MIs are performed, raw data records shall include a complete audit trail for those manipulations. The raw data records shall include the results of both the automated and manual integrations (i.e., "before" and "after" chromatograms of manually integrated peaks), notation of the cause and justification for performing the MIs, and date, and signature/initials of person performing the manual operations.

- All MIs must be reviewed and approved by the laboratory Section supervisor and/or the laboratory QA officer.

  Note: Both the primary and secondary reviews (analyst's and supervisory) may be performed electronically, provided all documentation and data integrity are maintained.

- All MIs must be identified in the case narrative. This will ensure consistency when MIs are performed and facilitate review and acceptance of manually integrated data.

8.2.3 Tentatively Identified Compounds (TICs)

TICs are compounds not associated with the calibration standards, which are identified in methods with MS detection. All peaks with a response greater than 10% of the nearest IS are potential TICs and should be examined and reported. Qualitative identification of TICs is performed by computer searches of standard reference libraries and TICs may be reported as a specific chemical or as a member of a chemical family. For each volatile sample, the Laboratory shall conduct a search to determine the possible identity of up to 10 organic compounds of greatest concentration that are not

system monitoring compounds or ISs and are not listed as volatile TCL. For each semivolatile sample, the Laboratory shall conduct a search to determine the possible identification of up to 20 organic compounds of greatest concentration, which are not surrogates or ISs and are not listed as semivolatile TCL. In performing searches, the NIST/USEPA/NIH (2005 or later) and/or equivalent, mass spectral library shall be used. Concentrations are estimated assuming a RF of 1 between the TIC and the nearest IS.

8.2.4 Laboratory Data Review Requirements

All analytical data generated by the laboratory shall be verified prior to submittal to Parsons. This internal data review process, which is multi-tiered, shall include all aspects of data generation, reduction, and QC assessment. Procedures for laboratory verification and validation of data should be summarized in the laboratory QA manual. Each result reported by the laboratory should undergo multiple levels of internal data review. The analysts and technicians provide primary data review for 100 percent of the definitive data at the bench level, secondary review should be performed by independent experienced QC personnel on 100 percent of the data, and the final data packages are reviewed by the laboratory's section supervisor, QA manager, customer service representative or project contact before submission to Parsons.

The following elements for review/verification at each level must be included, but not be restricted to, in the review conducted by the laboratory:

- Sample receipt procedures and conditions,
- Sample preparation,
- Appropriate SOPs and analytical methodologies,
- Accuracy and completeness of analytical results,
- Correct interpretation of all raw data, including all MIs,
- Appropriate application of QC samples and compliance with established control limits.
- Verification of data transfers,
- Documentation completeness (e.g., all anomalies in the preparation and analysis have been identified, appropriate corrective actions taken, and have been documented in the case narrative(s), associated data have been appropriately qualified, anomaly forms are complete), and
- Accuracy and completeness of data deliverables (hard copy and electronic).

8.2.5 Laboratory Data Evaluation

The calibration, QC, and corrective actions for definitive data are shown in Tables 7-A through Table 12. Data qualifiers shall be applied by the laboratory as part of their validation activities. The data qualifiers for definitive data should be specified in the data deliverable package. Flagging criteria apply when acceptance criteria are not met and corrective actions were not successful or not

performed. The data qualifiers are reviewed by the supervisor of the respective analytical sections after the first and second level reviews of the laboratory data have been performed. No qualifiers will be applied to TICs.

The laboratory QA section shall perform a 100 percent review of 10 percent of the completed data packages, and the laboratory project representative shall complete a final review on all the completed data packages.

Parsons will subsequently evaluate the flags applied by the laboratory as part of the data validation and usability assessment activities. The flags may be accepted, modified, or rejected. For all data qualifiers that are changed, Parsons will provide clear justification for those modifications based on project-specific quality objectives.

8.2.6 Method Blank Evaluation Guidance

The following criteria shall be used to evaluate the acceptability of the blank data, unless PQOs specify otherwise. For method blanks, the source of contamination shall be investigated and measures shall be taken to correct, minimize, or eliminate the problem if the concentration exceeds the RL (Use the limits specified in Table 7-A through 7-G for common laboratory contaminants.). If the RL is exceeded, the laboratory shall evaluate whether reprocessing of the samples is necessary, based on the following criteria: i) the method blank contamination relative to the measured concentration of any sample in the associated preparation batch, or ii) there is evidence the blank contamination otherwise affects the sample results. Except when the sample analysis resulted in a non-detect, all samples associated with method blank contamination and meeting these criteria shall be reprocessed in a subsequent preparation batch. If no sample volume remains for reprocessing, the results shall be reported with appropriate flag, along with any other appropriate data qualifier. If an analyte is found only in the method blank, but not in any batch samples, no flagging is necessary. Method blanks should also be examined to verify that any TICs present in the samples are not found in the blank. Method blank contamination must be addressed in the case narrative.

8.2.7 Laboratory Data Reduction

Data reduction is the process by which raw analytical data generated from laboratory instrument systems are converted into usable concentrations. The raw data, which may take the form of area counts, instrument responses or observations, are processed by the laboratory and converted into concentrations expressed in the parts-per-million (ppm) or parts-per-billion (ppb) range. Raw data from these systems include compound identifications, concentrations, RTs, and data system printouts. Raw data are usually reported in graphic form, bargraph form, or tabular form. The laboratories will follow the applicable data reduction SOPs for data reduction requirements. Concentration units are to be listed on reports and any special conditions, such as dry weight conversions will be noted. “Non-

detects" will be reported as less than the practical quantitation limit (PQL). Results reported greater than the MDL but less than the PQL will be reported as estimated and flagged by the laboratory.

8.3 DATA TRANSFORMATION AND DATA REDUCTION

Field personnel will record all field data in bound field notebooks and on standard forms. During processing of field data, validation checks will be performed by individuals designated by the project manager. The purpose of these checks is to identify "outliers;" that is, data which do not conform to the pattern established by other observations. Because of the limited number of observations, detailed statistical analysis of the data to be obtained during this project is not feasible, and the principal method of validation will be routine checks to assure that data are correctly transcribed and that reported identification codes and sampling information match the corresponding information in the field records. In addition, data will be compared against those obtained in previous investigations (where available) and against applicable standards and guidelines.

Although outliers may be the result of transcription errors or instrumental breakdowns, they may also be manifestations of a greater degree of spatial or temporal variability than expected. Therefore, after an outlier has been identified, a decision must be made concerning its further use. Obvious mistakes in data will be corrected when possible, and the correct value will be inserted. If the correct value cannot be obtained, the data may be excluded. An attempt will be made to explain the existence of the outlier. If no plausible explanation can be found for the outlier, it may be excluded, but a note to that effect will be included in the report. Also, an attempt will be made to determine the effect of the outlier when both included and excluded in the data set, and the results will be discussed in the report.

After checking the validity of the data in the field notes, the field team leader or his designee will reduce the data to tabular form, when possible, by entering the data into data files. Where appropriate, the data files will be set up for direct input into the project database. At a minimum, 10% of the data entered into the database will be verified through a QC process. Subjective data will be filed as hard copies for later review by the project manager and incorporation into technical reports, as appropriate.

Sample calculations are contained in the method specifications. All concentration data shall be expressed in units of micrograms per liter (ug/L) or micrograms per kilogram (ug/Kg) dry weight, as appropriate for the matrix. The field measurements of pH, conductivity, turbidity, and temperature shall be reported in standard logarithmic, umho/cm, nephelometric turbidity units (NTUs), and degrees Celsius, respectively. All definitive analytical values and screening measurement values should be reported to appropriate significant figures consistent with the measurement. As an example, all water levels measured in wells will be reported to the nearest 0.01 foot and soil sampling depths will be reported to the nearest 0.1 foot.

All analytical results are carefully reviewed and formatted into final submittal form by experienced QC personnel. The data will be input into the project database, as described in Section 8.11.2.

8.4 DATA ASSESSMENT PROCEDURES

Scientifically sound data of known and documented quality that meet PQOs are essential for use in the decision-making process. Data assessment is the process whereby data are examined and evaluated to varying levels of detail and specificity by a variety of personnel who have different responsibilities within the data management process. For definitive data, the data assessment includes data verification, validation, and usability assessment. For screening data, data verification will be conducted to ensure data quality. There must be persuasive records that document data review activities to afford effective assessment of the data for its quality and usability. The data can then move forward with associated qualifiers indicating the overall usability of the data.

Data verification is the first step in data review. As used here, data verification is confirmation that the specified requirements have been performed, i.e., it is a completeness check. The detailed discussion of data verification is presented in Section 8.5.

Data validation extends this and is confirmation that the requirements for a specific intended use are fulfilled. Data validation is the systematic process of evaluating the compliance of the data with the pre-defined requirements of the project, including method, procedural, or contractual requirements and the comparison of the data with criteria based on the quality objectives documented in this SAP and the SS-WP. The purpose of data validation is to assess the performance associated with the analysis in order to determine the quality of the data. Data validation includes a determination, to the extent possible, of the reasons for any failure to meet performance requirements, and an evaluation of the impact of such failures on the usability of the data. Data validation procedure is presented in Section 8.6.

The data usability assessment is an evaluation based on the results of data validation and verification in the context of the overall project decisions or objectives. The assessment determines whether the project execution and resulting data meet PQOs. Both the sampling and analytical activities must be considered, with the ultimate goal of assessing whether the final, qualified results support the decisions to be made with the data. The requirements for data usability assessment are presented in Section 8.7.

8.5 DATA VERIFICATION

Data verification is the most basic assessment of data. Data verification is a process for evaluating the completeness, correctness, consistency, and compliance of a data package against a standard or contract. In this context, "completeness" means all required hardcopy and electronic deliverables are

present. Data verification will be performed by Parsons for all laboratory delivered data and field screening data.

8.6 ANALYTICAL DATA VALIDATION

Based on the information in the data package, a reviewer should be able to determine the precision, accuracy, representativeness, completeness, comparability, sensitivity, and defensibility of the data.

Data validation for laboratory data will be performed for all definitive sample results in accordance with the requirements contained in the analytical method, the SAP and SS-WP, the NYSDEC ASP, the USEPA Region 2 SOPs, the USEPA National Functional Guidelines for Data Review (USEPA, 2005b, 2004a). 100% data validation will be manually performed by the project chemist or personnel trained by the project chemist. The project chemist will review at least 20% of the data validated by the trained personnel and is responsible to oversee the whole data validation process. In performing the data validation, the raw data are spot-checked in accordance with the Region 2 SOP to evaluate whether there is any transcription error. The review of laboratory data will focus on the following subjects, if applicable:

- COC forms,
- Holding times, sample preservation, and sample conditions (e.g., percentage of solids),
- Instrument calibration and performance,
- Method blanks, trip blanks, equipment/rinsate blanks,
- MDLs and laboratory-established RLs,
- Analytical batch control records including laboratory spike recoveries and spike duplicate results, and MS recoveries and MSD results,
- Surrogate standard recoveries,
- IS areas and RTs,
- Confirmation results for explosives,
- Chromatograms and mass spectrums,
- Corrective actions,
- Formulas used for analyte quantitation,
- Laboratory and field duplicate results,
- Calculations supporting analyte quantitation,
- ICP serial dilution,
- ICS results,
- ICP linear range, and
- Completeness of data.

Data outliers that fall outside of the QC criteria outlined in this SAP or SS-WP (e.g., Tables 5-A/B, Table 7-A through Table 7-G, Table 8, and Table 9-A through Table 9-G, Table 10-A through 10-E, and Table 12) will be flagged with an appropriate qualifier consistent with the USEPA Region 2 SOPs. All data validation flags applied will be added to the validated data with explanation prior to submittal. Data validation flags are provided in Table 18-A and Table 18-B for inorganics and organics, respectively. An example form that will be used for the data validation is provided in Tables 19-A, 19-B, and 19-C. Table 20 summarizes data validation criteria for QA/QC parameters and corresponding data qualification action.

8.7 DATA USABILITY ASSESSMENT

A usability assessment evaluates whether data meet PQOs as they relate to the decision to be made, and evaluates whether data are suitable for making that decision. All types of definitive data (e.g., sampling, on-site analytical, off-site laboratory) are relevant to the usability assessment. The usability assessment is the final step of data review and can be performed only on data of known and documented quality (i.e., verified and validated data).

A data usability assessment report will be submitted to the project manager by the Parsons project chemist to summarize the usability of the validated data. The report will include:

- A summary of data validation results,
- Overall data usability and completeness,
- Evaluation of each data quality indicator (whether meet the criteria, what potential impacts on data usability),
- Any deviations (e.g., holding time, QC performance criteria, sample location, sample collection SOPs) from the SAP and/or the SS-WP and the impact of deviations on the usability of data,
- Any problems with documentation or custody procedures and the impact on the usability of data,
- Damaged samples and the usability of the associated data, and
- Any other relevant issues.

8.8 NON-DIRECT MEASUREMENT DATA EVALUATION

Site-specific non-direct measurement data evaluation will be specified in the SS-WP. Non-direct measurement data that will be collected for the project include

- Site data from all previous investigations, and
- measurements that are ancillary to addressing the project's objectives (e.g., meteorological data)

Existing data will be evaluated in combination with newly collected data. An evaluation consistent with the USEPA QA/G-5 (2002a) and USEPA (2005a) Uniform Federal Policy for Quality Assurance

Project Plans will be conducted to assess whether existing data meet the current project's acceptance criteria before the existing data are used for decision-making and will be recorded in project-specific work plan.

8.9 RECONCILIATION WITH USER REQUIREMENTS

Project results will be reconciled with the requirements defined by the data user or decision maker. Based on site-specific DQOs, the approach of data reconciliation will be discussed in SS-WP or SAP. Limitations on the use of the data will be reported in the project technical report.

8.10 ELECTRONIC DATA REPORTS

The laboratory shall provide an EDD in the format as specified in the NYSDEC ASP (Exhibit H) and in this generic SAP. Minimum specifications and requirements for EDDs are attached in Appendix D.

The laboratories will submit both a hard copy and an electronic copy of the analytical data for environmental, field and laboratory QC samples. The EDD shall contain the same information as described for the hard copy deliverable. Electronic deliverables should be reported with no discrepancies from the hard copy. In general, the EDD submittal will include:

- the laboratory's ID of each field sample,
- field sample IDs,
- analytes,
- results,
- data qualifiers and validation flags,
- concentration units, and
- applicable QC data.

Additionally, the calibration information should be included in the EDD if the laboratory has that capability.

The project technical data other than the chemical analysis results such as site information; well characteristics; hydrogeologic, geologic, and physical analysis results will be recorded by Parsons as electronic files under the project directory.

8.11 PROJECT DATA TRACKING AND ARCHIVING

This section presents information on project data tracking (Section 8.11.1), archiving (Section 8.11.2), storage and retrieval (Section 8.11.3), and submittal (Section 8.11.4).

8.11.1 Data Tracking

Project manager will be responsible for tracking data as they are collected, transformed or reduced, transmitted, analyzed, and submitted. Reports produced during each of the above phase will be submitted to project manager and archived in project files to ensure the data are properly tracked, reviewed, and validated for use.

8.11.2 Data Archiving

This section presents archiving procedures for electronic data (Section 8.11.2.1) and hardcopy data (Section 8.11.2.2).

8.11.2.1 Electronic Data Archiving

Electronic data shall be archived in project files and in electronic format by Parsons and the laboratory for the duration of the project or a minimum of five years, whichever is longer, or as dictated by project requirements (if longer than five years). The laboratory shall also provide for Parsons and Huntsville all files associated with the project in electronic media. The data packages must be retrievable for Parsons and Huntsville within seven calendar days. In the event of laboratory closure, all applicable documents and electronic media must be immediately transferred to Parsons or Huntsville.

The laboratory shall maintain electronic records sufficient to recreate each analytical event conducted pursuant to the SOW. The minimum records the laboratory shall keep contain the following: (1) COC forms, (2) initial and continuing calibration records including standards preparation traceable to the original material and lot number, (3) instrument tuning records (as applicable), (3) method blank results, (4) IS results, (5) surrogate spiking records and results (as applicable), (6) spike and spike duplicate records and results, (7) laboratory records, (8) raw data, including instrument printouts, bench work sheets, and/or chromatograms with compound identification and quantitation reports, (9) corrective action reports, (10) other method and project required QC samples and results, and (11) laboratory specific written SOPs for each analytical method and QA/QC function in place at the time of analysis of project samples.

Parsons uses Windows (2000 or more recent version) system to perform electronic file operation and Oracle database or other appropriate programs to perform chemical analysis data management on

network computers. The software programs are commonly used and upgraded whenever software changes occur. Parsons performs scheduled electronic data backups of project files and performs periodic archiving of electronic media on a scheduled basis. Electronic project files are maintained on a no-fault server; a no-fault server minimizes data loss during hard-drive failure by operating and distributing data sequentially over four separate physical hard drives. Back-ups of project files on to magnetic tapes on the no-fault server are performed on a weekly basis and updated daily, Monday through Thursday, through a differential back-up. A differential back-up replaces backed-up files that are edited between each daily update differential back-up.

Electronic tape back-ups are stored in a fire proof box either at Parsons or at an off-site storage location. Weekly backups onto magnetic tape are retained for a minimum of three weeks prior to overwriting; however, the last back-up each month is retained without being overwritten.

8.11.2.2 Hard Copy Data Archiving

Hardcopy data shall be archived in project files by Parsons and the laboratory for the duration of the project or a minimum of five years, whichever is longer, or as dictated by project requirements (if longer than five years). The laboratory shall maintain hardcopy records sufficient to recreate each analytical event conducted pursuant to the SOW.

All field measurements and instrument check data will be entered into an electronic database where it will also be maintained. In addition, hardcopy of field measurements and field notes will be archived in project files by Parsons for the duration of the project or a minimum of five years, whichever is longer, or as dictated by project requirements (if longer than five years).

8.11.3 Data Storage and Retrieval

All hardcopy and electronic chemical analysis data, field sheets, log books, and other relevant field documents (e.g., health and safety meeting sign-in sheets, personnel daily frisking forms, daily instrument check sheets) will be maintained by Parsons at Parsons or at an off-site storage location. If stored, the data packages will be retrievable within seven calendar days.

8.11.4 Laboratory Data Submittal

After analytical results from laboratories are validated, the validated results will be submitted to the Army on a quarterly basis. If laboratory analytical results are decided not be validated based on the project needs, the original laboratory results will be submitted on a quarterly basis. Both hardcopy and electronic deliverables will be submitted. The Army will submit an electronic data copy to USEPA Region 2.

8.12 HARDCOPY DATA REPORT FORMS

The hardcopy data reports or forms shall conform to the formats identified in the NYSDEC ASP program. The NYSDEC ASP forms shall be used unless a variance is requested and approved in advance and that the forms included in the site specific work plan or SAP, can be verified that they contain at a minimum the information requested on the NYSDEC ASP forms. A complete list and description of forms is provided in the NYSDEC ASP. Other forms shall be included in the site-specific work plan, as needed.

For all analyses, at a minimum, the laboratory report will show traceability to the sample analyzed and will contain the elements presented below.

- Case narrative (identifies problems and corrective actions);
- Copy of signed COC;
- Cooler receipt forms documenting the date, time of receipt, condition of samples (including preservation) and labels, temperature of the shipping container, and verification of integrity of the custody seals;
- Laboratory name;
- Client name;
- Date of sample collection;
- Date of sample receipt;
- Date of sample extraction or preparation;
- Date of issue;
- Project name and unique identification number;
- Field sample name/number;
- Laboratory sample number;
- Sample matrix description;
- Analytical method description and reference citation for all analyses, preparation, cleanup procedures;
- Preparation, analysis and other batch numbers;
- Individual parameter;
- Analytical results with correct number of significant figures;
- All confirmation data, when performed;
- Date of analysis (first run and subsequent runs);
- Analysis time;
- Method reporting limits adjusted for sample-specific factors (i.e., aliquot size, dilution/concentration factors, moisture content;
- Method detection limits;

- Concentration units;
- Any data qualifiers assigned;
- Percent moisture or percent solids (all soils reported on dry weight basis);
- Any special conditions;
- Chromatograms, as needed;
- Sample aliquot analyzed;
- Final extract volume;
- Dilution or concentration factors (if dilutions result in non-detect values for all other analytes which showed detected concentrations in previous analyses, the results of both runs will be reported with the appropriate notations in the narrative);
- Initial and continuing calibration results;
- A cross-reference to identify applicable laboratory QC samples with field samples; and
- Corresponding QC summary report.

The laboratory reports should conform to the requirements presented in Section 8.2.1. QC data will be recorded on Contract Laboratory Program or CLP-equivalent QC summary forms for the appropriate tests and correlated to the analysis results by the laboratory lot control numbers. The QC results are used to prepare control charts for each test and matrix type. QC reports will contain the following items as appropriate:

- Narratives describing any non-compliant samples,
- Method blank, trip blank, equipment rinsate blank,
- Surrogate results,
- LCS/LCSD results,
- MS/MSD or MS/MD results, and
- Tuning results.

The laboratory will, as a part of the data reduction and validation process, confirm that its documentation is complete, sequentially paginated, and legible; qualitative identifications are accurate; calculations are accurate; and results are expressed in the appropriate units. The laboratory will also confirm that data documentation has been approved by the laboratory manager or designee.

Manual recording should be conducted legibly in ink, initialed and dated by the responsible person. Any changes in entries in laboratory notebooks or on computer-printed data shall be corrected by drawing a single line through the error, initialing, and dating the new entry. The use of correction tape or fluid is not acceptable. All changes made in the computer shall be traceable.

8.13 DATA ANALYSIS

Parsons uses windows (2000 or more recent version) system to perform general file/data processing and the Oracle database to perform chemical analysis data management on network computers. In addition, various software and/or computer codes will be used at different project stages for different data analysis purposes. The following lists some of the commonly used software/computer codes for the project:

- XLSTAT (version 6.1.9 by Addinsoft), used for background comparison or any other statistical comparison;

- The computer code AQTESOLV™ (Geraghty & Miller, 1994) or similar, and the method of Cooper *et al*. (1967) for confined aquifers or the method of Bouwer and Rice (1976) and Bouwer (1989) for unconfined conditions, slug testing data analysis;

- The USEPA (2004c) Software for Calculating Upper Confidence Limits (ProUCL version 3.00.02), risk assessment Exposure Point Concentration estimation;

- The Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK) developed by USEPA, risk assessment for child lead exposure;

- The Recommendations of the Technical Review Workgroup for Lead for an Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil (USEPA, 2003), risk assessment for adult industrial worker.

Software/computer codes used for project will be recorded in project technical document and project manager and technical personnel are responsible for identifying the appropriate software for the project and for using the most recent version of the software.

Detailed discussion of system backup can be found in Section 8.11.

9.0 PERFORMANCE ASSESSMENT AND SYSTEM AUDITS

Audits will include a careful evaluation of both field and laboratory quality control procedures. Audits of field procedures will be performed before or shortly after systems are operational. The audits will be conducted by an individual who is technically knowledgeable about the operation(s) under review. This section discusses procedures for both performance audits (Section 9.1) and system audits (Section 9.2).

9.1 PERFORMANCE AUDIT PROCEDURES

Performance audits are conducted by introducing control samples into the data production process. These control samples may include performance evaluation samples, field samples spiked with known amounts of analyte, and split field samples that are analyzed by two or more analysts within or without the organization.

9.1.1 Laboratory Performance Audits

In addition to conducting internal reviews and audits, as part of its established Quality Assurance program, the laboratory is required to take part in regularly scheduled Performance Evaluations and laboratory audits from State and Federal agencies. These are conducted as part of certification processes and to monitor the laboratory performance. The laboratory shall use the information provided from these audits to monitor and assess the quality of its performance. Problems detected in these audits shall be reviewed by the laboratory Quality Assurance Manager and laboratory management and corrective action shall be instituted as necessary.

The laboratory will be required to conduct an analysis of Performance Evaluation (PE) samples or provide proof that Performance Evaluation samples submitted by USEPA or a state agency have been analyzed within the past twelve (12) months.

9.1.2 Field Performance Audits

Unless specified by the site-specific work plan, field performance audits will not be conducted for this project. Field performance will be assessed using QA/AC results (e.g., trip blank, equipment/rinsate blank, field replicate analyses, sample condition upon receipt by the laboratory). Each blank analysis will be considered an indirect audit of the effectiveness of measures taken in the field to ensure sample integrity (e.g., field decontamination procedures). The results of the field replicate analyses are an indirect audit of the ability of each field team to collect representative sample portions of each matrix type. In addition, Parsons QA Officer will be responsible to review in detail field procedures and field logs to verify compliance.

9.2 SYSTEM AUDIT PROCEDURES

Systems audits are qualitative inspections and reviews of the quality assurance system used by some part of or the entire measurement system. The audits are performed against a set of requirements, which may be a quality assurance project plan or work plan, a standard method, or a project statement of work. The primary objective of the systems audits is to ensure that the QA/QC procedures are being followed.

Field and laboratory quality control procedures and associated documentation may be system audited. These audits will be performed once during the performance of the project. However, if conditions adverse to quality are detected or if the project manager requests, additional audits may occur.

System audits will also be performed by data users including USEPA Region 2, NYSDEC, and the Army. Generally, the audit covers the SAP development and approval and SOP development and approval.

9.2.1 Laboratory Systems Audits

As part of its Quality Assurance Program, the Laboratory Quality Assurance Manager shall conduct periodic checks and audits of the analytical systems. The purpose of these is to ensure that the analytical systems are working properly and that personnel are adhering to established procedures and documenting the required information. These checks and audits will also assist in determining or detecting where problems are occurring.

The laboratory Quality Assurance Manager will periodically review laboratory control samples. These samples will reflect the quality of the entire analytical method, the efficiency of the preparation method and the analytical instrument performance. When a problem is detected, the Quality Assurance Manager will assist the analyst and laboratory management in determining the reason and in developing a solution. Rechecking of systems will be conducted by the Quality Assurance Manager as required.

Parsons QA officer or his/her designee is responsible for reviewing the laboratory QA/QC manual and ensure the laboratory QA/QC procedures are consistent with the project SAP requirement.

9.2.2 Field System Audit Procedures

System audits of field activities will be accomplished by an inspection of all field site activities. Field system audit should be conducted at the beginning of any long-term field sampling program (i.e., >1 week) and will be conducted on an ongoing basis during the project as field data are generated, reduced, and analyzed. Field audits, if warranted, should be specified in the SS-WP.

During the field audit, the auditor(s) will compare current field practices with standard procedures. The following elements will be evaluated during a field system audit:

- All activities including sample collection, equipment calibration, decontamination, record keeping conducted in accordance with the generic SAP and/or site-specific work plan;
- All procedures and analyses conducted according to procedures outlined in the generic SAP and/or site-specific work plan;
- Sample documentation;
- Working order of instruments and equipment;
- Level of QA conducted per each field team;
- Contingency plans in case of equipment failure or other event preventing the planned activity from proceeding;
- Decontamination procedures;
- Level of efficiency with which each team conducts planned activities at one site and proceeds to the next; and
- Sample packaging and shipment.

All numerical manipulations, including manual calculations, will be documented. All records of numerical analyses will be legible, of reproduction-quality, and sufficiently complete to permit logical reconstruction by a qualified individual other than the originator. After completion of the audit, any deficiencies will be discussed with the field staff and corrections implemented. If any of these deficiencies could affect the integrity of the samples being collected, the auditor(s) will inform the field staff immediately, so that corrections will be implemented immediately. The audit will be performed by the project QA officer, project chemist, field team leader, or designees. A standard form of field audit report and field daily quality control report is provided in Appendix C.

Field system audit may also be conducted by regulators.

9.3 AUDIT REPORTS

Audit reports will be written by auditors who have performed the audit after gathering and evaluating all data. Items, activities, and documents determined by lead auditors to be in noncompliance shall be identified at exit interviews conducted with the involved management. Noncompliances will be logged and documented through audit findings, which are attached to and are a part of the integral audit report. These audit-finding forms are directed to Parsons project manager, the Army, and the regulators (contact information see Section 3) within fifteen days after the completion of the audit.

Serious deficiencies will be reported to the project manager within 24 hours to satisfactorily resolve the noncompliance in a specified and timely manner. All audit checklists, audit reports, audit findings, and acceptable resolutions are approved by the QAO prior to issue. Corrective actions should be followed if any noncompliance is noted in the audit report. Verification of acceptable resolutions may be determined by re-audit or documented surveillance of the item or activity. Upon verification acceptance, the QAO will close out the audit report and findings.

10.0 PREVENTATIVE MAINTENANCE

A preventative maintenance program is necessary to help prevent delays in project schedules, poor output performance or erroneous results in investigative operations. Preventative maintenance on laboratory analytical equipment used in this project will be performed contractually by qualified personnel. Maintenance of field equipment will be performed routinely for sampling events. More extensive maintenance will be performed based on hours of use, by a qualified servicing organization. Repairs, adjustments and calibrations will be recorded.

10.1 FIELD EQUIPMENT

The three elements of the field equipment maintenance program include normal upkeep of equipment, service and repair (when required), and formalized record-keeping of all work performed on each piece of equipment. This section addresses the normal equipment upkeep element of the maintenance program. For most of the equipment, normal maintenance will consist of cleaning outside surfaces, lubrication of all moving parts, and, if applicable, a battery level check and recharge or replacement as necessary. This program will include the maintenance of all monitoring, measuring, and test equipment returning from use or any equipment used on a daily basis. The frequency of maintenance checks will be dependent on the individual needs and use of each piece of equipment. Maintenance procedures will be only those necessary for keeping an instrument in service or in preparation for everyday use. It is beyond the scope of this document to cover repair procedures for each piece of equipment. Repair problems will be referred to the manufacturer or other qualified servicing organization.

The field team leader, or the designated personnel, will be responsible for keeping all maintenance records, making sure all equipment used is maintained properly, informing field team members of any specific maintenance requirements for equipment used at the site and shipping any instrument in need of repair to the correct source.

The field personnel responsibilities include maintaining each piece of equipment located at the site and the maintenance of equipment after use. A record of equipment maintenance and repair will be kept in the field logbook.

Table 11 summarizes requirement for field equipment calibration, maintenance, testing, and inspection. These requirements are also briefed discussed in the following sections.

10.1.1 Field Equipment Calibration

The frequency of calibration for field instruments will be performed at the intervals specified by the manufacturer or more frequently as conditions dictate, but daily as a minimum. To ensure comparability between sample data of similar samples and sample conditions, standard solutions and material traceable to the National Institute of Standards and Technology or USEPA-published standards/protocols will be used to calibrate the field instruments. Table 11 summarizes requirement for field equipment calibration.

10.1.2 Field Equipment Inspection

Equipment to be used during field sampling will be examined to certify that it is in proper operating condition. This includes checking the manufacturer's operating manual and the instructions for each equipment to ensure that all maintenance requirements are being observed. Field notes for previous sampling trips will be reviewed so that the notations on any prior equipment problem are not overlooked and all necessary repairs to equipment have been carried out.

10.1.3 Field Equipment Maintenance

Equipment, instruments, tools, gauges, and other items requiring preventive maintenance will be serviced in accordance with the manufacturer's specified recommendations and written procedures developed by the operators.

Manufacturer's procedures identify the schedule for servicing critical items in order to minimize the downtime of the measurement system. It will be the responsibility of the field team leader to adhere to the maintenance schedule and to arrange any necessary and prompt service as required. Service to the equipment, instruments, tools, gauges, etc., will be performed by qualified personnel. In the absence of any manufacturer's recommended maintenance criteria, a maintenance procedure will be developed by the operator based upon experience and previous use of the equipment.

Logs will be established to record maintenance and service procedures and schedules. All maintenance records will be documented and traceable to the specific equipment, instruments, tools, and gauges.

Critical spare parts for field equipment will be located in the Parsons office at the Seneca Depot (Building 125). Records documenting field equipment calibration, maintenance, testing, and inspection activities will be archived under project file.

10.2 RENTAL EQUIPMENT

Rental equipment used on the project should be obtained only from a certified rental supplier. The equipment will require a pre-receipt inspection to verify accuracy, maintenance and upkeep of the equipment. A receipt indicating that the equipment has been checked upon return will be required as well.

10.3 LABORATORY INSTRUMENT

An important factor in maintaining accuracy and precision, achieving required holding times, and addressing contract schedule is preventive laboratory instrument maintenance. As part of the laboratory's maintenance program, service contracts are held on critical analytical instruments. SOP's for routine maintenance of laboratory equipment shall be submitted to Parsons by each laboratory performing analytical services.

10.3.1 Laboratory Instrument Calibration

All laboratory instruments shall be calibrated in accordance with USEPA SW-846 analytical methodology and the requirements of the NYSDEC ASP.

10.3.2 Laboratory Instrument Maintenance

An important factor in maintaining accuracy and precision, achieving required holding times, and addressing contract schedule is preventive maintenance. As part of the laboratory's maintenance program, service contracts are held on critical analytical instruments. SOP's for routine maintenance of laboratory equipment are included as part of the laboratory QA manual and will be reviewed by project chemist before project starts. The SOPs submitted by the laboratory describe the procedures and documentation activities that will be performed to ensure that all analytical instrumentation and equipment are available and in working order when needed. The SOPs also discuss the ability to ensure that project schedules are met (e.g., availability of spare parts or spare instruments, instrument control (on-site and during storage), security, and availability (e.g., log-in/log-out procedures)).

Instrument and equipment maintenance logs must be kept to document analytical instrumentation and equipment maintenance, testing, and inspection activities.

11.0 NONCONFORMANCE/CORRECTIVE ACTIONS

A nonconformance is defined as an identified or suspected deficiency in an approved document, such as a technical report, calculation, or computer program; an item where the quality of the end item itself or subsequent activities using the document or item would be affected by the deficiency; or an activity that is not conducted in accordance with the established plans or procedures. When a significant condition adverse to quality is noted at the site or laboratories by the field staff and/or Project Chemist, the cause of the condition will be determined and corrective action taken to preclude possible repetition. Condition identification, cause, reference documents, and corrective action planned will be documented and reported to the Parsons project manager, Parsons QA officer, the USACE Project Chemist, and involved subcontractor management. Implementation of corrective actions will be verified by documented follow-up action. All project personnel have the daily responsibility to promptly identify and report any condition adverse to quality, as well as to solicit the approved corrective action.

Parsons project manager has overall responsibility to ensure that all corrective actions necessary to resolve audit findings are acted upon promptly and satisfactorily. The project manager shall ensure that no further work dependent on the nonconforming item or activity is performed until the nonconformance is corrected. Samples that are analyzed prior to the resolution of a nonconforming event will be re-sampled, and/or reanalyzed once the corrective action has been initiated and is proven effective.

A copy of each closed nonconformance report shall be included in the quality assurance file and shall be maintained by the Project QA Officer. A template of nonconformance and corrective action report is provided in Appendix C.

11.1 FIELD CORRECTIVE ACTION

A corrective action shall be initiated during the field work when precision, accuracy, completeness, representativeness or comparability are not met or changes are made in the field that do not meet the scope of work requirements or other conditions are identified that are not consistent with the SAP. To document, a report shall be filed which lists the problems encountered and the corrective action implemented. A stop-work order may be issued by the Project QA Officer, if no resolution can be reached.

11.2 LABORATORY CORRECTIVE ACTION

If QA results for a particular analysis are outside the performance criteria described in this SAP or site-specific work plan (e.g., performance criteria for DQIs presented in Section 4) corrective action

will be taken to ensure continued data quality. Corrective actions that may be taken include, but are not limited to:

- Rechecking calculations;
- Checking QC data on other samples;
- Auditing laboratory procedures;
- Repreparing and/or reanalyzing the sample if warranted;
- Accepting data with the acknowledged level of uncertainty; and
- Qualifying the data as unusable.

The laboratory QA Manager will be responsible for initiating laboratory corrective action within 48 hours of the time it was noted.

12.0 QUALITY ASSURANCE REPORTS TO MANAGEMENT

QA reports will be generated by Parsons and corresponding laboratories during the project. In addition, audit and performance evaluation reports will be submitted by auditors to management to ensure the quality of the project.

12.1 LABORATORY QA REPORTS

The laboratory will summarize pertinent QA/QC issues in the laboratory data package case narrative report. These reports will include discussions of any conditions adverse or potentially adverse to quality, such as:

- Any laboratory or sample conditions which necessitate a departure from the methods or procedures specified in this plan,
- Any missed holding times or problems with laboratory QC acceptance criteria, and
- The associated corrective actions undertaken.

Such reports shall not prevent early notification to project management of such problems when timely notice can reduce the loss or potential loss of quality, time, effort, or expense.

12.2 FIELD QA REPORTS

Any field-related QA memorandums or forms shall be forwarded by field team leaders to the project manager, who will ensure that the project QA officer receives copies. The project technical director and project manager (or designated individual) will review these reports for completeness and the appropriateness of any corrective actions. The reports will be retained in the project files, and will be summarized in the QA report included in the final project documents. Appropriate steps will be taken to correct any QA/QC concerns as they are identified. The Parsons project manager will ensure that the technical project manager is informed of any significant QA/QC developments.

12.3 REPORTS OF AUDIT AND PERFORMANCE EVALUATION

As discussed in Section 9.3, audit reports will be written by auditors who have performed the audit within fifteen days after the completion of the audit. Serious deficiencies will be reported to the project manager within 24 hours to satisfactorily resolve the noncompliance in a specified and timely manner. The audit reports are directed to Parsons project manager, the Army, and the regulators (contact information see Section 3).

12.4 PROJECT QA REPORTS

A project QA report will be submitted after the project sampling and analysis is completed as part of the technical report. The QA report will summarize the overall QA information of the project, including information of laboratory performance, field performance, system performance, audit findings, and corrective actions. In addition, both validated data and laboratory and field QC data will be presented. The laboratory QA reports, field QA reports, project audit reports, and corrective action reports will be used to assist in developing the final QA Report. The project QA report does not prevent internal QA memorandums or communications regarding QA issues.

The following elements, if applicable, will be addressed in the QA section or other section of the technical report:

- Project scope,
- Project description,
- Status of project,
- Sampling procedures (planned vs. implemented),
- Field quality control activities (planned vs. implemented),
- Analytical procedures,
- A summary of data usability assessments in terms of precision, accuracy, representativeness, completeness, comparability, and sensitivity,
- Any problems that could affect the quality of the data collected, the project schedule or the completion of the project,
- Changes in the project's experimental design, objectives, or staffing,
- The need for additional equipment to achieve project objectives, or any problems with equipment,
- Data presentation,
- Required corrective actions and effectiveness of corrective action implementation,
- Limitations on the use of measurement data generated, and
- Lessons learned

13.0 SAP REVISIONS AND DISTRIBUTION

This section presents procedures and requirements for SAP revisions (Section 13.1) and distribution (Section 13.2).

13.1 SAP REVISIONS

The generic SAP will be revised and updated every five years in accordance with USEPA (2005a) requirement, or when there are changes warranted in response to project needs, or when directed by the approval authority. The project manager, QAO, and project chemist are responsible to determine if any changes to the SAP are warranted and their impacts to the quality of the project. If a change is desirable, the change will be incorporated into the site-specific work plans or issued as addendum to the generic SAP and approved by USEPA Region 2 and NYSDEC. Changes to the original SAP will only be implemented after the revision has been approved.

The quality assurance officer is responsible for revising the SAP. All project personnel should consult the QAO for the most recent approved version of the SAP.

13.2 SAP DISTRIBUTIONS

Table 21 lists all individuals who should get a copy of the approved SAP, either in hard copy or electronic format, as well as subsequent revisions: All the individuals identified in Table 21 will also receive all revisions, addenda, and amendments to the SAP. These individuals are responsible for removing all outdated material from circulation, distributing revised or added material to update any copies within their organizations.

All project personnel performing work related to sample collection, data producing, data assessment, data management, and data utilization should read the applicable sections of the SAP and perform the tasks as described. A project personnel sign-off sheet is presented in Appendix E and all identified personnel should read and sign off on the applicable sections of the SAP before beginning the tasks. Supervisory or oversight personnel are responsible for communicating the requirements of the applicable portions of the SAP to those doing work.

13.3 SAP ARCHIVING

The approved generic SAP and project-specific work plan, including reviewers' comments and responses to reviewers' comments will be archived in the appropriate project file. The files will be retained for the duration of the project or a minimum of five years, whichever is longer, or as dictated by project requirements (if longer than five years).

14.0 SPECIAL TRAINING/CERTIFICATION

Qualifications for the quality assurance officer, field analysts, and data validators are specified in Section 3. In brief, field analysts should have: (1) completed a certification course or training by an experienced analyst who has demonstrated proficiency in the method; or, (2) demonstrated the proficiency by correlation of the analyst's results with laboratory confirmation analysis. Data validation will be performed by trained and experienced personnel. The lead validator will have at least two years experience and be familiar with USEPA Region 2 data validation requirements. The quality assurance officer should have the qualifications specified in the NYSDEC guidance.

Field sample collection team should be led by experienced engineer who has demonstrated proficiency in the sampling method. All onsite workers will also be current on their 40-hour Occupational Safety and Health Administration (OSHA) Hazardous Waste and Emergency Response (HAZWOPER) Certification. All work will be conducted in accordance with the Generic Site-Wide Health and Safety Plan for Seneca Army Depot Activity (Parsons, 2005).

All field personnel performing radiological surveys should receive a minimum 1-hour of radiological safety and fundamental training, as well as a minimum of 24 hours of onsite orientation and technique training. This will include briefing on the risk associated with radiological contaminants. All radiation scanning work onsite will be overseen by a Health Physicist/Radiological Safety Officer (HP/RSO).

All field personnel performing work involving Munitions and Explosives of Concern (MEC) and/or Material Potentially Presenting an Explosive Hazard (MPPEH) will receive proper training as specified in the Munitions Response and CERCLA Closure Project Safety Plan (PSP) and Health and Safety Plan for Seneca Army Depot Activity (Parsons, 2006). Required, site-specific training will be provided by the Senior UXO Supervisor or the UXO Safety Officer prior to field personnel initiation of site actions.

All UXO personnel assigned to positions of UXO Technician I, UXO Technician II, UXO Technician III, UXO Safety Officer, UXO Quality control Specialist, and Senior UXO Supervisor must meet the requirements set forth in the USACE (2004) Data Item Description (DID) OE-025.02, Personnel/Work Standards. UXO personnel will be U.S. citizens and graduates from one of the following schools or courses:

- U.S. Army Bomb Disposal School, Aberdeen Proving Ground, Maryland;
- The U.S. Naval Explosive Ordnance Disposal (EOD) School;
- The EOD Assistants Course, Redstone, Alabama; the EOD Assistants Course, Eglin AFB, Florida; or a DoD-certified equivalent course.

In addition, site UXO personnel and technicians will have graduated from an approved school or course and meet the requirements of CEHNC OE-CX Memorandum dated 14 March 2005, Implementation of Defense Explosives Safety Board Technical Paper 18, Minimum Qualifications for UXO Technicians and Personnel, Military Munitions Center of Expertise Interim Guidance Document 05-01, and will have a UXO roster database number.

The following subsections detail additional individual UXO personnel qualifications.

UXO Safety Officer (UXOSO)

The UXOSO shall have the following skills/knowledge:

- The ability to identify fusing, necessary precautions, and fuze condition; i.e. armed, functioned, or armed and functioning; how this condition can or will affect the munition payload should other forces be applied.
- The ability to recognize munition/ordnance types and to determine the hazards and make risk assessments. This includes identifying potential fillers, including those in extremely deteriorated condition; e.g., high explosives, fragmentation, white phosphorous, and chemical warfare material. UXOSO must also be able to determine if munitions can be moved before destroying or if the munitions must be blown in place (BIP); fragmentation radius; and, in the case of chemical warfare material, the potential down-wind hazard along with the engineering controls to mitigate risk.

Senior UXO Supervisor (SUXOS)

The SUXOS will have at least 15 years combined active duty in military EOD and contractor UXO experience, including at least 10 years in supervisory EOD and UXO positions. This individual will have documented experience with and/or specialized training in the type of UXO/MPPEH expected to be encountered.

As the most senior UXO qualified individual onsite, the SUXOS directly supervises all daily UXO/MPPEH activities. This individual is responsible for the successful performance of field teams, early detection and identification of potential problem areas, and instituting corrective measures. The SUXOS shall execute instructions from the Parsons site manager; document site conditions; photographically document operations; prepare project reports; and identify efforts to accomplish the statement of work. The SUXOS reports to the Parsons site manager.

UXO Technician III

This individual supervises a UXO team. This individual will have experience in OE clearance operations and supervising personnel. The UXO Technician III will have at least 10 years combined active duty military EOD and contractor UXO or material posing potential explosive hazard (MPPEH) experience

UXO Technician II

The UXO Technician II may be a UXO Technician I with at least five years combined military EOD or contractor UXO/MPPEH experience.

UXO Technician I

The UXO Technician I will not perform UXO procedures without the direct supervision of a fully qualified UXO Technician II (or above). A UXO Technician I may become a UXO Technician II with at least 5 years combined military EOD and contractor UXO/MPPEH experience.

UXO Quality Control Specialist (UXOQCS)

The UXOQCS will have experience in UXO/MPPEH clearance operations and supervising personnel. This individual will have at least 10 years combined active duty military EOD and contractor UXO/MPPEH experience. The UXOQCS will have the required quality control training, including at least two years of experience providing QC on similar projects.

UXO Sweep Personnel

Personnel who have received the 40-hour HAZWOPER training will be hired to fill positions on the visual surface sweep teams and the mag & flag survey teams under the direct supervision of a UXO Technician III. UXO sweep personnel will receive on-site training in UXO/MPPEH recognition avoidance and safety.

Laboratory analyst should complete training by the laboratory and with qualifications deemed appropriate by the laboratory. The laboratories selected to perform analyses must be certified under the Environmental Laboratory Approval Program, implemented by the New York State Department of Health, and be capable of providing complete environmental analytical services consistent with USEPA protocols and NYSDEC ASP protocols.

Any other project specific special training should be recorded in the site-specific work plan.

15.0 DOCUMENTS AND RECORDS

All project documents (e.g., generic SAP, audit reports, internal QA/QC memorandums, interim progress reports, final reports) and records (e.g., field records and notes, communication logs) will be organized and kept consistent with the project management plan prepared by Parsons. All project documentation will be filed in the permanent project files. All project files will be maintained for the duration of the project or a minimum of five years, whichever is longer, or as dictated by project requirements (if longer than five years).

All the following files will be archived after the project is complete:

1. Approved generic SAP and site specific SAP or work plan (including reviewers' comments, responses to reviewers' comments, addenda, and amendments),

- Sampling collection and handling records (e.g., field notebooks, operational record, global positioning system data, sampling instrument decontamination records, sampling instrument calibration logs, sampling location and sampling plan, drilling logs),

- Laboratory report (including chain-of-custody forms, sample receipt and tracking records including sample tags and shipping bills, case narrative, analytical log books, test method raw data and QC sample records, definitions of laboratory qualifiers, documentation of laboratory method deviations, and electronic data deliverables),

- Laboratory certification and QA manual,

- Computer documentation such as model input and output files as results of code and database test procedures,

- Audit reports/checklists, documentation of internal QA review, and corrective action reports,

- Interim progress reports and final reports,

- Billing receipts,

- Presentations to be made during and after the project,

- Communication logs, telephone logs,

- Documentation of deviation from methods,

- Data review reports, and

- Any other project related documents.

Electronic project files are maintained on a no-fault server and back-ups of project files on to magnetic tapes on the no-fault server are performed on a weekly basis and updated daily, Monday through Thursday.

Laboratory document control procedures shall be consistent with the NYSDEC ASP.

16.0 FIELD SAMPLING PLAN

This section presents a generic FSP, which in specific terms, specifies the requirements and procedures for conducting field operations and investigations at Seneca Army Depot (or Depot). This generic FSP has been prepared to ensure (1) the data quality objectives specified for the Seneca Army Depot are met, (2) the field sampling protocols are documented and reviewed in a consistent manner, and (3) the data collected are scientifically valid and defensible. A site-specific work plan shall be prepared to supplement requirements and procedures for conducting site-specific field operations and investigations for each specific project or task, and shall reference this SAP document as appropriate to prevent repetition of information.

16.1 INTRODUCTION

The National Contingency Plan specifies circumstances under which an FSP is necessary for Comprehensive Environmental Response, Compensation, and Liability Act response actions. For cleanup actions at the remedial investigation/feasibility study stage, the NCP requires lead agencies to develop sampling and analysis plans that provide a process for obtaining data of sufficient quality and quantity to satisfy data needs (40 CFR 300.430 (b)(8)). Such sampling and analysis plans must include a field sampling plan.

Guidelines followed in the preparation of this FSP are set out in the documents below:

- "Guidance for the Data Quality Objectives Process," (QA/G-4) (USEPA, EPA/600/R-96/055, August 2000a).
- "Data Quality Objectives Process for Hazardous Waster Site Investigations," (QA/G-4HW) (USEPA, EPA/600/R-00/007, January 2000c).
- "Guidance for Quality Assurance Project Plans," (QA/G-5) (USEPA, EPA/240/R-02/009, December 2002a).
- "Guidance on Choosing a Sampling Design for Environmental Data Collection," (QA/G-5S), (USEPA, EPA/240/R-02/005, December 2002b).
- "Guidance for Preparing Standard Operating Procedures," (QA/G-6), (USEPA, EPA/240/B-001/004, March 2001c).
- "Guidance for Data Quality Assessment: Practical Methods for Data Analysis," (QA/G-9), (USEPA, EPA/600/R-96/084, July 2000b).

All staff participating in SEDA activities are required to be familiar with this FSP. The FSP shall be in the possession of the field teams collecting the samples. All subcontractors shall be required to comply with the procedures documented in this SAP (including the FSP presented in this section) in order to maintain comparability and representativeness of the collected and generated data.

As discussed in Section 13, controlled distribution of the SAP (including the FSP presented in this section) will be implemented by Parsons to ensure the current approved version is being used. A distribution list is presented in Table 21.

16.2 PROJECT OBJECTIVES FOR FIELD SAMPLING ACTIVITY

This section presents the project objectives for field sampling activity. The subsections present a summary of project data quality objectives, types of sample analysis, and field activities.

16.2.1 Data Quality Objectives (DQOs)

DQOs define the type, quantity, and quality of data that are needed to answer specific environmental questions and support environmental decisions. The development of DQOs for a specific site and measurement takes into account project needs, data uses and types and needs, and data collection. These factors determine whether the quality and quantity of data are adequate for its end use. DQOs are implemented so the data are legally and scientifically defensible. DQOs for this program are described in greater detail in Section 4 of this document.

16.2.2 Sample Analysis Summary

The number and type of analyses will be determined on a per-task basis and will be specified in each site-specific work plan. Types and frequencies of QC samples (MS/MSD, trip blanks, equipment blanks, duplicates, etc.) required for all sampling activities are described in Section 4. Sample containers, preservatives, and holding time for soils/sediments and aqueous samples are provided in Tables 5-A and 5-B, respectively.

16.2.3 Field Activities

Potential field activities at the Seneca Army Depot include installation of system components (e.g., groundwater monitoring wells), test pit investigation and scanning, soil sampling, baseline groundwater sampling and subsequent process monitoring, building sampling, ordnance and explosives (OE) sampling and analysis, indoor air and ambient air monitoring, radioactive material sampling and analysis, investigation derived waste (IDW) disposal. These activities may include the following:

- Excavation;
- Soil boring sampling;
- Field soil screening test;
- Confirmation soil sampling;
- Stockpile soil sampling;

- Groundwater monitoring well installation;
- Groundwater monitoring well development;
- Water level measurements;
- Groundwater sampling;
- Field measurements of groundwater parameters (e.g., pH, turbidity, hardness, temperature, conductance, alkalinity, dissolved oxygen, oxidation-reduction potential, manganese, sulfide, carbon dioxide, ferrous iron);
- Sampling equipment decontamination;
- Aquifer testing;
- Building sampling and analysis;
- Ordnance and explosives sampling and analysis;
- Indoor air and ambient air monitoring;
- Asbestos material sampling and testing;
- Radioactive material sampling and analysis;
- Disposal of investigation derived waste; and
- Record keeping.

Field activities conducted at each site will be described in each SS-WP.

16.3 FIELD OPERATIONS

This section presents protocols for field operations including soil and rock description, site reconnaissance, preparation, and restoration, geophysical surveys, soil boring advancement, groundwater well installation, monitor well development, monitor well abandon, aquifer test, test pit excavation, survey, equipment decontamination, investigation derived waste disposal, and corrective action.

16.3.1 Soil and Rock Description

Lithologic logs of all borings and excavations, including well construction diagrams, must be provided for the Seneca Army Depot activities. Each log must include borehole identification, soil and rock description, sample depths, methods of sampling, sampling date, land surface elevation, borehole/excavation total depth, and test results such as blow counts. Soil and rock description is an important element for the boring logs and this section presents the procedure for field soil and rock description.

16.3.1.1 Soil Terminology

1. Color

   The color of the soil is described using color chips attached to the Geotechnical Gauge. The color of the soil when it is wet is the standard for comparison.

2. Texture/Fabric/Bedding/Stratification

   Texture is described as the relative angularity of the particles: rounded, sub-rounded, sub-angular, and angular. Fabric should be noted as to whether the particles are flat or bulky and whether there is a particular relation between particles (i.e., all the flat particles are parallel or there is some cementation). The bedding or structure should also be noted (e.g., stratified, lensed, non-stratified, heterogeneous, varved).

3. Burmeister (1958) Terminology/ Modifiers

   The following terms are used to further describe soils:

   a. And — Modifier which identifies a proportion of soil which ranges from 35 to 50 percent.

   b. Some — Modifier which identifies a proportion of soil which ranges from 20 to 35 percent.

   c. Little — Modifier which identifies a proportion of soil which ranges from 10 to 20 percent.

   d. Trace — Modifier which identifies a proportion of soil which ranges from 1 to 10 percent.

   e. + or - — Modifiers to indicate the extremes of ranges defined above, or that a grain size has more or less of a particular size material.

4. Density and Consistency

   The density of noncohesive granular soils is classified according to standard penetration resistance. These classifications are provided on the Geotechnical Gauge for sands, and for silts and clays, using standard split-spoon sampling techniques. The blow counts for the middle 1 foot (using a 2 foot long split spoon sampler) are used for the classification of density or consistency.

5. Plasticity

If a moist soil can be rolled into a thread, it is said to have some plasticity. Materials that cannot be rolled in this manner are non-plastic, or have very low plasticity. The degree of plasticity of the soil may be further measured by the ease with which this material may again be remolded. After reaching the plastic limit, the degree of plasticity may be described as follows:

a. High plasticity (CH) - The soil may be remolded into a ball and the ball deformed under extreme pressure by the fingers without cracking or crumbling.

b. Medium plasticity (CL) - The soil may be remodeled into a ball but the ball will crack and easily crumble under pressure of the fingers.

c. Low plasticity (CL, ML, or MH) - The soil cannot be lumped together into a ball without completely breaking up.

6. Moisture

Moisture content is estimated in the field according to four categories: dry, moist, wet, and saturated.

7. Petroleum Hydrocarbons (non-aqueous phase liquid/oil)

The presence of petroleum hydrocarbons (PHC) or non-aqueous phase liquid (NAPL) in soil samples will be described according to the terms described below:

a. No PHC present - The soil does not contain any visible staining or PHC in the soil pore space.

b. PHC staining - The soil contains PHC staining which is visible on soil grains only. The color of the PHC should also be described (i.e., black, brown, etc.).

c. PHC in soil pores - The soil contains PHC on soil grains and in soil pore spaces. The color of the PHC should also be described (i.e., black, brown, etc.).

16.3.1.2 Soil Description

Soils logged during test pit activities or recovered from soil and bedrock borings will be classified according to the ASTM D2487-92, Standard Classification of Soils for Engineering Purposes (Unified Soil Classification System), with descriptive text added to the Unified Soil Classification System (USCS) following the procedure outlined by the Burmeister (1958).

The following procedure specifically addresses the description of samples using split-spoons in association with drilling operations.

1. Measure, or observe the drilling crew measure, all parts of the drilling equipment that will affect the depth of the sample. These include the length of the drill bit, auger bit, any drilling subs, the length of the split spoons and sampling head, etc. The field crew must be cognizant of the depth of the drill hole and associated equipment at all times.

2. Soil samples will be retrieved from drilling operations as described in Section 16.4.2.

3. Immediately after opening the split spoon sampler, the contents of the sample will be screened for VOCs using a Flame Ionization Detector (FID) or Photoionization Detector (PID). The data will be recorded in the appropriate locations on the Boring Report Form. Readings will be taken at one to three locations along the split spoon sample with additional readings taken if additional distinctive zones are observed.

4. Split the sample length-wise to expose a clean sample face for classification of stratigraphic features and for sample collection.

5. Determine soil descriptions using a Geotechnical Gauge. Record descriptions on the Boring Report form or Test Pit Record form using the following order and format: Test pit soil description will be based on a clean view of the sidewall of a test pit.

    - Color (while wet);

    - Grain size;

    - Major soil component descriptor (CLAY, SILT, SAND, GRAVEL, PEAT), with modifiers as applicable (micaceous, fibrous, etc.);

    - Other components in decreasing order using the Burmeister Classification System to quantify amounts (and, some, little, trace with + or - as applicable);

    - Density from blow count data (if split spoon);

    - Other descriptive modifiers such as stratification, plasticity, staining, minor minerals (if recognizable), unique materials or features, and odor (if present);

- Moisture content (if the drilling method used does not interfere with the sample moisture and if the sample is above the water table) and presence of NAPL;

- Possible origins will be given if enough information is available (i.e. fill, alluvium, till, glacio-marine, etc) on the next line after the soil description in parentheses;

- In some areas, the soil (clay, silt, sand, peat) may only be a minor component to foreign debris. If this is the case, the field personnel should note down the approximate percentages of debris vs. soil;

- General debris types; and

- Cross sections of the excavation for test pits or trenches.

The following is an example of an acceptable soil description:

Light brown, coarse to fine micaceous SAND, some - Silt, little + coarse + Gravel, medium dense, well graded, weakly stratified showing grade bedded, minor iron-oxide stain on quartz grains, dry. (Alluvium)

Note: Acronyms and abbreviations may be used to save space on the log forms. Abbreviations and acronyms should be minimized to avoid confusion.

6. Descriptions of the soil contained in the sampler will be made while the soil remains in the split spoon sampler.

7. Record the penetration interval of the split spoon sampler on the log form.

8. Record the sample recovery of the split spoon sample on the log form. While determining the length, care must be taken to measure only material that represents true sample. Discount material that may be wash or slough material in the spoon. If recoveries fall below 25 percent (e.g., 0.5 feet from a 2 foot sampler), the driller must make alterations to his sample collection methods to improve recovery. Alterations must be approved by the Site Manager before they are implemented. Such alterations may include modifications to the sample catcher, driving a spoon or core barrel beyond its length to pack the sample tighter within the spoon, or changing the diameter of the split spoon or core barrel. If more soil volume is needed for physical or chemical determinations, a 3 inch diameter split spoon may be used in place of the standard 2 inch diameter spoon. All deviations from the standard 2 inch diameter by 2 foot long split spoon should be recorded on the Soil Boring form.

9. Collect a representative and continuous portion of the sample and place it in a glass sample jar. Jar size will be determined prior to field operations. Collected soil materials may subsequently be used as a reference sample or for other physical characterization and screening purposes.

10. Record the interval (i.e., location within the recovered split spoon) of the sample on the field log.

11. Visually estimate, based on sample recovery and blow counts, the range of recovery for the sample. For shallow sample intervals, a segment of the interval may not be represented due to cobbles obstructing (possibly indicated by higher blow counts) the tip of the spoon. In deep sample intervals residing below the water table, the deepest portion of the sample may have been washed out of the tip of the spoon due to a faulty ball valve at the top of the spoon or a worn sample catching basket.

12. Any deviation from standard drilling procedures and the applicable depth will be recorded in the main body of the log form or in the REMARKS section. Such things as modifications to the sample methods to improve recovery or changes in the drilling method must be recorded. In particular, record sections where there was no attempt to collect a sample or where a roller bit or some other method was used to advance the hole.

16.3.1.3 Rock Description

Bedrock descriptions are dependent on the classification of the rock types present (igneous, sedimentary, or metamorphic). The rock materials retrieved during coring operations will be described on the Core Boring Report (Appendix C), as applicable, using the following parameters:

- Color - The overall color of the rock, not a particular mineral;

- Grain Size - The size of crystals or clasts making up the rock;

- Texture - This applies only to igneous and some metamorphic rocks, and pertains to whether the rock is crystalline or glassy, equigranular, or porphyric in nature;

- Major Minerals – This applies to the identifiable minerals present as necessary as modifiers to the rock type, i.e. mica Schist, feldspathic Granite, quartz-mica Gneiss;

- Rock Type - Granite, Gneiss, Amphibolite, Argillite, Sandstone, Limestone, Greywacke, etc;

- Bedding and/or Foliation - Describes lineations within the rock. i.e. massive, poorly foliated, well bedded, cross-bedded, etc. The description in the log will include at least an approximate angle of any foliation or bedding, if present;

- Continuity - Joints and fractures, or the lack of, in the rock, cross-cutting veins of materials different from the primary rock type. Fracture, vein, and joint angles will be referenced to the foliation. The openness of any fracture or joint will be evaluated based on core recovery, weathering, fracture density, etc.

- Competence - The weathering features of the rock. Weathering features, combined with rock type and continuity, will give the overall hardness of the rock; and

- Other - Secondary minerals, folding features, etc.

Both the overall core length as well as individual pieces of core (greater than 4 inches in length) will be measured. The data are used for the calculation of Rock Quality Designation (RQD) factors and for the interpretation of fracture spacing. Core recovery will be recorded in two manners: as the ratio of core recovered to length of core run; and, as a percentage recovery (i.e. 3.5 feet of 5.0 feet cored, 70%). The RQD will be calculated by: 1) summing the length of all the pieces greater than or equal to 4 inches in length recovered in the core barrel; and 2) by dividing this sum by the cored interval length. The resulting value will be expressed as a percent and recorded in the Core Boring Report (Appendix C).

16.3.2 Site Reconnaissance, Preparation, and Restoration Procedures

Parsons will contact Under Ground Facilities Protection Organization (UFPO) at 1-800-962-7962 prior to any earthwork operations, trenching, or excavation. Areas designated for intrusive sampling shall be surveyed for the presence of underground utilities. Utility locations are determined using existing utility maps, and in the field, are verified using a hand-held magnetometer or utility probe. SOPs for utility line identification and drilling and excavation are presented in the Munitions Response and CERCLA Closure Project Safety Plan and Health and Safety Plan (Parsons, 2006). A pre-drilling checklist is attached in Appendix C. Field personnel should consult the project manager and finish the checklist before any intrusive activities. Parsons will notify the Army the planned locations of intrusive activities the Army's approval is warranted before any intrusive activities. A notification letter will be submitted to USEPA and NYSDEC one month before site activities such as intrusive activities and sampling activities. Vehicle access routes to sampling locations shall be determined prior to any field activity.

It should be noted that no construction work will be permitted during the 9 days of the annual deer harvest. Specific dates for calendar year (CY) 2006 and beyond have yet to be determined.

Construction work can be conducted any other time of the year. During the construction period, Parsons will notify the COR at the end of each week, what work is planned for the following week. The COR may stop work at any time when an imminent danger/serious safety violation is found.

A centralized decontamination area shall be provided for site vehicles and equipment. The decontamination area shall be large enough to allow storage of cleaned equipment and materials prior to use, as well as to stage drums of decontamination waste. The decontamination area shall be lined with a heavy gauge plastic sheeting, and designed with a collection system to capture decontamination waters. Solid wastes shall be accumulated in 55-gallon drums and subsequently transported to a designated waste storage area. Smaller decontamination areas for personnel and portable equipment shall be provided as necessary. These locations shall include basins or tubs to capture decontamination fluids, which shall be transferred to a large accumulation tank as necessary. The designated areas of decontamination shall be specified in the SS-WP.

Parsons will establish a field office at the Depot; at present it is located in Building 125, but may be moved prior to the initiation of work under the Munitions Response/CERCLA Closure Program. The specific-location of the field office will be identified in the SS-WP.

Each work site or sampling location shall be returned to its original condition when possible. Efforts shall be made to minimize impacts to work sites and sampling locations, particularly those in or near sensitive environments such as wetlands. Following the completion of work at a site, all drums, trash, and other waste shall be removed. Decontamination and/or purge water and soil cuttings shall be transported to the designated locations as described in Section 16.3.12.

16.3.3 Geophysical Surveys

General requirements for all geophysical surveys are: (1) the geophysical surveys should be supervised by a state licensed geologist or engineer, (2) the locations of boreholes logged with geophysical instruments shall be shown on a site map, (3) the locations of surface geophysical grid system layouts shall be shown on a site map, (4) the location of areas analyzed with subsurface geophysical techniques shall be shown on a site map (5) final results shall be presented in plan views and cross sections. Contours shall be used where appropriate, (6) the survey report shall present survey results as well as limitations of the method and data and, (7) the interpretation of the data shall be incorporated into the conceptual site model. Geophysical surveys at sites with MEC / MPPEH are discussed in Section 16.3.14.

16.3.3.1 Electromagnetic (EM-31) Survey

Electromagnetic (EM) -31 surveys may be performed at the Depot. The objectives of the EM-31 surveys will be to delineate waste boundaries, identify the location of buried metallic objects, and identify the locations of old disposal pits. The EM-31 method will typically be employed in conjunction with Ground Penetrating Radar (GPR) surveys so as to provide significant redundancy during the geophysical investigations.

16.3.3.1.1 EM-31 Survey Procedures

The electromagnetic data will be collected using both grid and profile based surveys. In general, the grid based surveys will use either a 10 foot by 10 foot or 20 foot by 20 foot grid spacing. The corners of the geophysical survey grids will be established using a registered NY State land surveyor. The individual EM-31 survey lines and station locations will be established using both hip chains and hand held compasses.

At the site where EM-31 data will be collected, a data logger will be used to record the individual electromagnetic readings. Both the in-phase and quadrature components of the electromagnetic field will be measured and recorded. Readings will be measured both parallel and at 90^{o} to the transect line if the orientation of anomalies is required. These data will in turn be stored on a computer and printed out at the end of each field day. For each site where EM-31 survey is to be conducted, a calibration area, free of cultural interference, will be established. The EM-31 response will be measured at this area at the start of each day. This check will be made every 2-3 hours throughout the survey to insure that no significant meter drift is occurring during each survey.

16.3.3.1.2 Data Interpretation

Upon completion of each electromagnetic survey, the data will be presented in both profile and contour form. Both the in-phase and quadrature components will be plotted. This multiple presentation format will aid in the interpretation of the data. All of these presentation aids will be interpreted to identify the locations of buried metallic objects, disposal pits, waste boundaries, and areas of elevated subsurface soil apparent conductivities. These data will be compared to the results of the GPR surveys to provide as complete and accurate interpretation of the subsurface conditions at each SWMU as possible.

16.3.3.1.3 Data Verification

The EM-31 instrument is calibrated by the manufacturer. This calibration can be rechecked in the field but this requires that access to highly resistive rock outcrops are available. A secondary field calibration is performed on a daily basis to insure repeatability of measurements and to check against

daily meter drift. This field calibration is the only performance evaluation that is performed on these instruments.

16.3.3.2 Electromagnetic (EM-61) Survey

Electromagnetic-61 surveys may be conducted with the Geonics EM-61 High-Sensitivity Metal Detector at the Depot. The objective of the EM-61 surveys is to identify the location and depth of buried metallic objects, including UXO, utility lines, underground storage tanks, and waste disposal pits. The unit is capable of detecting a single drum at a depth of about 10 feet. The EM-61 utilizes time-domain electromagnetic principles to provide higher resolution and rejection noise than the frequency-domain EM-31. However, the EM-61 is not well-suited to map shallow groundwater contamination or changes in surficial geologic materials.

16.3.3.2.1 EM-61 Survey Procedures

1. Grids will first be established and the corners of each EM-61 grid will be established by a registered NY State land surveyor. Additional temporary markers or flags will be placed for control within the grid.

2. Grids will be surveyed by the EM technique using Geonics EM-61 TDMD instruments. Parsons personnel will conduct these surveys. The device consists of a one-meter square transmitter/receiver frame, an electronics backpack, and a hand-held data logger. The frame houses two coaxial coils: one 40 cm above the other. EM-61 devices generate electromagnetic pulses that trigger eddy currents in the subsurface. The eddy current decay produces a secondary magnetic field that is monitored by two receiving coils and recorded by an attached data logger. For the most part, the EM-61 instrument will be used in a wheeled mode. The survey can be conducted by driving the cart over the targeted area. In this case, the survey will require two operators on board during data acquisition, which consists of one driver and a passenger to assist with navigation and monitor incoming data on the laptop. Alternatively, in rough terrain, the wheels are removed and the transmitter/receiver frame may be carried by the operator. A second individual will record the progress of the survey as well as any surface features that might affect the response of the instrument. Detailed record keeping will facilitate the discrimination of surface and subsurface objects. This person will also place survey markers to allow the EM-61 operator to maintain accurate profile lines.

3. EM-61 data will be collected along parallel survey lines spaced 3 feet apart in all grids with dimensions of 100 ft by 100 ft. Review of the Geophysical Prove-out Report data indicated that a survey line spacing of three feet is required to detect OE the size of an MKII grenade or smaller. Prove-out results also show that OE the size of a 155mm shell buried four feet below the ground

surface will be detected up to four feet away from the center of the EM-61 sensors. If larger lane spacing than those stated above are believed to be warranted for a particular area, the justifications for such changes will be provided to the Parsons project manager and USACE. Any such changes will be considered on a case by case basis, and will be approved by the Geophysical Coordinator, the Parsons project manager, and USACE prior to implementation in the field. Discrete measurements are taken every 8 inches along the profile lines. Measurements are automatically triggered by the survey wheel and stored in the data logger. The voltages (mV) induced in both receiver coils are recorded at each station.

4. Grids surveyed manually, using the EM-61 in the single unit configuration, will be subdivided into parallel survey lanes. During the EM-61 survey, the survey lines are traversed over a known distance with data being collected incrementally with distance. EM measurement events are triggered each time the instrument's tire rotates a specified distance. Data markers (fiducial marks) can also be inserted manually by the operator. Review of the Geophysical Prove-out Report data indicate that only a single fiducial mark will be needed at every 50 feet of each manually surveyed line to meet the lateral positioning accuracy goal of ±1 foot established for this project.

5. Data corrections for data collected manually will be performed using information recorded in the field log books (start and end of line stations, line spacing, fiducial mark intervals, etc.), information digitally recorded in each EM-61 data file, and the geodetic survey coordinates of the grid corners. This operation involves correcting the EM-61 data that was collected incrementally with distance to either compress or expand the recorded measurement locations for each line so that they cover the actual distance traveled. This operation is required to compensate for variations in the terrain along the survey line, which affects the rotation of the instrument's wheels. The survey data are then rotated and translated from the local coordinate system they were collected in (where the southwest corner of the grid surveyed was assigned a coordinate of 0E, 0N) to the New York State Plane coordinate system.

6. A "meandering path" geophysical survey will be conducted in areas where grids cannot be cleared by randomly traversing investigation areas using EM-61 units in conjunction with Trimble® 4800 GPS units. The EM-61 and 4800 instruments will be set up and checked following the procedures in the provided instruction manuals. The EM-61 unit will be manually towed by one of two individuals comprising the geophysical survey team. Each team will be assigned a UXO escort to provide visual OE clearance of the transect path and brush cutting as necessary. The lengths and locations of these transects may change depending on field conditions. The area covered by a transect will be calculated as the distance traveled multiplied by the width of the EM-61 footprint (one meter).

7. The Pathfinder™ software (provided by Trimble®) will be used to determine times of the day during which the correct number and position of satellites cannot be obtained. The daily work schedule of download and survey times will be appropriately adjusted to account for these times.

8. During the surveys, the EM-61 will collect EM data while the GPS records the location of the data collection points. EM-61 data will be time-stamped and combined with the GPS positioning data. If GPS lock is lost during the geophysical survey, an audible signal notifies the geophysicist of the condition. If the signal is not reacquired within a few seconds the survey is temporarily halted until the signal is again locked. In addition, the geophysicist may opt to begin walking a straight line segment at constant pace upon indication of loss of GPS lock so equipment position can be reconstructed by a time average across the distance lost until GPS lock is again obtained. As a worst case, very small data segments in the transect may be lost. This very small data loss is inconsequential as the transects are typically lengthened during the survey in anticipation of this minor loss. If the lost signal is not reacquired within a few minutes, the geophysicist may move a distance away from the last survey location and recommence survey at a new location, thus breaking the transect into smaller pieces.

16.3.3.2.2 Data Interpretation

Upon completion of each EM-61 survey, the data will be presented in both profile and contour form as a check of data quality and completeness. After correcting for bias or offset in each data set, the response from the lower coils will be presented as color contour maps to facilitate interpretation. The difference in the response of the upper and lower coils may be used to estimate the depth of each anomaly. The EM-61 data will be compared to the results of other geophysical surveys to provide a comprehensive interpretation of subsurface conditions.

16.3.3.2.3 Data Verification

The EM-61 is calibrated by the manufacturer. There is no means or necessity to calibrate the instrument in the field. The functionality of each instrument is tested daily by passing the EM-61 over a known metallic object and noting the response. The background response of the EM61 may vary slightly from day to day or from instrument to instrument. However, post-processing of the data removes this bias. Interpretation of EM-61 data requires only the relative response of each receiver coil.

16.3.3.3 Ground Penetrating Radar Survey

A GPR survey of selected areas within the depot may be conducted to locate buried structures (i.e., buried or filled-in pits, trenches, disposal areas) and obtain more information on anomalies detected during the electromagnetic surveys. GPR can also identify the original ground surface beneath berms.

16.3.3.3.1 GPR Survey Procedures

The GPR instrument will be hand operated on the identified areas. As the equipment is pulled across the site, the reflected radar pulses are transmitted to the receiver unit where they are converted to analog signals. The analog signal is transmitted to the control unit where the signal is electronically processed and sent to the graphic recorder. The graphic recorder produces a continuous chart display on electro-sensitive paper. This real-time display enables the operator to interpret the data on site.

16.3.3.3.2 Data Verification

Data from the GPR survey will be verified when subsurface explorations are performed to identify anomalies and penetrate through disposal pits.

16.3.3.4 Exploration of Subsurface Geophysical Anomalies

Exploration of subsurface geophysical anomalies will be performed to verify the data obtained during the GPR and electromagnetic surveys.

The excavations will be performed using a backhoe with a smooth-edged bucket. The excavation will extend to a distance of five feet on either side of the subsurface anomaly. The width, length, and depth will be based on the size of the geophysical anomaly with applicable considerations for prevailing conditions such as flooding or stability of the excavation. Based on consultation with the project manager and field team leader, the final depth of excavation will be decided. The boom and bucket of the backhoe will be operated in such a manner as to not exert impact or shock to the soil or its contents. The depth of the excavation increment (not to exceed two feet) will be at the discretion of the UXO Safety Officer. The contents of each bucket of material removed from the excavation will be gently placed on the ground and spread out to expose the contents as much as possible for a visual inspection. If at any time during the excavation, the UXO Safety Officer determines the risks and hazards are too great to proceed with the excavation, the excavation will be halted.

The excavation will be continuously monitored with a PID or organic vapor monitor (OVM). At no time will any personnel be permitted to enter the excavation. If the pit is not closed immediately after any samples have been obtained, the excavation will be barricaded to prevent accidental entry by

personnel working on the site. Each excavation will be marked after closure as needed for identification of the site.

A log containing the location of each excavation will be maintained by the field team. The log will include the excavation number, location, items observed (such as UXOs or drums), and other significant data. Records pertaining to sampling, geological data and associated requirements will be maintained by the project geologist.

Sites that potentially contain UXOs will be investigated by a UXO technician with the aid of UXO Safety Officer and UXO Project Leader. Due to the potential hazards associated with the excavations, when necessary, the UXO contractor will obtain samples for the project geologist in accordance with the sample collection procedures described in Section 16.4. The excavation equipment will be cleaned between excavation sampling operations in accordance with decontamination procedures outlined in Section 16.3.11.

16.3.3.5 Geophysical Survey Methods-Magnetics

In the case of grids placed in areas where the maneuverability of the EM-61 instruments is too limited to enable accurate data positioning or in areas where identification of a number of anomalies suggests using another method to improve anomaly picking, a Geometrics G-858 magnetometer (or equivalent) may be used for the surveys, except in areas where slap flares are expected. The G-858 instrument uses a cesium vapor magnetometer sensor incorporating a miniature atomic absorption unit from which a signal proportional to the intensity of the ambient magnetic field is derived (Pawlowski, et. al., 1995). The sensitivity of the instrument ranges from 0.05 nanoTesla (nT) at a data recording rate of 10 Hz to 0.01 nT at a data collection rate of 1 Hz. An operational manual of the G-858 is attached in Appendix G.

Data collected with a G-858 will use the same procedures for grid preparation and data processing as those for the manually-towed, single unit EM-61 configuration described above. The G-858 is carried by the operator above the ground, while the EM-61 is rolled along it. In addition, it requires less than two feet of lateral space while the EM-61 requires three. This means that the G-858 can sometimes be used in areas where the EM-61 cannot, especially in wooded or hilly areas. The vertical separation of the coils will be set at 1.5 feet for all surveys. For the most part, it is expected that bottom sensor data will be used to make target picks. However, gradient or top sensor data may be used in regions where large ordnance is expected, as either may exhibit less noise than the bottom sensor in high clutter areas. The magnetic technique will also be applied using Schoenstedt™ GA-52CX or White's, which also detect non-ferrous metals, magnetometers to pinpoint the exact locations of anomalies as part of the intrusive investigation for hilly or very heavily wooded areas. Size and orientation of buried targets and the soil characteristics of the work area limit the depth of detection of either of these magnetometers.

Neither instrument is not capable of classifying the anomaly; each will only show the presence or absence of a magnetic field.

16.3.3.6 Geophysical Survey Instrument and Equipment Maintenance and Inspection

Testing Procedures and Frequency

Instruments and equipment used to gather and generate environmental data will be tested with sufficient frequency and in such a manner that accuracy and reproducibility of results are consistent with the manufacturer's specifications.

Hand-Held Metal-Detector QC

At least twice daily, all of the hand-held metal-detectors (White's, Schonstedt™) will be function checked at a test grid to be established at the beginning of the project. The checks will be performed by measuring the instrument response over locations of items in this test grid and comparing that response to the standard response of each instrument. The seed items in the test grid will be inert or simulated items representing an M-9 grenade buried at 2 feet and a 155 mm shell buried at 4 feet. In addition, a slap flare, a 40 mm grenade, and a fuze (or reasonable simulants) will be seeded at depths to be chosen as representative of those expected at the areas of concern. The ability of the metal-detector to detect the items is the only pass/fail criteria in this QC check. If the instrument cannot detect all of the items, it will be removed from service.

EM-61 and G858 Daily QC

Prior to beginning grid surveys, a baseline spike reading will be determined for both the EM-61 and the G858. Each instrument will be used to collect 10 survey lines over a metal spike placed in the ground. The range between the minimum and maximum readings for each line will be averaged to determine the baseline reading for each instrument. During each subsequent day of use, the EM-61 and G858 magnetometer will be tested before and after the survey of each grid block. A metal spike will be placed in the ground adjacent to each of the grids, and one survey line will be collected over this spike before and after the survey of the corresponding grid. The instrument response over the spike will be recorded on a survey sheet, and the highest readings for each line will be compared to the baseline spike value for the corresponding instrument to ensure that the instrument response is consistent. Peak readings within 20% of the baseline reading will be regarded as consistent for the purposes of QC.

A static test of the EM-61 and the G858 will be performed each morning in order to detect any drift occurring in the instrument's response over a short time period. Cables will be shaken to test for shorts, and loose cables will be taped to the appropriate sensor frame. Each instrument will be set to collect

data continuously for three minutes (4 readings a second for the EM-61 and 10 readings a second for the 858) over one location. Afterwards, a small metallic test object will be placed on the same location in a standard orientation, centered beneath the instrument sensors, and the static test will be repeated. For this project, a metal spike (or an inert M69 if possible) will be used as the test object. If the response of the instrument varies on either test by more than ±3mV of the initial response for the EM-61 or ±3nT on the gradient scale for the G858, the instrument will be repaired or removed from service. Data will be graphed and examined for compliance with the required QC guideline and documented in a daily field logbook.

In the case of the G858, a file will also be collected each day in order to correct any heading errors associated with the collection of magnetic data. This file will consist of a continuous measurement of one point. The operator will hold the magnetometer sensors over this location and turn in a 360° circle around the location. As the operator turns through each point of the compass (N, S, E, and W) a mark will be made in the data. Any variation in the magnetic field strength identified in this file will be attributed to the direction that the operator was facing at the time and will be processed out of the final data set.

Finally, one line of each grid block collected, typically the first line, will be repeated after collection of the grid. For each grid, the QC line will be collected first, a new file will be established to collect the remainder of the grid, and a third file will be used to re-collect the QC line upon completion of the grid. The QC lines will then be graphed and compared to ensure that they overlay each other.

EM-61 and G858 Weekly QC

Once a week, a more detailed QC check will be performed on each of the instruments. For this QC, a 100-foot long line will be established near the site trailer. For each instrument, six survey profiles will be collected along this line. The six profiles will be collected as follows:

1. Profile 1 will be run approximately N or E with no added anomalies along the line,
2. Profile 2 will run the opposite direction with no added anomalies along the line,
3. Profile 3 will run N or E with a spike added at the 50’ mark along the line
4. Profile 4 will run the opposite direction with the added spike on the line
5. Profile 5 will run N or E at a very fast pace with the added spike on the line
6. Profile 6 will run the opposite direction at a very slow pace with the added spike on the line

Background repeatability will be established by a comparison of the first two profiles, anomaly repeatability will be established by a comparison of profiles 3 and 4, and proof of acquisition speed insensitivity will be established by a comparison of profiles 5 and 6. For QC, the first two lines should

match each other to within ±3mV for the EM-61 or ±3nT on the gradient scale for the magnetometer, and the peaks on the anomaly-included profiles should be within 20% of each other.

GPS QC

For the purposes of grid location and anomaly reacquisition, the GPS equipment will be tested at known survey monuments. A GPS point will be collected at an established survey monument at the beginning and end of each day. Stations measured to within 0.5 feet of the known location of the survey point will be deemed accurate for the purposes of this project. For meandering path QC, two spikes will be placed in the ground in the vicinity of an existing survey monument. When geophysical data is to be collected in the meandering path mode, the GPS will be used in conjunction with the EM-61, and a line of data will be collected over these two points and the survey monument to ensure that meandering path data can be used to correctly locate anomalies. These three points will remain constant throughout the project. A "lag bar" or similar piece of metal will used in all meandering path surveys to post-process and locate the data correctly. All of the QC data collected during the project will be submitted with the survey data collected on the corresponding day. In the case of meandering path QC data, both raw and corrected ASCII files will be submitted. Any processing or filtering of the data will be detailed in a readme.txt file sent with the data.

Testing, repair, or replacement records will be filed and maintained by the Geophysical Survey Team Leader and Intrusive Investigation Field Supervisor and may be subject to audit by the QA Manager. Testing records of the field instrumentation will be filed with the Parsons project manager in Boston after the field work is completed.

Field Instruments

All geophysical survey instruments will be function checked twice daily as described above. The operational and test procedures will conform to manufacturer's standard instructions. This field test will ensure that the equipment is functioning within the allowable tolerances established by this project.

16.3.4 Soil Boring Advancement

Soil boring procedures will be performed following industry standards. Unless otherwise directed by the project manager, the borings will be advanced to "refusal" which will represent the depth of the "competent" bedrock. Auger "refusal" in "competent" shale will be defined as the depth (after penetrating the weathered shale) when augering becomes significantly more difficult and auger advancement is slow.

16.3.4.1 Equipment

- Drilling rig capable to drilling to the appropriate depth for the well
- 4 1/4-inch or 6 1/4-inch I.D. hollow stem augers (HSA)
- Split Spoon Samples: 2-inch and 3-inch, 2-foot-long carbon steel split spoons
- FID or PID (e.g., OVM)
- Folding ruler
- Field table
- Tin foil
- Ball jars with lids
- Field book
- Boring log field forms
- Laboratory sample containers
- Coolers
- Ice
- Stainless steel spatula
- Stainless steel sample bowls
- 55-gallon drum for soil
- Decontamination equipment as described in Section 16.3.11.
- Level D health and safety equipment as described in the Generic Site-Wide Health and Safety Plan.

16.3.4.2 Field Procedures

1. Pre-drilling check as described in Section 16.3.2.

2. Inspect all drilling equipment.

3. Decontaminate all drilling equipment (e.g., rig, water tank, casing, augers, rods, tubs, tools, etc.) as per Section 16.3.11 prior to starting the work. Inspect all equipment to assure that residual oils, asphalt, grease, grout, soil, etc. has been removed.

4. Go to the boring location and use hollow stem augers method to initiate the boring. Where site conditions (e.g., fine sand running up into the augers) prevent the use of augers, soil borings may be advanced using the drive and wash technique, with the approval of the project manager.

5. Any water used during drilling will be clean potable water that has undergone water quality analyses. The amount of water used will be kept to a minimum, with the estimated amounts used on any boring recorded on the boring logs. **No other drilling additives shall be used**.

6. Alternative drilling methods may be allowed when approved in writing by the Parsons project manager, the Army, or the Regulatory Agency.

7. Use of lubricants is subject to the approval of the Parsons project manager, or the field team leader. If lubricants are used on down-hole equipment they must be non-petroleum based products. Material Safety Data Sheet (MSDS) describing the product must be provided to Parsons project manager in advance of use. In addition, Parsons may require that a comprehensive chemical analysis of the lubricant be completed prior to use.

8. Care will be taken to avoid contact between downhole drilling equipment and those parts of the rig where petroleum based lubricants are used (i.e., motors, hydraulic lines and pimps, transmissions, gearboxes, etc.).

9. Boreholes will be advanced to a predetermined depth or refusal. For temporary well installations, advance the boring to a point immediately above the targeted sample interval (i.e., screened interval). The final depth of the borehole will be verified by the field crew.

10. Split-spoon refusal is defined as the point where 100 or more blows of the hammer fails to advance the split spoon sampler more than 6 inches.

11. During drilling, soil spoils will be continuously monitored for volatile organic compounds. Monitoring specifications are described in the Generic Site-Wide Health and Safety Plan.

12. Spoil materials will be removed from the vicinity of the borehole mouth periodically throughout drilling. Spoils associated with grouting operations will be handled as a waste stream.

13. Mark the boring with a stake or flagging so that it's location can be surveyed and label the stake or flagging with the boring number.

14. Samples shall be collected in accordance with procedures outlined in Section 16.4.

15. After the boring is completed, and if a well is not to be installed, it shall be refilled to the ground surface with lean grout containing at least 3% bentonite powder by volume. The cement/bentonite grout seal shall be placed from the bottom of the boring to approximately 3 feet below ground surface by pouring the mixture into the hole. The grout mixture shall consist of Portland cement (ASTM C 150-86) and water in the proportion of not more than 7.0 to 8.0 gallons (gal) of clean water per bag of cement [1 cubic foot (ft^3) or 94 pounds (lb)]. Additionally, 3 percent by weight of bentonite powder will be added to help reduce shrinkage of the grout mixture. The grout will be

allowed to set for a minimum of 48 hours. If the borehole is greater than 15 feet and groundwater is present in the borehole, the grout will be pumped through a tremie pipe to the bottom of the boring. Grout will be pumped in until undiluted grout discharges from the bore hole at the ground surface. A bentonite backfill consisting of bentonite pellets will be placed from the top of the cement/bentonite grout seal to the ground surface and allowed to hydrate.

16.3.5 Groundwater Monitoring Well Installation

This section presents installation SOPs for unconsolidated groundwater monitoring wells and bedrock groundwater monitoring wells.

16.3.5.1 Unconsolidated Groundwater Monitoring Wells

Proper design, construction, and installation of the proposed monitoring wells are essential for accurate interpretation of the groundwater data. The program to be implemented is consistent with the USEPA Region 2 CERCLA QA Manual and the NYSDEC TAGMS regarding design, installation, development and collection of groundwater samples. Further, the program is in compliance with all requirements described in the NYSDEC, 6 New York State Codes, rules and Regulations (NYCRR) Part 360, Solid Waste Management Facilities Regulations, Section 360-2.11, which details groundwater monitoring well requirements. All details of the well completion activities will be recorded on the Overburden Monitoring Well Completion Report & Installation Detail form (Appendix C).

16.3.5.1.1 Equipment

- A 4 1/4-inch or 6 1/4-inch hollow-stem auger
- 4-inch, 6-inch, or 8-inch diameter, Schedule 40 or 80 polyvinyl chloride (PVC), threaded, flush jointed, PVC wire-wrapped well screen (5 and 10 foot lengths) of appropriate slot size (expected screen slot size of 0.010"), riser pipe, threaded end cap, and expansion plug for top of riser.
- Portland cement
- Powdered bentonite
- Filter sand pack
- Fine filter sand (No. 00)
- Bentonite chips, preferably Enviroplug brand
- Protective casing or a roadway box, as directed.
- Metal stamps to label casing and roadway boxes.
- Potable water
- Tremie pipes for sand, seal, and grout
- Overburden Monitoring Well Completion Report & Installation Detail form (Appendix C)

16.3.5.1.2 Procedure

1. Overburden borings will be advanced as described in the Section 16.3.4.

2. Equipment decontamination as described in Section 16.3.11. All equipment must be steam cleaned between holes. Where possible, upgradient wells should be drilled first. Water used during drilling or well installation will be clean potable water that has undergone water quality analysis. Estimated amounts of water used will be recorded on the appropriate forms.

3. Installation of overburden monitoring wells will begin as soon as possible following the completion of the boring. Once installation of the well has begun, the installation process must be continuous until the well has been grouted and all augers or casing removed. Only one well will be installed in each boring. Installation will begin within 48 hours for fully cased boreholes. Once installation has begun, no breaks in the installation process will be made until the well has been grouted and the drill casing removed. In some instances installation of well clusters (i.e., overburden and bedrock wells) may be required. The number of wells at a sampling location will depend on the heterogeneity and simplicity of the geology, the physical/chemical properties of the contaminants, and the location of the suspected sources of pollutants.

4. If well installation does not begin immediately after borehole completion, steps must be taken to insure the integrity of the borehole. Such steps include securing the top of the drill pipe to avoid downhole contamination and to prevent vandalism (e.g. cap and block the hole using the drill head, alternatively block access to the outside of the drill pipe using a drum and blocking it with the drill head).

5. Depending on stratigraphic conditions, all boreholes should be over drilled by a distance of 0.5 feet to 1 feet to allow for the installation of a sand cushion at the base of the well's screened length. The amount of over drilling must be confirmed by the field team leader prior to installation of the well.

6. When using drive-and-wash or other drilling methods requiring water, the casing must be flushed prior to well installation to remove residual overburden material.

7. The Parsons field crew will measure, or observe the driller measure, the depth to the bottom of the borehole. Confirm that the depth is sufficient to proceed with well installation or direct that additional drilling be conducted to reach the required depth. Record the bottom of boring depth on the Installation form prior to proceeding with the well installation.

8. The project manager or field team leader will define the well screen length, slot size, and type of surface completion required for the well installation. Wells will generally be screened from 3 feet above the water table to the top of competent bedrock.

9. Verify and record the actual length and slot size of the well screen and the effective length of the point of well plug or cap that will be used to construct the well prior to beginning the installation.

10. All PVC well materials must be new, clean and in the manufacturer's wrapping. Check the condition of each piece before it is placed in the hole. Any well component that is not found to be visually clean and free of soil or grease will either be decontaminated prior to use or replaced. Decontamination will consist of steam cleaning as defined in the SOPs, and if steam cleaning does not remove contamination, the well materials will be replaced.

11. Verify that materials at the drill site are the correct size or brand and present in sufficient quantity to complete the installation without interruption. If necessary materials are lacking, postpone installation of the well until required material is present. Essential materials include well screen, riser, well point, expansion plug, filter sand, bentonite chips, bentonite powder, and Portland cement.

12. Thread the well point plug or cap onto the screen. At the well head carefully lower the well assembly (screen/well point first) into the borehole, attaching additional sections as the well is lowered into the hole. Make sure that all threaded connections are "hand-tight" and sealed before lowering a section into the hole. Record the number of pieces placed in the hole to cross-check the well depth. Do not use tools to tighten PVC joints. This will help to avoid breakage and contamination.

13. On deep wells, it may be necessary to use clamps to hold the PVC while assembling the joints. Exercise the greatest amount of caution to ensure that the well assembly is not dropped.

14. Once the well assembly has reached the bottom of the borehole, install the expansion plug in the top of the PVC to avoid dropping anything in the well. Raise the PVC assembly 0.1 to 0.3 feet off the bottom of the borehole. Using a clamp, hang and center the PVC well assembly in the center of the drill pipe.

15. Calculate the approximate volume of filter sand required to fill the annular space between the 4 inch PVC and the 8 to 12 inch HSA borehole.

16. Carefully pour a volume of sand equivalent to 1 to 2 feet of borehole annular space into the hole. Allow it to settle. (On deeper wells with greater than 50 feet of water present, the time necessary for the sand to settle may exceed 15 minutes.)

17. Slowly raise the PVC well assembly 0.1 to 0.3 ft to the required depth to provide a sand cushion at the well point. NEVER PUSH DOWN ON THE WELL ASSEMBLY.

18. Slowly add filter sand in 1 to 3 foot increments while slowly raising and removing the augers or casing. Monitor the sand level to ensure that clean filter sand is always inside the augers or the casing and to confirm the sand has not bridged. To avoid bridging of the sand pack on deeper wells it may be necessary to tremie the sand into place, using clean potable water, recording the amount of water used on the well completion form. Be careful not to pull the well up or let it drop while pulling the augers or casing.

19. Following the addition of the sand, the PVC well assembly will be raised an additional 0.1 to 0.5 ft to provide a sand cushion at the well point. Repeat step 18 until the filter sand is 2 feet or 20% of the screen length (whichever is greater) above the top of the screen. The filter sand should be six inches below the bottom of the screen length. The sand thickness above the screen may have to be reduced to less than 1.0 foot on near surface wells to allow proper surface completions. If possible, install a 1 to 2 foot layer of finer sand on top of the filter sand (total sand thickness above the screen should not exceed 6 feet). Confirm any modifications with the Site Manager before proceeding.

20. A finer grained sand pack material (100 percent passing the No. 30 sieve and less than two percent passing the No. 200 sieve) six inches thick must be placed at the top of the sand pack between the sand and the bentonite seal. The fine sand will serve as a barrier between the filter sand pack and the bentonite seal to prevent infiltration of the bentonite into the sand pack around the well screen.

21. Add bentonite chips to create the seal above the sandpack. Incrementally add medium sized bentonite chips (e.g., Enviroplug Brand) to the well. Repeatedly monitor the level of the top of the chips to avoid bridging of the seal between the PVC and drill pipe. The final bentonite seal should be at least 3 feet thick on shallow wells and up to 5 feet thick on deeper wells. Modifications recommended and approved by the field team leader may be necessary for near surface wells. Add 15 gallons of potable water to the borehole if the bentonite seal has been placed above the water table.

22. A 6 to 12 inch fine grained sand pack must be placed above the bentonite seal to minimize grout infiltration.

23. Pull casing or augers up to within a foot of the top of the bentonite seal fine sand (#00) pack. Allow approximately 1 hour for the bentonite chips to hydrate or the bentonite slurry to settle. During this time, prepare for grouting the hole.

24. Grout the annular space around the riser, above the bentonite seal fine sand (#00) pack, to a final level that is 3 to 5 feet below the ground surface using 3% by weight bentonite to cement. The grout mixture will consist of bentonite powder and water and will be an New Jersey Depart of Environmental Protection-approved grout. This mixture must be thoroughly mixed to minimize the possibility that the bentonite will lump. All grout seals installed below the water table must be tremied into place, with the tremie tube placed 2 to 5 feet above the top of the bentonite seal fine sand (#00) pack. As the grout is pumped in, the tremie pipe and augers or casing are withdrawn. Grouting will be done in one continuous operation, from the top of fine sand layer to the depth at which the cement collar is to be placed (about 3-5 feet below grade). Installed grout seals will be allowed to settle and set-up for 24 hours prior to being inspected. Additional grout will be added to bring the grout level to a final height between 2 to 3 feet below the ground surface for surface well completion. Record all details of the well completion activities on the proper attached Well Completion form.

25. Complete the concrete surface collar and surface completion two to seven days after installing the well.

26. Prior to well development, at least 48 hours will have elapsed after the well is grouted. This allows the grout to harden. The well will be developed at least seven days before groundwater monitoring activities or groundwater sampling to allow the groundwater to stabilize.

27. Spoils associated with grouting operations will be handled as a waste stream.

16.3.5.2 Bedrock Groundwater Monitoring Wells

Bedrock well installation will be identical to the unconsolidated well installation with the exception of the bedrock coring procedures and installation of a steel casing across the bedrock/overburden boundary.

After initial drill refusal at the top of bedrock, the hole will be drilled or reamed 3 to 4 feet into competent bedrock to confirm the bedrock surface and allow for the installation of the outer steel casing into the competent bedrock. Following the initial coring into bedrock, approximately 2 feet of bentonite chips will be added to the bottom of the borehole and allowed to hydrate for 15 minutes. The steam-cleaned steel casing will be advanced to 2 feet above the bentonite seal, and grout will be tremied into the hole until undiluted grout flows from the top of the hole. The casing will be pushed into the

bentonite seal. If the grout level drops during this operation, more will be added to the hole until the level stabilizes 3 feet below the ground surface.

The grouted casing will be allowed to set for a period of 48 hours prior to the initiation of coring operations, after which the boring will be advanced to a maximum depth of 20 feet below the steel casing using an HQ-size core (2.5 inches diameter) and core barrel. During coring, a potable analyte-free water will be pumped into the borehole to serve as a lubricant and to remove the fine rock flour and shale chips from the hole. The water will be recirculated into the hole after passing through a steel bath with several baffles to contain most of the rock flour and shale chips, preventing them from being reintroduced into the borehole. A description of the rock core will be recorded on the Core Boring Report according to the procedures outlined in Section 16.3.1.2, and the well completion will be detailed on the Bedrock Monitoring Well Completion Report & Installation Detail form. Both forms are contained in Appendix C.

16.3.6 Groundwater Monitoring Well Development

All installed groundwater monitoring wells require development prior to sampling. Groundwater monitoring well development will be performed to remove sediment from inside the well casing and to flush fine materials from the portion of the formation adjacent to the screen. Groundwater monitoring wells should be developed at least seven days before groundwater monitoring activities or groundwater sampling to allow the groundwater to stabilize.

16.3.6.1 Equipment

- Submersible pump, hand pump, staged submersible pump, peristaltic, or other suitable pump
- Bottom filling bailer
- Stopwatch or watch
- pH meter
- Specific conductivity meter
- Nephelometer (field portable turbidity meter)
- Thermometer
- Battery operated water level indicator
- Surge block
- Health and safety equipment as necessary
- Large funnel
- Well Development Report form (Appendix C)
- 55-gallon drum for soil
- decontamination equipment as described in Section 16.3.11

- Level D health and safety equipment as described in the Generic Site-Wide Health and Safety Plan (Parsons, 2005).

16.3.6.2 Field Procedures

1. Well development must not begin any sooner than 48 hours after the well is grouted. All data and calculations must be recorded on the attached Well Development Report form (Appendix C). Development records will include:

    - Groundwater monitoring well number;
    - Date and time of development;
    - Development method;
    - Predevelopment water level and well depth;
    - Volume of water produced;
    - Description of water produced; and
    - Post development water level and well depth.

2. Measure the groundwater elevation and well depth. Compare data to original (i.e., installed) well depth.

3. Calculate the standing water volume in the well as described on the Well Development Report form. Take into account the water standing in the riser pipe and screen as well as the water contained in the sand-pack surrounding the screen, assuming a 30 percent (%) porosity for the sand-pack.

4. Following the groundwater elevation measurement and calculations, determine the percentage of the screen covered with silt in the well by measuring the depth to the top of the silt in the well, if any is present. Determine the thickness of silt above the bottom of the screen, if present, and calculate the percentage. If the percentage is greater than 10%, remove the silt at the start of purging by lowering the intake to the bottom of the well. Once the silt has been removed, lift the pump intake to the top of the water column and continue purging.

5. In addition, remove all fines that may have accumulated within the well, as well as those that may have been smeared on the inside of the borehole during well drilling.

6. Remove 5 times the calculated standing water volume from the well (as well as any water lost to the formation during drilling) using a submersible, hand, staged submersible, peristaltic, or other suitable pump as approved by the Site Manager. The pump selection will be made based on saturated thickness, depth to water, and rate of recovery. At the completion of the third, fourth, and

fifth volume, measure the pH, specific conductivity, and the turbidity of the water. A non-turbid discharge (e.g., NTU less than 50) is sufficient to measure NAPL thickness, water level, etc. However, a "turbidity-free" discharge is required for wells used to measure groundwater quality. As a general rule these readings should be reproducible to $\pm$ 0.2 standard units for pH, 10% for specific conductivity, and $\pm$ 10 NTUs for turbidity, when the well development is complete. However, this is not a requirement.

7. If consecutive water quality measurements do not agree to the limits defined in Step 5, additional standing water volumes must be removed until the discharge meets the "turbid-free" requirement.

8. If 10 standing volumes of well water have been removed and the above criteria have not been met, compare the amount of water removed to the amount of water lost to the formation during drilling. Development will continue until either stable water quality measurements are obtained or development has removed one well volume of water in excess of the amount of water lost to the formation during drilling. At this time the well will be declared developed. The utility of wells that do not meet the development requirements must be accessed whenever samples for chemical analysis are collected.

9. When slow recoveries hamper well development operations (i.e., well is pumped dry after the removal of less than required volumes), measure the water quality parameters on the last water removed during each separate development session. If development criteria are not met within 96 hours of beginning well development, well development will continue until more water has been removed than was lost to the formation or the well has been pumped to dryness and allowed to recover five times within a seven day period from initiating well development operations. At this time the well will be declared developed. The utility of wells that do not meet the development requirements must be accessed whenever samples for chemical analysis are collected.

10. The pumped development water will be managed and disposed in accordance with the Section 16.3.12.

16.3.7 Groundwater Monitoring Well Abandonment

Groundwater monitoring wells developed during the site investigation/remediation may be abandoned for various reasons (e.g., normal completion of site activities). All abandonment of monitor wells shall be performed in accordance with federal, state, and local laws and regulations. Details of all abandonment procedures will be fully documented by photographs, depth and volume measurements, any calculations, and pertinent notes.

16.3.7.1 Equipment

- Drilling rig capable to drilling to the appropriate depth for the well
- Field monitoring and screening instrumentation
- Mud-pump
- Decontamination equipment.
- Spoils handling equipment.
- Grouting supplies (powdered bentonite, Portland cement, and water).
- Tremie pipe
- 55-gallon drum for soil
- Decontamination equipment as described in Section 16.3.11 and
- Level D health and safety equipment as described in the Generic Site-Wide Health and Safety Plan (Parsons, 2005).

16.3.7.2 Field Procedures

The procedures for the abandonment of boreholes are as follows:

1. The well should be cleared of all obstructions prior to abandonment. Obstructions such as pumps, pipes, wiring, and air lines must be pulled. An attempt should be made to pull the casing when it will not jeopardize the integrity of the borehole. Before the casing is pulled, the well should be grouted to near the bottom of the casing. This will provide a seal if the well collapses after the casing is pulled.

2. Prepare a sufficient quantity of an appropriate grout mixture to fill the hole to within 4 feet of surface grade. If more or less grout mixture than this is required, maintain the same material ratios for all additional material. The grout mixture shall consist of Portland cement (ASTM C 150-86) and water in the proportion of not more than 7.0 to 8.0 gallons of clean water per bag of cement [1 cubic foot or 94 pounds]. Additionally, 3 percent by weight of bentonite powder will be added to help reduce shrinkage of the grout mixture. The grout will be allowed to set for a minimum of 48 hours. Potable water must be used when mixing grouting materials. The amount of water used will be recorded in the field notes of abandonment procedures. If slurry is used to seal the well, a mud balance and/or Marsh Funnel shall be used to ensure that the density (lbs/gal) of the abandonment mud mixture conforms to the manufacturer's specification.

3. Pump the grout mixture into the borehole through a tremie pipe in one continuous operation, from the bottom to the top of the borehole, while removing all drilling equipment (augers, casing, etc.) from the borehole. The tremie/grout pipe may be slowly raised as the grout is being placed but the

discharge end of the pipe shall remain submerged in the grout at all times until grouting is complete.

4. When grouting a borehole, the grout must extent up to the ground surface. Then, allow the grout to settle and regrout as necessary.

5. All abandoned monitor wells shall be checked 24 to 48 hours after mud/solid bentonite emplacement to determine whether curing is occurring properly. More specific curing requirements or quality assurance checks may be recommended by the manufacturer and shall be followed. Additionally, if significant settling has occurred, a sufficient amount of mud/solid bentonite shall be added to attain the initial level. These slurry/solid bentonite curing checks and any addition of mud/solid bentonite shall be recorded in the field logs.

6. The driller must maintain an accurate written log of all materials encountered, record details for each boring, and record the depth of each water bearing zone. This information must be submitted to the Parsons project manager.

7. Manage the residual soil and grout as directed by Section 16.3.12.

8. Mark the boring location with a stake or flag so the location can be surveyed.

9. Decontaminate the equipment.

16.3.8 Aquifer Slug Tests

A slug test is a single-well hydraulic test used to determine the hydraulic conductivity of an aquifer in the immediate vicinity of the screened interval of the tested well. Slug tests can be used for both confined and unconfined aquifers that have a transmissivity of less than 7,000 square feet per day. Slug testing can be performed using either a rising head or a falling head test. This section describes the slug test that uses both methods in sequence.

Slug tests are used to test properties of aquifers with rocks or unconsolidated deposits of low to moderate hydraulic conductivity. Testing of several wells is necessary to characterize an aquifer because slug tests only measure aquifer properties immediately adjacent to the borehole or well. The water level shall be static before the test begins. That is, it must not be recovering or receding as a result of sampling, development, pumping of nearby wells, or related activities. The test shall be performed using a slug or by withdrawing water from the well. No fluid shall be put into the well.

All valid water-level or drawdown versus time data resulting from these tests should be appended to the draft and final reports describing the analysis of these tests. These field data should be provided in ASCII electronic format. Additionally, these field data and the calculated hydraulic conductivity values will be included in the report and submitted to the Army. A field slug test report form is attached in Appendix C.

When designing a slug test, the geologist should identify the following parameters: (1) volume of the slug, (2) diameter of the well, (3) depth and length of the screened interval, (4) method and frequency of water level measurements, (5) barometric pressure, and (6) the method used to analyze the data.

16.3.8.1 Definitions

Hydraulic Conductivity (K). A quantitative measure of the ability of porous material to transmit water; defined as the volume of water that will flow through a unit cross-sectional area of porous or fractured material per unit time under a unit hydraulic gradient.

Transmissivity (T). A quantitative measure of the ability of a given thickness of an aquifer to transmit water. It is the product of the hydraulic conductivity and the saturated thickness of the water-bearing zone.

Rising Head Test. A test used in an individual well within the saturated zone to estimate the hydraulic conductivity of the surrounding formation adjacent to the screened interval by lowering the water level in the well and measuring the rate of recovery of the water level. The water level may be lowered by removing a quantity of water or a submerged solid slug from the well. The well screen may be fully or partially saturated during the test.

Falling Head Test. A test used in an individual well to estimate the hydraulic conductivity of the surrounding formation adjacent to the screened interval by raising the water level in the well by insertion of a solid slug or quantity of water, and then measuring the rate of drop in the water level. If the static water level is below the top of the screen or open section of the well, a falling-head test should not be performed.

16.3.8.2 Equipment and Materials

The following equipment will be used to conduct a slug test:

- Teflon®, PVC, or metal slugs;
- Nylon or polypropylene rope;
- Electric water-level indicator;

- Pressure transducer/sensor (10 psi recommended);
- Field logbook/forms; and
- Automatic data recording instrument (e.g., Hermit Environmental Data Logger®, In-Situ, Inc. Model SE3000, or equivalent).

16.3.8.3 Test Procedures

Hydraulic testing will be completed on wells that have been properly developed and in which water levels have stabilized. During the slug test, the water level change should be influenced only by the introduction (or removal) of the slug volume. Other factors, such as inadequate well development or extended pumping, may lead to inaccurate results. The Parsons field team will determine when static equilibrium has been reached in the well. The pressure transducer, slugs, and any other downhole equipment will be decontaminated prior to and immediately after the performance of each slug test using the procedures described in Section 16.3.11.

One falling and one rising head test will be performed at each selected monitoring location. The following steps describe the falling and rising head slug test procedure:

1. Decontaminate all downhole equipment prior to initiating the test.

2. Open the well. Where wells are equipped with water-tight caps, the well should be unsealed at least 24 hours prior to testing to allow the water level to stabilize. The protective casing will remain locked during this time to prevent vandalism.

3. Prepare the aquifer slug test report form (attached in Appendix C) with entries including:

    a. Well number, project number, and project name,
    b. Aquifer testing team,
    c. Climatic data,
    d. Measuring equipment being used, and
    e. Date.

4. Measure the static water level in the well to the nearest 0.01 foot.

5. Lower the decontaminated pressure transducer into the well and allow the displaced water to return to its static level. This can be determined by periodic water-level measurements until the static water level in the well is within 0.01 foot of the original static water level. At least one foot should be allowed between the bottom of the well and the transducer, and there must be enough space

between the transducer and the water table to submerge the slug (verify length of slug needed prior to test).

6. Prepare the data logger for the falling head test in accordance with the user's manual. Set the data logger to record in logarithmic mode and reference the transducer to zero prior to the test. Follow the user's manual for proper operation of the data logger.

7. Turn on the data logger, initiate data recording, and quickly lower the slug into the well using clean nylon rope so that the top of the slug is just below the static water level previously measured in the well, being careful not to disturb the pressure transducer. The hollow stainless steel slug should contain machined ends onto which stainless screw caps with o-ring gaskets fit. The slug should be filled with potable water for the test. In some instances a thinner, solid 2-foot long slug should be used for the slug test if the 5-foot slug becomes repeatedly snagged on the transducer cable at the start of the test, thereby disrupting the test results.

8. Stop data recording when the water level reaches 80 percent of the original static water level and stabilizes to 0.02 feet over a 5-minute time period. During the test, water levels can be monitored using the data logger display.

9. Prepare data logger for the rising head test in accordance with the user's manual. Set the data logger to record in logarithmic mode and reference the transducer to zero prior to the test

10. Initiate data recording again and quickly remove the slug from the well (make sure not to disturb the transducer cable) and continue the test until the water level in the well has stabilized. The well will be considered stabilized for termination purposes when it has recovered to within 10 percent of the original static water level.

11. Terminate data recording when the water level reaches 80 percent of the original static water level and stabilizes to 0.02 feet over a 5-minute time period.

12. Remove the transducer from the well and decontaminate.

16.3.8.4 Slug Test Data Analysis

Data obtained during slug testing will be analyzed using the method of Bouwer and Rice (1976) and Bouwer (1989) for unconfined conditions.

16.3.8.5 Other Aquifer Test Methods

Other aquifer test methods could be used to estimate the aquifer hydraulic parameters (e.g., transmissivity and storativity) and if needed, will be specified in the SS-WP. Below are some of the test methods that could be used to estimate aquifer hydraulic parameters.

- ASTM D-4630-96(2002), Standard Test Method for Determining Transmissivity and Storage Coefficient of Low-Permeability Rocks by In Situ Measurements Using the Constant Head Injection Test

- ASTM D4631-95(2000), Standard Test Method for Determining Transmissivity and Storativity of Low Permeability Rocks by In Situ Measurements Using Pressure Pulse Technique

- ASTM D2434-68(2000), Standard Test Method for Permeability of Granular Soils (Constant Head)

16.3.9 Test Pit/Trench Excavation

The primary objective of test pitting is to provide a means for the visual evaluation of subsurface soils and the collection of soil samples or to investigate anomalies discovered during the geophysical surveys. Test pits and trenches shall be excavated by hand or by power equipment to permit detailed observation of in-situ materials. Hand digging around specific materials encountered may be necessary to prevent puncture or damage of the objects. Sufficient space should be maintained between trenches/pits for the placement of soil stockpiled for cover as well as to allow access and free movement by support vehicles and operating equipment. The protocol presented in this section is consistent with the guidance document developed by USEPA (1987). Safe work practices for excavation and test pitting, which can be found in the Generic Site-Wide Health and Safety Plan (Parsons, 2005), should be used for any test pit/trench excavation activities.

16.3.9.1 Equipment

- Excavator
- Shovels and other hand tools
- Tape measure
- Folding ruler
- Test Pit Record form (Appendix C)
- FID or PID
- Field book
- Decontamination equipment as described in Section 16.3.11.

- Level D health and safety equipment as described in the Generic Site-Wide Health and Safety Plan (Parsons, 2005).
- Camera

16.3.9.2 Field Procedures

Test pits and trenches will be excavated by backhoe to permit detailed observation of in-situ subsurface soils. Hand digging around specific materials or utilities encountered may be necessary to prevent puncture or damage of objects. Test pits are typically 3 to 7 feet wide and 8 to 15 feet deep; test trenches are typically 3 to 6 feet wide and may be extended for any length required to reveal conditions along a specific profile line. However, actual excavation widths and depths are dependent on the backhoe size, depth to groundwater, and soil conditions encountered and will be specified in the SS-WP.

1. Conduct pre-excavation check as described in Section 16.3.2.

2. Inspect all excavating equipment.

3. Decontaminate all excavating equipment as per Section 16.3.11 prior to starting the work. Inspect all equipment to assure that residual oils, asphalt, grease, grout, soil, etc. has been removed.

4. Mark the location of the proposed test pits and trenches in the field.

5. While excavating in parking areas or improved grassy areas, excavated materials will be stockpiled on polyethylene sheets beside the test pit. While excavating in landfill areas with unimproved dirt surfaces, only obviously contaminated materials, different from surface material, will be placed on plastic, where practical. The staging area should include run-off containment features. Keep the top 6 to 12 inches of soil separate from the deeper soil so that it can be used as cover material when the test pit is backfilled. The size and depth of the test pit or trench will be described in the SS-WP.

6. When appropriate, air sampling will be performed during test pitting to support two broad-based directives: the protection of workers and the protection of public safety. Air sampling shall be performed using a Photoionization Detector with an 11.7 mV lamp to monitor for volatile organic compounds in the air. It will be used to monitor air in the breathing space of workers during test pit activities. The procedures for any necessary air monitoring will be specified in the SS-WP or site-specific Health and Safety Plan.

7. The field team will keep detailed records on the Test Pit Record form (attached in Appendix C) including:

a. Soil descriptions and stratigraphic changes;
b. Relative soil moisture; depth to groundwater (if encountered);
c. Visible signs of staining (natural or otherwise);
d. Level of difficult of excavation
e. Results, type, and time of monitoring measurements;
f. Sampling locations, depths, and time;
g. Time of excavation;
h. Reason for terminating excavation; and
i. Type of excavator.

8. Significant features exposed by the test pit and trench will be photographed, if possible, with a scale included in the photographs to indicate dimension. The photographs of test pits will be marked to include site number, test pit number, depth, description of feature, and date of photograph. Where photographic records are collected, a detailed log will be maintained noting location, feature, time, and date.

9. Trained personnel adhering to appropriate safety and health standards shall collect samples from the test pit as directed by the field team leader. The samples will be obtained in accordance with split spoon sampling SOPs presented in Section 16.4.2.

10. **No personnel will be allowed to enter the excavation once the excavation is more than 2 feet deep**, unless proper safety precautions have been taken, such as wall slopes or trench boxes, in accordance with OSHA standards.

11. Any excavated containers filled with liquid or solid substances will be overpacked, tested, and appropriately disposed in accordance with SOPs presented in Section 16.3.12.

12. If the pit is not to be closed immediately after the required samples have been obtained, the excavation will be barricaded to prevent accidental entry by personnel working on the site.

The following describes the procedures for test pit and trench termination/completion:

1. Each test pit and trench will be backfilled with the excavated material. The material will be placed in lifts of 1 to 2 feet. Each lift will be compacted with the bucket of the excavator. The segregated surface soil will be backfilled last. The ground surface conditions should be returned to the existing conditions after the completion. Previously paved surfaces removed for test pit excavation will be graded and patched with bituminous pavement matching the thickness of the original pavement to form a level surface with the adjacent pavement.

2. Upon closure of the excavation, mark the test trench or pit with a stake or flagging, labeled with the test pit or trench number, so that its location can be surveyed.

3. Decontaminate the backhoe bucket and arm upon completion of excavation activities in accordance with Section 16.3.11 before new excavations begin.

4. All wastes generated in association with test pit or trench operations will be managed as per SOP presented in Section 16.3.12.

16.3.10 Sample Location Survey

This section outlines the location survey activities to be conducted during the field activities. The surveying data will be used to develop the technical reports for the site and to support the field effort.

16.3.10.1 Sample Location Survey

The locations and elevations of monitoring wells, soil borings, surface soil samples, sediment samples and surface water samples will be surveyed by a surveyor registered in the State of New York. The elevation of the ground surface adjacent to each surveyed point and measurement datum will be measured relative to an existing benchmark location referencing the Base grid system. Survey of the new wells will take place as follows:

- Horizontal locations for monitoring wells, soil borings, surface soil, sediment and surface water sample locations will be measured relative to Northing and Easting in State Planar Coordinates, North American Datum of 1983 (NAD 1983), accuracy ± 0.1 feet.

- The elevation of the ground surface adjacent to each monitoring well will be measured relative to North American Vertical Datum of 1988 (NAVD 1988), accuracy ± 0.1 feet at stake or pin in collar.

- The elevation of the top of the well protective casing and top in the well casing will be measured relative to NAVD 1988, accuracy ± 0.1.

- Monitoring wells will have three elevations with varying levels of accuracy; the first for the top of well's PVC inner casing at a notch placed by the surveyor, a second for the top of the well's protective outer casing at the crown of the cap, and the last for the elevation at a pin placed in the collar of the well at the ground.

All monitoring wells shall be resurveyed at a minimum every five years, with the approval of the Army.

Other potential site surveys include preliminary alignment survey, preconstruction alignment survey; and post construction as-built survey. These surveys will also be conducted by a surveyor registered in the State of New York. Requirements for other site-specific surveys, if warranted, will be covered in the SS-WP.

16.3.10.2 Survey Grids

The geophysical investigation will incorporate two distinct methods of survey and mapping of anomaly locations. The first method will involve the establishment of a survey grid with size specified in the SS-WP on a planimetric map prior to entering the field. The grid will first be established on a map and submitted to Parsons and USACE for approval. Once approved, the associated grid will then be surveyed in to its proper location once the field investigation begins.

Land survey activities include field survey and mapping of each grid using grid coordinates provided by Parsons. The corners of each grid shall be referenced to the New York State Plane Grid System based on the North American Datum of 1983 (NAD 1983). All grid locations will be surveyed, the coordinates recorded, and semi-permanent marker stakes will be advanced at each grid corner prior to investigation of a grid. The corners of the individual grids will be established to a post-processed accuracy of ± one foot. Grids will be oriented north-south or east-west, where possible, to enable quick tracking of grid locations and access to each grid during subsequent investigations.

Approved survey techniques will be used to place the southwest corner of each survey grid to within approximately 25 meters of their proposed locations in this Work Plan. The remaining corners of the survey grids will then be located. If the location of a grid falls in an area that would not be accessible to the geophysical survey crew (i.e. a ravine), or is in an area with significant cultural interference (such as irrigation piping), that grid will be relocated up to 50 meters from the originally selected location.

Grid corners may be laid out using a combination of surveyors' equipment, differential GPS equipment, and trigonometry. At a minimum, the southwest corner of each grid will be established using GPS or surveying methods. The horizontal accuracy of the geophysical surveys and the ability of the OE characterization/investigation team to reacquire anomalies will be greatly dependent upon the placement of the grid corners. The angle between the survey grid boundaries must be as close to 90 degrees as possible, and will periodically be verified for "squareness" by the survey crews. A grid found to be out of square by more than 1 foot (measured diagonally from grid corner to grid corner) will be resurveyed. EM-61 data collected from a grid that is found to be out of square will either be corrected (if possible) or the grid will be adjusted and resurveyed with the EM-61.

16.3.11 Equipment Decontamination

Sample collection devices will be decontaminated prior to each use. All potentially hazardous rinse liquids and materials will be containerized and properly disposed, in accordance with Section 16.3.12. Decontamination methods will be modified if necessary, based on the SS-WP. Equipment decontamination will be conducted in a clean area free of dust. Precautions will be taken to minimize any impact to the surrounding area that might result from decontamination operations, and any deviations from these procedures will be documented in the field notebook and on the appropriate sampling record.

Laboratory-supplied sample containers will be cleaned and sealed by the laboratory. The type of container provided and the method of container decontamination will be documented in the laboratory's permanent record of the sampling event.

Decontamination procedures for sample collection equipment, submersible pump and water level indicator, above-ground pump, and drill rigs are provided below. Unless otherwise specified, Liqui-Nox (or a non-phosphate equivalent) will be used as the cleaning reagent. Alconox (or equivalent) can be substituted if the sampling equipment will not be used to collect phosphorus or phosphorus-containing compounds. Unless otherwise specified, ambient temperature water may be substituted in the hot water bath or rinses. Unless otherwise specified, pesticide grade solvent (isopropanol) should be used for decontamination. This grade of alcohol must be purchased from a laboratory supply vendor. Rubbing alcohol or other commonly available sources of isopropanol **are not acceptable**.

16.3.11.1 Decontamination of Sample Collection Equipment

Sample collection equipment (e.g., bailers, stainless steel scoops/spoons, trowels, coring bits, and hand auger bucket) used to collect groundwater, surface soil, subsurface soils, surface water, or sediment will be decontaminated by the following process:

1. Wash equipment with hot tap/potable water.

2. Soak equipment in a hot detergent (Alconox or Liquinox) solution. Use Liquinox if the sampling equipment will be used to collect phosphorus or phosphorus-containing compounds. A scrub brush will be used to remove dirt and surface film.

3. Rinse thoroughly with tap water.

4. For Teflon®, stainless steel, and glass sampling equipment:

- If samples for trace metals or inorganic analytes (other than nitrogen components such as nitrate and nitrite) will be collected with the equipment and the equipment **is not** stainless steel, thoroughly rinse (wet all surfaces) with 10% reagent grade nitric acid. If sampling for ultra-trace levels of metals, use an ultra-pure grade acid. Use reagent grade 10% hydrochloric acid when nitrogen components are to be sampled.

- If samples for organics will be collected, rinse with pesticide grade isopropanol.

5. For plastic sampling equipment, thoroughly rinse (wet all surfaces) with 10% reagent grade nitric acid (for analytes other than nitrogen components) or reagent grade 10% hydrochloric acid (for nitrogen component samples). Check manufacturer's instruction for cleaning restrictions and/or recommendations.

6. Rinse thoroughly with deionized, organic-free, reagent grade water.

7. Remove excess water and allow equipment to air dry.

8. Wrap equipment in aluminum foil, shiny side out.

9. Rinse water and detergent water will be replaced with new solutions daily, when visibly impacted by residuals, or between sampling areas or changes in operations.

16.3.11.2 Decontamination of Submersible Water Level Indicator

Submersible water level indicators will be decontaminated with the following procedure:

1. Wash outside of water level indicator and hoses/lines with laboratory-grade detergent (Alconox or Liquinox) and water.

2. Rinse outside of water level indicator and hoses/lines with potable water.

3. Rinse outside of water level indicator and hoses/lines with deionized, organic-free, reagent grade water.

4. Remove excess water.

5. Wrap water level indicator in plastic.

16.3.11.3 Sample Tubing Decontamination

Sample tubing will be decontaminated by the procedures listed below prior to use and following sampling of each well. The SOP was modified from the SOPs developed by Florida DEP (2004).

1. Check tubing for discoloration and elasticity. Remove discolored tubing from use until it can be cleaned. If the discoloration cannot be removed, discard the tubing. Discard any tubing that has lost its elasticity.

2. Transport all tubing to the filed in precut, **precleaned** sections.

3. Teflon®, Polyethylene and Polypropylene Tubing

   It is recommended that **used tubing not to be used for sampling**. If warranted, used tubing has to be cleaned in laboratory. Field cleaning is not recommended. An SOP for used tubing cleaning will be developed and presented in the SS-WP if warranted. Follow the following procedures to clean new tubing unless the manufacturer/supplier provides certification that the tubing is clean.

   3.1 Teflon®

   3.1.1 Rinse outside of tubing with pesticide-grade isopropanol

   3.1.2 Flush inside of tubing with pesticide-grade isopropanol.

   3.1.3 Dry overnight in drying oven or equivalent (zero air, nitrogen, etc.)

   3.2 Polyethylene and Polypropylene

   3.2.1 Clean the exterior and interior of the tubing by soaking in hot (or ambient temperature if not practical) Liqui-Nox or Alconox detergent solutions. Do not use Alconox for sampling for phosphorus or phosphorus-containing compounds.

   3.2.2 Thoroughly rinse the exterior and interior of the tubing with tap water, followed by deionized, organic-free, reagent grade water.

4. Flexible Tubing used in Pump Heads of Automatic Samplers and Other Peristaltic Pumps.

Replace tubing after each sampling point if samples are collected through the tubing. Unless the pump is deployed to collect samples from the same location over a long period of time, remove and wash the tubing after each sampling event.

4.1 Flush tubing with hot tap water then detergent solution.

4.2 Rinse thoroughly with hot tap water.

4.3 Rinse thoroughly with deionized, organic-free, reagent grade water.

4.4 If used to collect metal samples, flush the tubing with a 10% reagent grade nitric acid, followed by thorough rinsing with analyte-free water. If used to collect both metals and nitrogen components use 10% reagent grade hydrochloric acid.

4.5 Install tubing in peristaltic pump or automatic sampler.

4.6 Cap both ends with aluminum foil or equivalent.

5. Stainless Steel Tubing

5.1 Using appropriate detergent solution to scrub the interior and exterior surfaces.

5.2 Rinse with hot tap water.

5.3 Rinse with deionized, organic-free, reagent grade water.

5.4 If volatile or extractable organics are to be sampled, rinse all surfaces with pesticide grade isopropanol. Use enough solvent to wet all surfaces with free flowing solvent.

5.5 Allow to air dry or thoroughly rinse with deionized, organic-free, reagent grade water.

6. Glass Tubing

6.1 Use new glass tubing.

6.2. If volatile or extractable organics are to be sampled, rinse with detergent grade isopropanol.

6.3 Air dry for at least 24 hours.

6.4 Wrap in aluminum foil or untreated butcher paper to prevent contamination during storage.

6.5 Discard tubing after use.

7. Miscellaneous Non-Inert Tubing Types (Tygon®, Rubber, PVC, Etc.)

7.1. New Tubing

7.1.1 As a general rule, new tubing may be used without preliminary cleaning.

7.1.2 Protect new tubing from potential environmental contamination by wrapping in aluminum foil and sealing in untreated plastic bags or keep in the original sealed packaging unit use.

7.1.3 If new tubing is to be used to collect samples, thoroughly rinse the tubing with sample water (i.e., pump sample water through the tubing) before collecting samples.

7.2. Reused Tubing

7.2.1. Flush tubing with appropriate detergent solution (Liqui-Nox, Alconox, or equivalent).

7.2.2 Rinse exterior and interior thoroughly with hot tap water.

7.2.3 Rinse exterior and interior thoroughly with deionized, organic-free, reagent grade water.

7.2.4. If used to collect metals and nitrogen-containing compounds, flush the tubing with 10% reagent grade nitric acid, followed by a thorough rinse with deionized, organic-free, reagent grade water.

7.2.5 If used to collect metals and nitrogen-containing compounds, use the 10% reagent grade hydrochloric acid rinse, or thoroughly rinse with hydrochloric acid after a nitric acid rinse.

7.2.6. Cap ends in aluminum soil and store in clean, untreated plastic bags to prevent contamination during storage and transport.

16.3.11.4 Decontamination of Submersible Pumps

Submersible pump (including support cable and electrical wires which are in contact with the sample) will be decontaminated by one of the procedures listed below prior to use and following sampling of each well. The SOP was modified from the SOPs developed by Florida DEP (2004).

Procedure 1 – Pumps Used for Purging and Sampling Metals and/or Volatile and Extractable Organics

1. Clean pump exterior following steps presented in Section 16.3.11.1. Omit the solvent rinse if the pump body is constructed of plastic (e.g., ABS, PVC, etc.)

2. If used only for purging, thoroughly flush the pump with water before purging the next well, followed by steps 4 through 6 presented below.

3. If used for purging and sampling, completely disassemble the pump (if practical) and decontaminate between each well. When used for purging and sampling and the pump cannot be (practicably) disassembled, then clean the internal cavity/mechanism by pumping five gallons of tap/potable water and laboratory-grade detergent (Alconox or Liquinox), followed by five gallons of tap water, and finally, five gallons of deionized, organic-free, reagent grade water.

4. Clean sample tubing as presented in Section 16.3.11.3.

5. Remove excess water and allow equipment to dry.

6. Wrap pump hose in plastic, and pump in aluminum foil.

* Please note that when decontaminating centrifugal pumps manufactured by GRUNDFOS, the motor coolant chamber contains water and potential contaminants from prior usage. Therefore, to avoid cross contamination, the coolant fluid must be removed and replaced. See manufacturer's installation and operating instructions for further details.

Procedure 2 – Pumps Used for Purging and Sampling all Analytes except Metals and Volatile and Extractable Organics

1. Scrub the exterior of the pump with appropriate metal-free, phosphate-free, or ammonia-free detergent solution (e.g., Liqui-Nox solution).

2. Rinse the exterior with tap water and deionized, organic-free, reagent grade water.

3. Rinse the interior of the pump and tubing by pumping tap or deionized, organic-free, reagent grade water through the system using a clean bucket or drum.

4. Remove excess water and allow equipment to dry.

5. Wrap pump hose in plastic, and pump in aluminum foil.

* Please note that when decontaminating centrifugal pumps manufactured by GRUNDFOS, the motor coolant chamber contains water and potential contaminants from prior usage. Therefore, to avoid cross contamination, the coolant fluid must be removed and replaced. See manufacturer's installation and operating instructions for further details.

16.3.11.5 Decontamination of Above-Ground Pumps

Above-ground pump will be decontaminated by the procedures listed below prior to use and following sampling of each well. The SOP was modified from the SOPs developed by Florida DEP (2004).

1. For pumps used only for purging, the exterior of the pump must be free of oil and grease, followed by the steps 3 described as below.

2. For pumps used for sampling, clean the exterior of the pump with a detergent solution followed by a tap water rinse. Use clean cloths or unbleached paper towels that have been moistened with the appropriate solution to wipe down the pump.

3. Clean the tubing that contacts the formation water according to the appropriate protocol specified in Section 16.3.11.3.

* Please note that when decontaminating centrifugal pumps manufactured by GRUNDFOS, the motor coolant chamber contains water and potential contaminants from prior usage. Therefore, to avoid cross contamination, the coolant fluid must be removed and replaced. See manufacturer's installation and operating instructions for further details.

16.3.11.6 Decontamination of the Drilling Rig and Heavy Equipment

The drilling rig and other heavy equipment will be decontaminated with the following procedure:

1. Any portion of the drilling rig that will be over the borehole, including hollow stem augers, will be cleaned with pressurized hot water.

2. Down-hole tools such as augers will be brushed cleaned using soap and tap water if pressure cleaning does not remove particulate matter.

3. Split spoons, used to collect soil samples, will be cleaned as described in Section 16.3.11.

4. Cleaned down-hole equipment such as augers, will be placed on clean tarps, racks, or sawhorses to dry.

5. After drilling equipment has been allowed to dry, it will be covered with clean, unused plastic.

16.3.11.7 Decontamination of Temporary Well Casing and Screen

The well points, screens and associated riser pipe must be decontaminated prior to installation using the following procedure:

1. Remove all adherent soil material with a stiff wire brush,

2. Wash well point and associated rise pipe and couplings with a laboratory glassware detergent,

3. Rinse with potable water and/or steam clean, and

4. Rinse the interior of well point and riser with distilled and de-ionized ASTM Type II water.

Note: for proper decontamination stronger cleaner agents are recommended with the tool has been exposed to heavy contamination. This can be performed prior to Step 2, above.

16.3.11.8 Decontamination of Filtration Equipment

Filtration equipment will be decontaminated by one of the procedures listed below prior to use. The SOP was modified from the SOPs developed by Florida DEP (2004).

Procedure 1 – Dissolved Constituents Using In-line, Molded and Disposable Filter Units

1. Peristaltic Pump

1.1. Clean the exterior of the pump with a detergent solution followed by a tap water rinse. Use clean cloths or unbleached paper towels that have been moistened with the appropriate solution to wipe down the pump.

1.2 Clean the tubing that contacts the formation water according to the appropriate protocol specified in Section 16.3.11.3.

1.3. Clean the pump head tubing following step 4 presented in Section 16.3.11.3.

1.4. If Teflon® tubing is used, clean following the step 3 in Section 16.3.11.3.

1.5. Clean other tubing types such as polyethylene according to the step 7 in Section 16.3.11.3.

2. Other Equipment Types (e.g., pressurized Teflon® bailer)

2.1. Follow the appropriate cleaning regimen specified in Section 16.3.11.1 (Decontamination of Sample Collection Equipment) for other types of equipment that utilize in-line, molded and disposable filters.

Procedure 2 – Dissolved Constituents Using Non-disposable Filtration Units (e.g., Syringes, "Tripod Assembly")

1. Stainless Steel or Glass Units

1.1. Follow the appropriate cleaning regimen specified in Section 16.3.11.1 (Decontamination of Sample Collection Equipment), assembling and applying pressure to the apparatus after each rinse step (water and acid) to drive rinsing solution through the porous filter holder in the bottom of the apparatus.

1.2. Remove and clean any transfer tubing according to the appropriate cleaning procedures specified in Section 16.3.11.3.

1.3. Assemble the unit and cap both the pressure inlet and sample discharge lines (or whole unit if a syringe) with aluminum foil to prevent contamination during storage.

1.4. If the unit will not be used to filter volatile or extractable organics, seal the unit in an untreated plastic bag to prevent contamination.

2. Reusable In-Line Filter Holders

2.1. Clean using the appropriate cleaning regimen specified in Section 16.3.11.1 (Decontamination of Sample Collection Equipment, assembling and applying pressure to the apparatus after each rinse step (water and acid) to drive rinsing solution through the porous filter holder in the bottom of the apparatus.

2.2. Assemble the unit and wrap with aluminum foil to prevent contamination during storage.

2.3. If the unit will not be used to filter volatile or extractable organics, seal the unit in an untreated plastic bag to prevent contamination.

3. Filters

3.1. Do not clean filters. Use a new filter for each sample.

3.2 Flush the filter with 30-50 mL of deionized, organic-free, reagent grade water, or an inert gas (nitrogen) to remove atmospheric oxygen; or insert the filter on the high pressure side (i.e., on the delivery side) of the pump. Hold the filter upright with the inlet and outlet vertical. Pump water from the aquifer through the filter until all atmospheric oxygen has been removed.

16.3.11.9 Decontamination of Permanent Monitoring Well Casing and Screen

Before installation, field cleaning of the well casing must consist of a manual scrubbing to remove foreign material and steam cleaning, inside and out, until all traces of oil and greases are removed. Special attention should be given to threaded joints or weld burn residues. The casing should then be handed and stored in such manner so as to prevent cross contamination prior to installation.

16.3.12 Investigation Derived Waste Disposal

This section provides the general procedures for containing, sampling, and disposing of investigation derived waste. IDW may include, but is not limited to soil, sediment, purge water, drilling water, decontamination water, excavation spoils, excavation water, sampling and decontamination equipment, and personal protective equipment (PPE). The objective is to ensure that any waste generated as a result of field activities is disposed of in accordance with applicable local, state, and federal laws and regulations.

16.3.12.1 Containerization

Unless otherwise specified in this generic SAP or SS-WP, all IDW generated during fieldwork activities will be segregated by type and location (if warranted) and placed in sealed 55-gallon drums.

At the completion of the project, any drums will be disposed appropriately. PPE and sampling equipment such as tubing will be disposed as uncontaminated refuse and the rationales are provided in Section 16.3.12.3.

Decontamination Fluids and Calibration Fluids. Decontamination fluids (including steam condensate from steam cleaning of equipment and rinse water) and calibration fluids will be collected in DOT-approved 55-gallon drums. The drums will be labeled as investigation derived wastewater and temporarily stored in a secured area to be determined prior to commencement of field activities. The drums will be stored on wooden pallets in a plastic-lined containment area or in other approved secondary containment structures pending characterization and disposal.

Drill Cuttings and Surface Soil from Well Pad Installation. Subsurface soil from drill cuttings and surface soil from well pad installation will be contained in 55-gallon drums. The soils will be segregated by drill location as is practical. The drums will be labeled as investigation derived waste soils from the corresponding boring or source area and temporarily stored in a secured area to be determined prior to commencement of field activities. The drums will be stored on wooden pallets in a plastic-lined containment area or in other approved secondary containment structures pending characterization and disposal.

Development and Purge Water. All development and purge water will be contained in 55-gallon drums. The drums will be labeled as investigation derived wastewater and temporarily stored in a secured area to be determined prior to commencement of field activities. The drums will be stored on wooden pallets in a plastic-lined containment area or in other approved secondary containment structures pending characterization and disposal.

16.3.12.2 Sampling and Evaluation

IDW will be sampled and analyzed (if necessary) in accordance with the SS-WP. Analytical results (e.g., TCLP results and waste concentration results) will be used to determine the final disposition of the waste.

The IDW strategy for drum contents classification is depicted in Figure 4. As a first step, the Toxicity Characteristic Leaching Procedure (TCLP) criteria specified in the 6 NYCRR, Part 371, Section 371.3 will be used for RCRA hazardous or non-hazardous classification**.** If TCLP data are not available, as an alternative, the "twenty times rule" described in the NYSDEC Spill Technology and Remediation Series (STARS) MEMO #1 (NYSDEC, 1992) can be used for soils. The "twenty times rule" compares the soil concentrations to twenty times the TCLP regulatory levels). This represents the soil concentration that would be classified as hazardous by exceeding the TCLP levels, assuming 100% extraction efficiency. Parsons made the conservative assumption that if one soil sample associated with

the drum contents exceeded this limit then the entire drum would be characterized as RCRA hazardous waste.

Secondly, waste ignitability, corrosivity, reactivity, and toxicity will be evaluated against RCRA criteria. If these data are not available, site investigation data (e.g. detected analyte concentrations in soils, water, and drummed materials, water pH) will be used to evaluate whether the waste is *characteristic* hazardous waste (i.e., ignitability, corrosivity, reactivity, or toxicity above RCRA criteria for a characteristic hazardous waste).

IDW determined to be non-hazardous waste according to the TCLP and RCRA definition, will further be evaluated to determine if the IDW were contaminated based on soil TAGM criteria or NYSDEC groundwater standards for groundwater or purge water. This was required to evaluate compounds detected without TCLP data. If the soil result exceeded a TAGM or the water result exceeded a NYSDEC groundwater standard then the IDW was classified as contaminated. If the soil data did not exceed a TAGM value and the water results did not exceed a groundwater standard then the IDW was classified as uncontaminated.

The next step in the IDW evaluation process was to consider the threat or risk that the contaminated IDW may contribute to human health and the environment. IDW that poses an unacceptable risk or threat will then be disposed of off-site as hazardous waste. This determination involved comparison of each soil data point of the contaminated drums to ten times the TAGM value. If any soil concentration data point exceeded ten times the TAGM value then the drum contents, if disposed of on-site, is considered an unacceptable risk to human health and the environment and the drum will be disposed of off-site. Exceptions to this criterion were made if the exceedances to the ten times the TAGM value were due to non-toxic metals such as calcium, iron, manganese, potassium and sodium.

Parsons will use ten times the TAGM value as the criterion for determining whether or not the IDW poses any threat. The factor of 10 was applied due to the conservative nature of the TAGM values and the fact that this criterion has been acceptable to NYSDEC for similar SEDA projects in the past.

For the IDW waste including decontamination fluids, sampling equipment such as tubing, personal protection equipment, and purge water during the well development and sampling, the disposal evaluation involved the following steps. Under RCRA, wastes are classified as hazardous if they are listed wastes or characteristic wastes. Waste specific information, such as manifests, bills of lading, storage records or records of waste sources must be used to document that a waste is a RCRA-listed waste; otherwise, in the absence of any other information, the waste in question cannot be considered a listed waste. Drummed cuttings, PPE, sampling tubing, or purge water generally are not listed hazardous wastes since these material produced at the Seneca sites generally do not meet any of the regulatory definitions described in 40 CFR 261, (i.e. F-, K-, P- or U- listed wastes). The only listed waste that may be generated during the

investigation program at SENECA is waste that contained methanol. Methanol may be used to preserve soil/sediment samples for VOC analysis. For the Depot projects, preserved bottles will be ordered from the laboratory; therefore, unless accidentally spilled, methanol is not expected to be in any IDW waste. Wastes containing spilled methanol will be considered an F003 listed hazardous waste. An F-listed waste classification refers to non-specific hazardous waste sources that contain methanol as a component of a spent solvent mixture. In order to limit the generation of hazardous waste, methanol spilling will be reported to the project manager and the waste containing methanol should not be mixed with soils or other liquids. Additionally, during the decontamination process, washable rubber bibs will be worn to prevent contamination of disposable PPE. Overall, drummed cuttings, PPE, sampling tubing, and purge water are generally not considered hazardous waste and will be disposed of as uncontaminated refuse.
Table 22 presents the RCRA Hazardous Waste Determination Criteria and Table 23 summarizes the disposal classification process.

16.3.12.3 Disposal

IDW will be disposed appropriately based on the sampling and evaluation results. RCRA hazardous waste will be disposed of off-site by a permitted hazardous waste disposal subcontractor. Uncontaminated material will be returned to the location where it was generated. No hazardous contaminated material but with no threat to human health or the environment (e.g., soil with concentrations above TAGM but below ten times the TAGM levels) will also be returned to the location where it was generated. Uncontaminated water will be discharged to the Seneca County Sewer District No. 2 (the District) via an on-site sanitary sewer. No hazardous contaminated material with threat to human health or the environment (e.g., soil with concentrations above ten times the TAGM levels) will be disposed off-site. Waste disposal companies and disposal facilities will be identified in the SS-WP. All waste manifests will be reviewed by Parsons project manager as documentation of the disposal activities.

In instances where only a monitoring well was installed, with no soil sampling performed, the disposal of the soils generated during well installation will be the same as the disposal option for the groundwater (i.e. groundwater requires off-site disposal, therefore soils from associated well installation will also be disposed of off-site).

The disposal of excavation spoils will be addressed on a site by site basis and will be addressed in the site-specific SAP.

With prior permission from the Seneca County Sewer District, recovered groundwater from an excavation, the water collected from decontamination operations, and other waters generated during construction will be collected and stored in tanks for on-site storage and analytical sampling, before being discharged to the Seneca County Sewer District No. 2 via an on-site sanitary sewer. Required

permits will be obtained before discharging. All waters will be appropriately tested and approved for discharge prior to release.

16.3.13 Corrective Action

A corrective action shall be initiated during the field work when changes are made in the field that do not meet the scope of work requirements or other conditions are identified that are not consistent with the SAP or SS-WP. Section 11.1 describes corrective action procedures for field activities.

16.3.14 OE/UXO Sites Sampling, Investigation, and Removal Action

This section presents a summary of the practices and procedures Parsons will use to perform sampling, investigation, and OE/UXO removal at potential OE/UXO sites at the Seneca Army Depot. Training and certification requirement for field staff working at potential OE/UXO sites are presented in Section 14 of the SAP. The health and safety requirements for working at potential OE/UXO sites are presented in the Parsons (2005) Accident Prevention Plan and Generic Site-Wide Health and Safety Plan for Seneca Army Depot Activity. SOPs for activities associated with OE/UXO investigations are attached in **Appendix H**. SOPs for other geophysical survey activities (e.g., EM-31) are provided in Section 16.3.3.

16.3.14.1 Geophysical Prove-Out

The geophysical prove-out will be required at the beginning of any OE/UXO investigation to demonstrate the capabilities of the geophysical equipment and personnel being employed during the removal action. The prove-out grid will contain several items buried by Parsons and USACE. The data will be used to evaluate the positioning and noise level produced by the array. The main purpose of the data collected over the prove-out grid is to demonstrate that the equipment and procedures used can meet the project requirements. Therefore, prove-out activities will use all proposed geophysical data collection methods. The main variables in the proposed methods are the instruments used in the data collection and the method of positioning the equipment. The method recommended based on the previous experience at Seneca is time domain EM acquisition using a three-sensor EM61-MK2 towed array and a Schonstedt™ magnetometer, as shown in the table below.

EQUIPMENT AND POSITIONING METHODS

Geophysical Instrument	Positioning Method
Schonstedt™ Magnetometer	Fiducials using local coordinates
Schonstedt™ Magnetometer	Real Time Kinematic (RTK) GPS positioning
EM61-MK2 Three-Sensor Towed Array	RTK GPS positioning
EM61-MK2 Hand-pulled System	RTK GPS positioning

Both types of instruments (Schonstedt™ magnetometer and EM61-MK2) will be used to collect data across the existing grid, and the results will be processed in an identical manner to that which will be used for the clearance surveys, ensuring that the final product of the geophysical survey will meet the project objectives. The results of the prove-out analysis will be summarized in a letter report and provided to the Army within one week of completion of the data acquisition over the prove-out grid.

16.3.14.2 Explosives Management Plan

The Explosives Management Plan (including acquisition, inventory, storage, transportation, and disposal of explosives) is presented in **Appendix H** of this SAP.

16.3.14.3 SOPs for Dynamic Events

Dynamic events such as rain and solar flares may affect geophysical data collection. Procedures for geophysical survey operations when these events occur are presented in this section. SOPs for operations under other severe weather conditions can be found in the SOP for Severe Weather Operations in **Appendix H**.

Rain

The effect of rain on geophysical operations is primarily dependent on the instrument being used and the physical site conditions (terrain and vegetation).

- Instrument: Most of the instruments commercially available are relatively water resistant. Additional measures will be taken by the survey teams (such as covering connections with plastic sheeting) to reduce the possibility of moisture impacting the instrument's electronics. When possible, survey teams will operate the instruments under very light rain conditions (drizzling). If the rain persists and the survey team leader determines that there is a potential for an impact to the data quality or that moisture could be getting into the instrument, field operations will cease and the

project geophysicist will be notified. Operations will continue after the rain has ceased or has reduced to a drizzle.

- Site Conditions: At sites where footing for the operators becomes difficult because of wet terrain or vegetation, operations will cease until the area is deemed safe by the UXOSO. The determination to stop will be made by the UXOSO, and the project team will be immediately notified.

Solar Flares

Solar flares are sun-generated phenomena, typically occurring in the afternoon, which may temporarily generate high-magnitude magnetic noise sufficient to make magnetometers, often gradiometers, and occasionally electromagnetic sensors unusable for the duration of the event. Solar flares are typically readily observable by the instrument operators as rapidly fluctuating signal readings with no apparent cultural or survey source. The PM will be alert to solar flares and temporarily cease data collection until static testing shows a cessation of the solar activity. The PM will log the time intervals when solar flare activity is observed to help determine whether any data (for digital geophysics) have been affected. The National Oceanic and Atmospheric Administration maintains a helpful website at http://spaceweather.com.

16.3.14.4 Site Clearance

Surface preparation (also referred to as "Surface Avoidance") entails the visual inspection of each clearance area for metal ordnance-related items and scrap. This activity should be performed immediately following establishment of a geophysical survey and before any subsurface anomaly investigation. Surface preparation operations will be performed by field teams consisting of two UXO technicians and four sweep personnel. Operations will be initiated by establishing a linear array with the five team members along the southern boundary of a survey grid. The first member in the array is positioned at the southwest corner of the grid. The remaining four members are spaced to the east at 5-foot intervals. Upon assembly, the members of the array proceed in a straight line toward the northern boundary of the survey grid. Based on the 5-foot spacing, each member visually surveys a 5-foot wide path. The team's leader follows the array to ensure that the array moves forward in unison and that the 5-foot spacing is maintained. Additionally, the team leader collects all identified MPPEH related items and scrap from the survey grid. Operations for surface sweep and vegetation removal will be performed in accordance with the SOP for Chipper Operations and the SOP for Mechanical Vegetation Removal, as attached in **Appendix H**.

16.3.14.5 Geophysical Investigation

Unless otherwise specified by the SS-WP, land-based geophysical survey methods will be utilized to identify and remove MPPEH at the Seneca Army Depot. These surveys will be conducted using Schonstedt™ magnetometers and the EM61-MK2 towed array system. Surveys employing Schonstedt™ magnetometers, the EM61-MK2 towed array, and stand alone EM61-MK2 pedestrian systems are hereafter referred to as "mag and flag," "towed array," and "pedestrian mode" surveys, respectively. A field data sheet form is provided in **Appendix C**.

Geophysical Data Quality Objectives

The objective of the geophysical investigation is to accurately locate and record the locations of geophysical anomalies, which could be material posing an explosive hazard. The geophysical investigation areas and identified anomalies will be mapped for subsequent evaluation (including intrusive investigations of anomalies where geophysical signal strength and amplitude suggest the potential of UXO/MPPEH). In accordance with the USACE (2002) DID OE-005-05.01, the accuracy goal for 95 percent of reacquired geophysical anomaly locations is horizontally within a one meter radius of their original surface location as marked on the dig sheet (an example of dig sheet is provided in **Appendix C**). Horizontally, 95 percent of all excavated items will be within a 35-cm radius of the reacquired location. Secondary DQOs may be developed based on the geophysical prove-out results. Variations will be noted and if they cannot be addressed in the field (i.e. equipment replacement, change in vehicle speed, etc) then a root cause analysis memorandum will be generated. If there are more than 15% "false positives", a re-evaluation of the data, detection methods being utilized, and overall project QC shall be performed. A written response explaining the reason for the excessive false positive results and a Corrective Action Plan, if appropriate, shall be submitted to the Contracting Officer within 10 days of identification of the situation.

Mag and Flag

Mag and flag surveys will be conducted in areas by UXO technicians or sweep personnel where the maneuverability of the EM61-MK2 is limited, for surface clearance, and in the vicinity of structures. This type of survey requires operators using Schonstedt™ magnetometers to identify anomalies in the field (the "mag" portion of the survey). The mag and flag survey will be initiated by establishing a linear array of magnetometer operators along the southern boundary of a survey grid. The first member in the array will be positioned at the southwest corner of the grid. The remaining members will be spaced to the east at 5-foot intervals. Using Schonstedt™ magnetometers, each member of the array will proceed in a straight line toward the northern boundary of the survey grid. Each magnetometer operator surveys a 5-foot wide path. The team's leader (a UXO technician) follows the array to ensure that the 5-foot spacing is maintained and to verify identified anomalies. Locations of confirmed

anomalies will be marked in the field with survey pin flags and recorded on a field. Data from these surveys are not recorded in a data logger, as they will be during surveys employing the EM61-MK2. The locations of these anomalies will be indicated on field data forms (i.e., dig sheets) produced after survey is completed. The marked locations can either be surveyed using a Robotic Total Station (RTS) survey system or be investigated by conducting intrusive investigative activities from a known point.
The Schonstedt™ magnetometer is a hand-held unit that employs two fluxgate sensors aligned and mounted a fixed distance apart to detect changes in the earth's ambient magnetic field caused by ferrous metal. The Schonstedt™ magnetometer responds with an audio output and a meter deflection when either sensor is exposed to a disturbance of the earth's ambient field associated with a ferrous metal target and/or the presence of a permanent field associated with a ferrous metal target. (In most cases, it will be a combination of both circumstances.) Schonstedt™ magnetometers, which are highly portable, will also be used during UXO avoidance activities and intrusive operations.

EM61-MK2 Surveys

The towed array system will consist of three EM61-MK2's attached to a platform constructed of structural fiberglass and other non-metallic pieces. It will be towed behind a small four- or six-wheel all-terrain vehicle (ATV) such as a John Deere Gator. Vehicles with a minimum of two seats are preferred so that the tasks of the driver and the geophysical equipment operator are performed by separate personnel. The selection of the vehicle will be critical as some small ATVs produce significant amounts of electromagnetic noise. The amount of such noise will be tested prior to the beginning of the survey. The array will be positioned using a GPS with RTK accuracy, such as the Trimble® 5700 or equivalent.

The EM61-MK2 operated in "Pedestrian Mode" will be used in areas inaccessible to the towed array such as the transects or the smaller areas the towed array cannot cover. The EM61-MK2 system operated in pedestrian mode coil will be positioned using local coordinates and fiducials to segment the data collection.

The data for the EM61-MK2s and the Trimble® 5700 system will be recorded on a laptop computer located on the tow vehicle via RS-232 ports. The data will be recorded using the Geometrics Maglog software. This program will record all four data streams (three EM61s and a GPS system) on hard disk, time-stamping them with the computer time. This common time stamp will ensure that all data are tied to a single consistent set of times and will remove the need for synchronization between the EM61-MK2 data logger clocks and the GPS clock as well as eliminating the effects of clock drift between the various instruments.

Maglog also graphically displays the data on screen to provide the operator with the feedback regarding the instrument operation. Visual and audible warnings can be configured for the software so that the

geophysical equipment operator will be immediately aware if any of the elements of the towed array are not functioning optimally.

Maglog records the data in the raw form that it receives from the serial port on the laptop hard disk in a separate file for each data stream (three EM61 MK2 files and one RTK GPS file). After the completion of each day (or more often as needed), the data will be transferred to the data processing computer. A single day's worth of data is expected to be on the order of several hundred megabytes.

Subsequently, the GPS will be filtered using Parsons proprietary software to remove GPS data that do not meet required positional quality tests. The filtering will be based on the positional type of each point (i.e. RTK, differential GPS, uncorrected), position dilution of precision (PDOP), and apparent velocity between points. Points that are within a specified radius from each other will also be discarded. This removes artifacts from the processed data that can results from the array "spinning" when the array is actually stationary. Small variations in the location of the array can cause the software to believe that the array is traveling in a small circle, introducing positional errors into the calculation. Removing points that are too close together removes this type of error without any decrease in the positional accuracy of the algorithm. The filter also removes records corrupted during transmission from the GPS unit to the laptop. While these corrupted data transmissions rarely occur, they can introduce significant positioning errors in the processed data.

After filtering, the complete data set is imported into Geometrics Magmapper software. This software merges the EM61-MK2 data and the GPS data to position the geophysical data. The user inputs the offset from the center of the GPS antenna to the centers of each of the three coils to position the data recorded from each of the coils. Magmapper positions the data using these offsets and the computed bearing of the GPS data. The data are then exported in Geosoft ASCII XYZ format. The exported data will include positional information in latitude-longitude format, the data from each of the four channels for each coil, battery voltage, other equipment status information, and the time stamp derived from the laptop.

This data will then be imported into the Geosoft Oasis montaj™ geophysical data processing environment using a custom script written specifically for this project. The script will automate the process for importing the data, converting the positions to New York Central State Plane coordinates and automatically leveling the data using the UX-Detect drift correction algorithm. In addition, a sum or weighted average of the four channels is calculated for use in later processing.

The static tests are then evaluated for compliance with the requirements specified in the USACE (1986) DID OE-005-05. Any spikes present in the data are manually edited. The geophysical processor then evaluates the results of the latency test to determine the instrument latency correction necessary for the data set. This corrects for delays that occur in the electronics of the EM61-MK2s and in the processing

of the data on the data recording computer. The latency correction is computed on a sensor-by-sensor basis by determining the latency value that overlaps the anomaly due to the latency test item when the array travels over the anomaly in different directions. Typically this value is between 0.2 and 0.4 seconds.

Once the latency value is determined, it is applied to the whole data set, and the sum or average channel is gridded and displayed. The display is evaluated against the information in the field notes to determine if they are consistent and whether or not the data meets expected data quality standards.

Anomaly Selection

The processor will automatically make anomaly selections on the data using the Geosoft UX-Detect Blakely algorithm. This will be done in accordance with the threshold anomaly selections as determined from the prove-out analysis. These anomaly selections will then be evaluated to determine if the response from all four channels decays in a manner consistent with an anomaly due to a buried metallic object. If not, the anomaly will not be intrusively investigated. This evaluation has proven useful in decreasing anomaly selections of noisy data and peaks that result from gridding artifacts that can arise from closely spaced lines. The remaining anomaly selections will then be merged so that closely spaced anomaly selections will be consolidated to single pick. The anomaly selections and the data will then be evaluated by the geophysical processor to ensure that the remaining anomaly selections are valid. Anomaly selections around surface features identified in the field notes will be removed. The processor can also add or delete any other anomaly selections that the processor feels necessary.

Anomaly Reacquisition

For towed surveys, anomalies will be identified through geophysical data analysis. Anomalies will be selected for intrusive investigation based on review of the geophysical surveys, accumulated anomaly patterns, strength of the geophysical signal, and professional judgment. A dig sheet listing all selected anomalies with their respective local and New York State Plane coordinates will be prepared for each grid surveyed. For mag and flag surveys, geophysical anomalies will be identified in the field during the survey process. Locations of confirmed anomalies will be marked with survey pin flags and recorded on a dig sheet.

The following steps will be performed to re-acquire the location of the selected anomalies:

- A geophysical reacquisition team will use an RTK system, RTS, or measuring tapes to determine the location of the anomaly from the grid corners. The ground will be painted at the measured location of the suspected anomaly.

- The geophysical reacquisition team will use a Schonstedt™ magnetometer or EM61-MK2 for reacquiring geophysical anomalies. If the anomaly is found within 1 meter of the painted location, a pin flag will be placed at the actual anomaly location. The signal response, offset distance, and direction from the re-acquired location will be noted on the dig sheet.

Anomaly reacquisition and marking procedures should be consistent with the USACE (2002) OE-005-05.01.

Instrument QC Tests

It is imperative to perform and review QC tests before carrying out production geophysical work. This ensures that the geophysical system is functioning properly and optimized for the target objectives. All instrument used in the geophysical survey should be tested in accordance with the quality control frequency specified in the USACE (2002) DID OE-005-05.01 and meet the acceptance criteria documented in this guidance. Table 24 provides the quality control frequency and acceptance criteria chart provided in the USACE (2002) guidance.

At the beginning of each day, the operator will let the instruments warm up, check the sensor positions, and check all connections including a cable shake test. Heading Error Tests will be conducted during the first day of the project for magnetometer. If equipment is replaced during the course of the site activity, the new equipment will be standardized and used to collect data over the prove-out grid. The towed array will acquire data over the prove-out grid, with the results compared with the hand-pulled system to verify the operation of the towed array system.

The six-line test will be conducted to evaluate different equipment parameters and will only need to be done once during the project for each instrument. The six-line test will be conducted to evaluate the repeatability and positional accuracy of the response amplitude of a ferrous object. The EM61-MK2 will be hand pulled between two wooden stakes placed 100 feet apart, with a marker at 50 feet. The test object will be placed at 25 feet. The operator will walk between the stakes six times and mark a fiducial at 50 feet. The first time will be with no spike object present; the operator will walk slowly the fifth time and the quickly sixth.

The six-line test will be repeated using the towed array to evaluate the repeatability and positional accuracy of the response amplitude of a ferrous object. The test object will be placed at a known location (i.e., southwest corner of the prove-out grid). The towed array will be driven over the test object six times. The first time will be with no spike object present; the operator will drive slowly the fifth time and quickly the sixth. This will allow a latency correction to be determined for the towed array.

At the beginning and end of each day, each instrument will complete a static test. This test is done by parking the instrument and collecting background data for three minutes. Subsequently a metallic object will be placed within the center of each sensor and data recorded for one minute. This procedure is repeated until data have been collected with the spike object located in each of the three sensors.

A latency test will be conducted at least twice a day by driving the array over three buried objects. The objects are arranged in a diagonal line so that when the array is driven over them in orthogonal directions, each object will pass directly underneath only a single sensor. This will allow determination of the latency value for each sensor individually. The location of these objects will be surveyed in so that the absolute positioning system can be verified by comparing the final locations of the anomalies with the known locations of the buried objects. It is expected that the anomaly peaks will be located within 1-foot of the actual buried object location.

Quality Control

Quality control will be performed during all stages of data acquisition, data processing, and target selection. The project geophysicist will be fully responsible for overseeing and documenting all QC performed with respect to the former Seneca Army Depot geophysical surveys.

Geophysical data associated with potential anomalies will be reviewed at several stages. The first quality check will be during data collection. The field crews will check the data logger to ensure that data is being collected and will examine the data during data logger "dumps" when the information is downloaded to the hard drive of a portable computer. A second quality check will be performed when the data is evaluated. If the coordinates of the data do not fall within those of the area investigated, Parsons will become aware of this when loading the data for evaluation. A final quality check will occur during the intrusive investigation, when the findings are compared against the interpretation of the geophysical data. Efforts will be made to automate the checking of the DQOs within Geosoft and the values. If the discrepancies cannot be addressed by fixing equipment or procedures in the field than a root cause analysis of the discrepancy will be generated and submitted to USACE representatives.

16.3.14.6 Data Management and Mapping

Geophysical data shall be managed in accordance with the specifications outlined in the USACE (2002) DID OE-005-05.01.

There is no digital data associated with the Schonstedt™ magnetometer; therefore, no electronic data management will be necessary for mag and flag survey.

Digital towed array survey data collected in the field will be stored electronically on field laptop or personal computers. Raw field data will be backed-up onto CD-Rs and kept separate from the CD containing the data from the day-to-day operations. This data will be stored in ASCII data files whose names will reflect the access road, sector, and homestead number. The file extension will be "xyz." A weekly back up of all data will be performed via CD.

Raw field data also will be transmitted to the USACE Geotechnical Branch within a reasonable time after it has been acquired. The data will be placed on a Seneca Army Depot FTP site as well as being transmitted on CD to the USACE. This data will be transmitted to USACE every Monday morning or the next business day if Monday falls on a holiday. The format of the raw and final processed field data from the EM61-MK2 will be in column-delineated ASCII files in the format X, Y, V1, V2, … where X = easting coordinate, Y = northing coordinate, V1 = top coil reading, and V2 = the next lower (spatially) co-located coil reading. The data will be in the New York Central State Plane coordinate system. No comment or survey line identification will be provided in the data files transmitted to USACE. The file names will reflect the sector number and grid number for the data being transmitted. A text file will be transmitted with the raw field data explaining all processing that was performed on the data and detailing any data issues identified by the geophysical field personnel. A CD that includes all data maps produced and the associated reports shall be delivered with each copy of the report.

All final mapping will be generated using GIS and provided to the USAESCH, USACE-New York, Seneca Army Depot in ESRI Arc View digital design files on a CD-ROM. All data characteristics (e.g., file naming and relationships, level structures, colors, line styles, weights) will be compiled in the design files in accordance with the surveying and mapping requirements of the Tri-Service Spatial Data Standards. Site maps plotted from these design files will be provided on reproducible drawings. The size of these drawings will be based on the information to be displayed.

The location, identification, and coordinates of the control points will be plotted on the reproducible maps (the surveyors-control points will be provided to the USACE-New York in digital format). Each map will include grid orientation to true north and magnetic north, with the differences between them shown in minutes and seconds. Grid lines or tick marks in feet and at systematic intervals will be shown with their grid values on the edges of the map. A legend showing the standard National Geodetic Survey symbols used for the mapping, a map index showing the site in relationship to all other sites within the boundary lines of the project area, a border, and a standard USACE title block also will be shown on each map.

16.3.14.7 UXO Demolition

During demolition of UXO/MPPEH and related material, safety is the primary concern. The most obvious requirements are to protect personnel, the public, and the environment from fire, blast, noise,

fragmentation, and toxic releases. Planned detonation of explosives requires more stringent safety distance requirements than those for ordnance in storage, and shall be conducted in accordance with the requirements outlined in USDoD (2004) DoD Ammunition and Explosives Safety Standards (DoD 6055.9-STD).

Control of the demolition site must be maintained during demolition operations. All personnel who are not essential to demolition operations must evacuate to a safe area. Access roads entering the blast area will be blocked outside the Maximum Generated Fragmentation Distance (MGFD) during explosive disposal operations to ensure that unsuspecting individuals are not placed in jeopardy by the explosion. The SUXOS will assure the area is clear of unauthorized personnel and equipment prior to permitting attachment of the initiation devices to the priming charge. Fragmentation distances and overpressure distances are based upon the US Army Engineering and Support Center, Huntsville (USAESCH) calculations for the MGFD presented in the Explosives Safety Submission (ESS). The calculation of fragmentation and overpressure distances is important to ensure the safety of not only site personnel but also the public. The initial fragmentation distance for this removal will be in accordance with the explosives sitting requirements set forth in the ESS. UXO/MPPEH that cannot be moved (e.g. fused or hazardous items) must be Blown In Place (BIP).

The on-site demolition shall be under the direct control of an experienced and trained UXO Technician III charged with the responsibility for all demolition activities within the area. The SUXOS shall be responsible for training all personnel regarding the nature of the materials handled, the hazards involved, and the precautions necessary and shall be present during all on-site disposal operations. The demolition team leader will maintain custody of the blasting machine or fuse igniters. The SUXOS shall ensure that the appropriate local authorities are notified prior to daily on-site demolitions.

The Parsons site manager or UXOSO will coordinate with the Seneca Army Depot Program Office upon mobilization in order to facilitate detonation reporting procedures. The UXO team and the UXOSO will evaluate the UXO and either detonate it in place (i.e. BIP) or relocate the ordnance to a designated area within the grid survey area. Detonations will occur only after all unnecessary personnel have left the area, road guards have been posted, and the required Seneca Army Depot Project Office personnel have been notified.

All of the Removal Action locations should be within the limits of Seneca Army Depot. If the Maximum Fragmentation Radius exceed the boundary of Seneca Army Depot than Engineered Controls will be used to mitigate the blast pressure and fragmentation of the disposal shot.
All demolition/disposal operations will be conducted in accordance with the Demolition SOP found in **Appendix H** of this work plan.

16.4 ENVIRONMENTAL SAMPLE COLLECTION

This section prescribes procedures for environmental sample collection activities. Decontamination shall be conducted in accordance with Section 16.3.11. For potential OE sites and sites with radioactive contamination, all any field activities should be conducted in accordance with the Generic Site-Wide Health and Safety Plan for Seneca Army Depot Activity (Parsons, 2005). Parsons pre-drilling protocol as described in Section 16.3.2 will be implemented before any drilling/excavation activity.

The construction material (e.g., plastic, PVC, metal) of the sampling devices described below shall be appropriate for the evaluation of target compounds identified for the project and shall not interfere with the chemical analyses being performed.

All purging and sampling equipment shall be decontaminated according to the specifications in Section 16.3.12 of this SAP prior to any sampling activities and shall be protected from contamination until ready for use.

16.4.1 Groundwater Sampling – Low Flow Purging and Sampling from Monitoring Well

Groundwater sampling for monitoring wells and microwells will be performed according to the Ground Water Sampling Procedure Low Stress (Low Flow) Purging and Sampling (USEPA Region 2, 1998). Low flow methods will be used to ensure collected samples are representative of groundwater conditions at the site. It should be noted that in the past high turbidities in the groundwater samples collected from monitoring wells at SEDA produced overstated groundwater results. Therefore, it is important to use low flow methods to collect groundwater samples from monitoring wells at SEDA. It should be noted that low flow sampling is not applicable in certain situations, such as bedrock wells with long open boreholes in which the water bearing zones have not been characterized. SOPs for groundwater sampling methods other than the low flow methods, if warranted, will be specified in the SS-WP.

The USEPA Region 2 (1998) recommended procedures will be implemented at the field to collect groundwater samples from monitoring wells. The USEPA Region 2 recommended procedures are presented in Appendix F and are briefed summarized below. SOPs for filtering water samples are presented in Section 16.4.12.
Unless otherwise specified in the SS-WP, groundwater samples should be collected in sequence from least to most contaminated well, whenever feasible, to minimizes the possibility of introducing contaminants into cleaner aquifers or areas.

16.4.1.1 Equipment

- Sample collection equipment (pumps, controller, safety cable, Teflon® tubing, generator, gas, polypropylene rope, buckets, graduated level etc.);
- Well construction data, location map, field data from last sampling event, sample analysis request forms;
- Reagents for sample preservation, if sample containers not pre-preserved by the laboratory;
- Appropriate sample containers;
- Ice or ice packs;
- Sample cooler;
- Monitoring instruments (PID);
- Field instrumentation for on-site measurements (e.g., pH, conductivity, dissolved oxygen, oxidation reduction potential, turbidity meters, volatile organic compound monitor);
- Appropriate field and trip blanks and analyte-free water;
- Sampling Records, Chain-of-Custody forms and sample bottle labels;
- Security lock keys;
- Tools (e.g., screw drivers, hammers, chisels, pipe wrenches with chain, tape measure);
- Electronic water level indicator;
- Pocket calculator, wristwatch/time;
- Field log book;
- Groundwater sampling record (Appendix C);
- Indelible ink marker;
- Clean plastic sheeting and 5-gallon bucket;
- Paper towels and trash bags;
- Decontamination supplies and reagents: Alconox (or equivalent), gloves (latex, nitrile, or scrub brushes equivalent), brushes; and
- Health and safety equipment.

16.4.1.2 Field Procedures

1. Planning documentation and equipment. A list of documentation and equipment is listed in the USEPA Region 2 (1998) SOP, as attached in Appendix F.

2. Decontaminate the sampling equipment. SOPs for sample tubing and submersible pump decontamination are presented in Sections 16.3.11.3 and 16.3.11.4, respectively.

3. Check the well, the lock, and the locking cap for damage or evidence of tampering. Record observations. Data regarding groundwater sample collection will be recorded on the Groundwater Sampling Record (Appendix C).

4. Place sheet of polyethylene around wellhead for placement of monitoring and sampling equipment.

5. Measure VOCs at the rim of the unopened well with a PID and record the reading.

6. Unlock protective casing and remove well cap.

7. Immediately after well cap removal, take an organic vapor reading at the rim of the opened well using a PID and record reading in the field logbook.

8. Measure water level distance from top of casing and sound the total depth as detailed below. Record in logbook (a Groundwater Elevation Report form is included in Appendix C). Check tip of water level indicator for silt or product residue (if either are observed note in logbook).

    a. Lower decontaminated water level indicator into monitoring well until indicator sounds and light is illuminated.

    b. Confirm that the water surface has been contacted by repeatedly raising and lowering the indicator at least three times to ensure a consistent sounding level has been reached.

    c. Measure and record depth (nearest 0.01 feet) to the water surface from the top of casing in field logbook. The groundwater depth should be measure to a reference point of the top casing (usually a V-cut or a permanent black mark). If the well does not have a reference point, make one.

    d. Lower the indicator to the well bottom and record the total depth.

    e. Retrieve and decontaminate water level indicator.

9. Lower decontaminated low-flow purging device (pump, safety cable, tubing and electrical lines) into well within the screened area of the well producing the highest flow rate. The pump intake should correspond to the mid-point of the most permeable zone in the screened interval. The pump intake must be kept at least two feet above the bottom of the well to prevent disturbance and resuspension of any sediment or NAPL present in the bottom of the well.

10. The water level will be measured again, with the pump in the well, before starting the pump.

11. Begin pumping at 200 to 500 milliliters per minute (ml/min) and measure the groundwater elevation approximately every five minutes to ensure that the aquifer is not being stressed. Ideally, the pump rate should cause little or no water level drawdown (drawdown of 0.3 ft or less) in the well; and, if necessary, pumping rates will be reduced to the minimum capabilities of the pump to avoid pumping the well dry and/or to ensure stabilization of indicator parameters. If significant draw down occurs, reduce the pumping rate. All development and purge water will be contained in 55-gallon drums and disposed in accordance with Section 16.3.12.

12. Observe and record: odor, color, clarity, turbidity and general water condition in logbook. Also record changes in the physical condition of the monitoring wells that could affect the well integrity. Monitor indicator parameters (Temperature, pH, turbidity, and specific conductivity of the groundwater quality) approximately every five minutes during purging of the well using calibrated instruments (see Section 6). It is anticipated that the instruments used will be the Lamotte 2020 Turbidity Meter and the Horiba U-22. The well is considered stabilized and ready for sample collection when at least one well volume has been removed and the indicator parameters have stabilized for three consecutive readings as follows:

    a. $\pm$ 0.1 for pH;
    b. $\pm$ 3% for conductivity;
    c. $\pm$ 10 mv for redox potential;
    d. $\pm$ 10% for DO; and
    e. $\pm$ 10% NTUs for turbidity with the turbidity below 50 NTU (10 NTU or below is preferred).

    If the above stabilization parameters can not be met, and all attempts have been made to minimize the drawdown, check the instrument condition and calibration, purging flow rate and all tubing connections to determine if they might be affecting the ability to achieve stable measurements. All measurements that were made during the attempt must be documented. The sampling team leader may decide whether or not to collect a sample or to continue purging after five well volumes or five volumes of the screened interval. After the monitoring well is purged, do not turn off the pump or remove it from the well. Groundwater sample collection using the low-flow method is as follows:

13. Purge the monitoring well as described previously. After purging the well, the sampling team will change to new outer gloves for sample collection.

14. The groundwater sampling order is as follows: 1) volatile organic compounds, 2) semivolatile organic compounds, 3) herbicides, 4) pesticides and PCBs, 5) explosives, 6) phenols, 7) total metals (preserved) 8) cyanide, 9) sulfate and chloride, 10) nitrate and ammonia, and 11) radionuclides. Collect groundwater samples for volatile analyses first, before any of the other parameters of interest.

The actual sampling flow rate for volatiles must be accomplished with a gradual reduction in the flow rate down to 100 milliliters per minute and such that the drawdown of the water level within the well does not exceed the maximum allowable drawdown of 0.3 ft and that hydraulic head pressure is sustained within the sampling tube to reduce aeration, bubble formation, turbulent filling of sample bottles, and loss of volatiles due to extended residence time in the tubing.

A gradual reduction in association with sustained hydraulic head pressure will minimize aeration, bubble formation, turbulent filling of sample bottles, and loss of volatiles due to extended residence time in the tubing. Hence, this coincides with the USEPA Region 2 (1998) Low-Flow Purging and Sampling Procedure and the RCRA Groundwater Monitoring Technical Enforcement Guidance Document (OSWER Directive #9950.1, September 1986), which states that when collecting samples where volatile constituents are of concern using a bladder pump, pumping rates should not exceed 100 mLs/min. If problems are encountered trying to maintain a uniform 100 mLs/min flow rate during sampling, the inside diameter (I.D.) of the sampling tube will be reduced as it reaches the well head to ensure hydraulic head pressure is maintained. A reducer coupling (0.5 inch to 0.25 inch) will be installed approximately six feet from the actual sample port. Proper fitting installation, including the use of Teflon® tape, will eliminate connection problems. VOC samples will be collected in a manner that will minimize the loss of volatile compounds and will be collected directly into pre-preserved sample containers.

In some very low-yielding formations it may not be possible to sample with minimal drawdown even using low pumping rates. It should be noted that if the water level will not stabilize at minimum pumping rates and the water level is drawn down below the top of the pump, then stabilization of the indicator parameters may not be possible. In the past, these wells have been pumped to dryness and sampled as soon as they recovered sufficiently. Approval to sample in this manner will be required from the project manager, task manager, or site manager.

15. The sample discharge for all other analytical parameters can be a continuous flow of up to 250 milliliters per minute. All sample containers should be filled with minimal turbulence by allowing the groundwater to flow from the tubing gently down the inside of the container. To decrease the sampling collection time for other parameters, a 0.5-inch coupling and tubing should replace the reducer coupling and 0.25-inch tubing. Therefore, a stoppage in flow could occur after the collection of volatile organic samples in order to change the coupling/tubing. If field filtering is required, an in-line 45-micron filter will be inserted into the sample intake line.

16. After the sample bottle is filled, the cap will be placed on the bottle and the bottle will be packaged for shipment as specified in Section 5.3.

17. Collect QA/QC samples as specified in SS-WP.

18. Measure conductivity, pH, turbidity, DO, redox potential, and temperature after sample collection and record in the field logbook.

19. Remove pump and tubing. Pump will be decontaminated for use for the next well and tubing will be discarded in accordance with Section 16.3.12.

20. Measure and record well depth.

21. Close and lock the well.

Field crews should take cautious while collecting groundwater samples to avoid contamination. A polyethylene ground cloth and 5-gallon bucket will be placed beneath all sampling equipment during well purging and sampling to prevent the spread of contaminated groundwater, and if a gas-powered generator is used to drive the pump motor or controller, the generator must be placed a minimum of 25 feet downwind of the well to limit the incidence of cross-contamination during sampling. Low flow centrifugal or bladder pumps constructed of stainless steel or Teflon® and Teflon® tubing will be used for groundwater sampling at SEDA. Each well will have its own dedicated tubing.

16.4.2 Subsurface Soil Sampling With Standard Hollow-Stem Auger Drilling Rig Equipment

This section provides procedures for subsurface soil sampling with standard hollow-stem auger drilling rig or similar device. The objective is to ensure a representative subsurface soil sample is collected at each designated sampling location.

16.4.2.1 Equipment

- Sample location map, sample analysis request forms;
- Reagents for sample preservation, if sample containers not pre-preserved by the laboratory;
- drilling rig capable to drilling to the appropriate depth;
- 4 1/4-inch or 6 1/4-inch I.D. hollow stem augers;
- Split Spoon Samples: 2-inch and/or 3-inch, 2-foot-long carbon steel split spoons;
- FID or PID (e.g., OVM);
- Folding ruler;
- Field table;
- Tin foil;
- Ball jars with lids;
- Field log book;

- Indelible ink marker;
- Overburden boring report and soil sampling record forms (Appendix C);
- Laboratory sample containers;
- Sample coolers;
- Ice or ice packs;
- Stainless steel spatula;
- Stainless steel sample bowls;
- Sampling Records, Chain-of-Custody forms and sample bottle labels;
- Clean plastic sheeting and 55-gallon drum for soil;
- Pocket calculator, wristwatch/time;
- Paper towels and trash bags;
- Decontamination supplies and reagents: Alconox (or equivalent), gloves (latex, nitrile, or scrub brushes equivalent), brushes; and
- Level D health and safety equipment as described in the site-specific Health and Safety Plan.

It should be noted that soil with low level VOCs may be sampled one of two ways, either collected in sample jar or as an EnCore™ sample (modified Method SW-846 5035). USEPA Region 2 (2001) requires the EnCore™ sampler. Unless otherwise specified by the SS-WP, three Encore samples will be collected at each location.

16.4.2.2 Field Procedures

A stainless steel split spoon sampler will be used to collect subsurface soil samples in borings using a drilling rig, using the following procedure:

1. Determine and clear (for utilities) the boring location through the depot as described in Section 16.3.2.

2. Surface materials such as vegetation may be removed from the boring location.

3. A minimum 2.5" inside diameter hollow stem auger will be used to advance the borehole to the desired subsurface depth.

   Sample depth will be specified in the SS-WP. Typically, three samples from each boring will be selected for chemical analysis: 1) 0 to 12 inches below grade; 2) immediately above the water table; and 3) between samples (1) and (2). The intermediate sample will be collected at a depth where one of the following site specific items occurs: (1) a stratigraphic change such as the base of the fill, (2) evidence of perched water table, (3) elevated PID readings, or (4) visibly affected soil

(e.g., oil stains). If none of these occur, then the intermediate sample will be collected at the halfway point between the samples collected at the surface and at the water table. If intermediate split spoon samples exhibit elevated PID readings, the one with the highest concentration will be chosen as the intermediate sample.

4. Once the desired sampling depth has been reached, a decontaminated standard three-inch diameter, two-foot long carbon steel split spoon barrel will be used to retrieve the subsurface soil sample. Split spoons of 2-inch diameter may be used only if the same interval will not be selected for chemical analysis. Immediately after the opening of a split spoon sampler the contents of the sample will be screened for VOCs and, if necessary, radiation. One to three readings will be taken along the sample with additional readings taken if additional distinctive zones are observed. These data will be recorded in the appropriate locations on the Overburden Boring Report form (Appendix C). Descriptions of the sample will also be entered on the form.

5. A new pair of clean disposable latex or nitrile gloves will be donned at each sampling location.

6. The split spoon sampler will be brought to the surface, and opened for sample collection and lithological description.

7. Collect samples to be analyzed for volatile organic compounds first in two 40 milliliter (ml) vials with septum seals. These soil samples will not be homogenized or composited during the sampling process. All VOA sample bottles will be completely filled, leaving no void space. For samples to be analyzed for other fractions, place the sample aliquot in a decontaminated stainless steel bowl, homogenized with a decontaminated stainless steel utensil using the quartering method (see below), and then fill the remaining sample containers in order of reverse volatility. Sampling information will be recorded on the Soil Sampling Record (Appendix C). This form includes information such as the sample location, number, depth, time, description, and QA/QC sample names.

8. Once the samples have been collected, they will be packaged as specified in Section 5.3.

9. QA/QC samples will be collected as specified in SS-WP.

10. Backfill the boring with the soil removed from the hole, place bentonite on the top of the backfilled hole, and restore the boring location to its original condition.

The cut and quartering technique is as follows:

The sample will be thoroughly mixed in a bowl, and divided into quarters. A portion of the soil will be gathered from two of the quartered sections. This process will be repeated until the amount of soil

needed to completely fill the sample containers has been obtained. It is very important that the soil samples be mixed as thoroughly as possible to ensure that the sample is representative of the interval sampled.

16.4.3 Surface Soil and Dry Sediment Sampling

This section provides procedures for surface soil and dry sediment sampling. Sampling representativeness should be maximized by collection of composite samples unless regulatory agencies refuse to accept composite sample data. SS-WPs should specify compositing scheme. The objective is to ensure a representative soil or sediment sample is collected at each designated sampling location.

16.4.3.1 Equipment

- Sample location map, sample analysis request forms;
- Reagents for sample preservation, if sample containers not pre-preserved by the laboratory;
- Appropriate sampling equipment (e.g., hand auger, stainless steel spoon, stainless steel spatula, stainless steel or Pyrex bowl);
- FID or PID (e.g., OVM), if warranted;
- Folding ruler;
- Field table;
- Tin foil;
- Ball jars with lids;
- Field log book;
- Indelible ink marker;
- Surface soil/sediment sampling record forms (Appendix C);
- Laboratory sample containers;
- Sample coolers;
- Ice or ice packs;
- Sampling Records, Chain-of-Custody forms and sample bottle labels;
- Clean plastic sheeting and 55-gallon drum for soil;
- Pocket calculator, wristwatch/time;
- Paper towels and trash bags;
- Decontamination supplies and reagents: Alconox (or equivalent), gloves (latex, nitrile, or scrub brushes equivalent), brushes; and
- Health and safety equipment as described in the site-specific Health and Safety Plan.

16.4.3.2 Field Procedures

Surface soil and dry sediment samples will be collected from 0 to 2 inches unless an alternate depth is specified in the SS-WP. Surface soil and dry sediment samples will be collected using either a spoon (0-2") or a hand auger (for depths greater than 2") unless otherwise specified in the SS-WP. Listed below is the process for collecting soil samples:

1. A new pair of clean disposable latex or nitrile gloves will be donned at each sampling location.

2. Prepare the sampling location by removing all vegetation, roots, etc., from the sampling point.

3. Depending upon desired sampling interval, either spoon off the sample or advance a decontaminated hand auger to the desired sampling depth below ground surface.

4. For surface samples at greater than 2" depths, remove the hand auger from the boring and use a decontaminated stainless steel spoon to remove the sample from the auger boring.

5. Place the sample into a decontaminated bowl (stainless steel or Pyrex). After the soil to be sampled has been placed in the bowl, as much organic matter (roots, leaves, worms, etc.) as possible shall be removed from the bowl.

6. Once enough sample has been collected, homogenize the sample thoroughly, using at a minimum the quartering method described in Section 16.4.2.2. When the sample has been completely mixed, fill the sample containers in reverse order according to volatility. Care will be taken to ensure that the soil placed in the bowl is not agitated extensively during this process if volatile organic analysis samples are necessary. If VOA samples are necessary, they shall be collected first. All VOA sample bottles will be completely filled, leaving no void space. Following the collection of any VOA samples, the remaining soil shall be homogenized by mixing, and the rest of the necessary samples will be collected.

7. After the sample bottles are filled, the caps will be placed on the bottles. The collected samples will be stored in a chilled cooler until they can be sent to the laboratory for analysis. The samples will be packaged for shipment as specified in Section 5.3.

8. QA/QC samples will be collected as specified in SS-WP.

9. Backfill the boring with the soil removed from the hole and return the site to its original condition to the extent possible.

Sampling information shall be recorded on the Sampling Report form for soil (Appendix C). This sheet includes information such as the sample location, number, depth, time, description, and QA/QC sample names.

16.4.4 Surface Water Sampling

This section provides the procedures for collecting surface water samples. The objective is to ensure a representative surface water sample that is collected in such a manner as to minimize the introduction of sediments into the sample is collected at each designated sampling location. If target analytes in surface water include metals, it is recommended that surface water samples be analyzed for hardness. SOPs for filtering water samples are presented in Section 16.4.12.

16.4.4.1 Equipment

- Site maps indicating the locations of samples, sample analysis request forms;
- Specialized Sampling Devices (used in atypical situations): boat for sampling ponds, lakes, and rivers, if warranted;
- Reagents for sample preservation, if sample containers not pre-preserved by the laboratory;
- Sample bottles and sample labels;
- FID or PID (e.g., OVM), if warranted;
- QA/QC: Trip blanks and extra sample sets for collection of field blanks, duplicates;
- MS/MSDs, MRD duplicates, and any other QA/QC samples;
- Coolers packed with enough ice and/or cold packs to maintain sample preservation;
- Sample Record forms and Chain-of-Custody forms;
- Field log book, surface water sampling record form (Appendix C);
- Indelible ink markers, pens;
- Pocket calculator, wristwatch/time;
- Marker flags or stakes;
- Paper towels and trash bags;
- Clean plastic sheeting and 5-gallon buckets;
- PPE: vinyl, neoprene, and/or nitrile gloves, Tyvek, Hip waders and/or waterproof boots, Level C equipment if necessary;
- Deionized/Distilled water, paper towels, and trash bags;
- Folding ruler;
- Decontamination supplies and reagents: Alconox (or equivalent), gloves (latex, nitrile, or scrub brushes equivalent), brushes;
- Field instrumentation for on-site measurements (e.g., pH, conductivity, dissolved oxygen, oxidation reduction potential, turbidity meters, volatile organic compound monitor); and

- Health and safety equipment as described in the site-specific Health and Safety Plan.

16.4.4.2 Field Procedures

The surface water sample collection location should be deep enough so the sample bottles can be completely submerged (if possible), in an area with minimal flow or surface disturbance, and free of suspended material. Downstream samples will be collected first and disturbances during wading should be avoided. Time for surface water and sediment sampling will be specified in the SS-WP. Usually the sampling will occur during high flow conditions (i.e., after a rain event) to assure sufficient water supply and to sample site stormwater runoff. At locations where both surface water and sediments will be collected, the surface water samples should be collected before sediment samples. The process for collecting surface water samples is as follows:

1. Prior to sampling at any surface water/sediment location, the direction of actual surface water flow directions shall be noted and recorded on a site map. The flow direction shall also be compared to the flow directions expected at the site to ensure that the samples planned for the downstream direction are truly at a downstream location.

2. A new pair of clean disposable latex or nitrile gloves will be donned at each sampling location.

3. Before the surface water samples are collected at each location, measurements of temperature, pH, specific conductance, turbidity, and oxidation-reduction potential (ORP) shall be taken by direct immersion of instrument probes into the water body. If direct measurement is not possible, these measurements shall be taken from water collected and placed in a field container. If this procedure is followed, the water used to analyze field parameters shall not be used as the sample water; another sample will be collected.

4. Facing upstream, submerge pre-labeled sample bottles in the upright position to prevent the loss of preservative into the water. Sediment should not be disturbed during the collection of surface water samples.

5. Allow sample bottle to fill and use bottle cap if necessary to fill the bottle completely. If samples cannot be collected directly into the sample bottle, a decontaminated sample collection device made of glass, stainless steel, or Teflon® (e.g., a bailer) may be used.

6. After the sample bottle is filled, the cap will be placed on the bottle and the samples will be packed in an ice-filled cooler immediately after sampling. The samples will be packaged for shipment as specified in Section 5.3.

7. Conductivity, pH, turbidity, and temperature, will be measured after sample collection. The measurements will be recorded in the field logbook. All pertinent field data will be recorded on the Sampling Record for Surface Water (Appendix C).

8. QA/QC samples will be collected as specified in SS-WP.

9. If filtered samples are required, a Grundfos pump will be used to pull the sample through an in-line 45-micron filter. The sample will be drawn directly from the surface water body, or from a sample aliquot collected into a laboratory-supplied, preservative-free sample bottle. The sample will be discharged from the filter line outlet directly into laboratory-supplied pre-preserved sample bottles. Alternate methods, if used, will be described in the SS-WP.

16.4.5 Wet Sediment Sampling

Sediment samples should be collected from background or furthest from the source locations first, to minimize the possibility of cross-contamination. Thereafter, the most downstream sediment samples will be collected followed by the next upstream samples. If surface water samples are to be taken at the same location, they should be collected before the sediment samples.

Unless specified in the SS-WP, sediment sample shall be collected within 6 inches into the sediments. The Sampling Record form for surface water (Appendix C) can be used to record all pertinent information. The description will be recorded according to the procedures outlined in Section 16.3.1. The addition of organic matter into the sediment samples should be avoided.

16.4.5.1 Equipment

- Site maps indicating the locations of samples, sample analysis request forms
- Specialized Sampling Devices (used in atypical situations): boat for sampling ponds, lakes, and rivers, if warranted, Stainless steel pitcher (clamped to a telescoping aluminum pole when necessary), Sediment dredge, such as a Ponar sampler, for deep sediment samples, Decontaminated stainless steel bowls and spoons;
- Reagents for sample preservation, if sample containers not pre-preserved by the laboratory
- Sample bottles and sample labels;
- FID or PID (e.g., OVM), if warranted;
- QA/QC: Trip blanks and extra sample sets for collection of field blanks, duplicates;
- MS/MSDs, MRD duplicates, and any other QA/QC samples;
- Coolers packed with enough ice and/or cold packs to maintain sample preservation;
- Sample Record forms and Chain-of-Custody forms;

- Field log book, surface water sampling record form (Appendix C);
- Indelible ink markers, pens;
- Pocket calculator, wristwatch/time;
- Marker flags or stakes;
- Paper towels and trash bags;
- Clean plastic sheeting and 5-gallon buckets;
- PPE: vinyl, neoprene, and/or nitrile gloves, Tyvek, Hip waders and/or waterproof boots, Level C equipment if necessary;
- Deionized/Distilled water, paper towels, and trash bags;
- Folding ruler;
- Decontamination supplies and reagents: Alconox (or equivalent), gloves (latex, nitrile, or scrub brushes equivalent), brushes;
- Field instrumentation for on-site measurements (e.g., pH, conductivity, dissolved oxygen, oxidation reduction potential, turbidity meters, volatile organic compound monitor); and
- Health and safety equipment as described in the site-specific Health and Safety Plan.

16.4.5.2 Field Procedures

The process for collecting sediment samples is as follows:

1. A new pair of clean disposable latex or nitrile gloves will be donned at each sampling location.

2. In shallow streams and ditches that allow wading, sediment samples will be collected by using a decontaminated stainless steel spoon or scoop. In areas where wading is not possible, a hand auger or scoop attached to a pole may be needed to collect sediment samples.

3. While facing upstream, collect the sample by scooping along the bottom of the surface water body. Remove excess water and place the sediment sample into a decontaminated stainless steel bowl.

4. After a sufficient sample volume has been collected into the stainless steel bowl, the sample will be homogenized using the quartering method and then placed into the appropriate sample bottle. If volatile organic analysis samples are required at the site, these shall be collected first, prior to any mixing of the sediment. The rest of the samples will be collected after the remaining sediments in the bowl have been stirred for homogenization purposes.

5. After the sample bottle is filled, the cap will be placed on the bottle and the sediment samples will be stored in an ice-filled cooler immediately after sampling is complete. The samples will be packaged for shipment as specified in Section 5.3.

6. QA/QC samples will be collected as specified in the SS-WP.

16.4.6 Soil Gas Sampling

This section presents the general information on soil gas sampling. If soil gas sampling is warranted for specific site, detailed SOPs will be presented in the SS-WP.

Soil gas may be sampled using commercially available soil gas sampling probes, a gas tight syringe or bulb, a SUMMA® canister, sorbent tubes, or a Tedlar® bag.

When soil gas samples are collected using commercially available soil gas sampling probes, the probes are connected to a steel drive shaft used to push the probe to the desired sampling depth. The sampling container shall be a glass or metal bulb equipped with an entrance and exit spigot. The Tygon® or Teflon® tubing (as specified in the SS-WP) from the sampling probe shall be attached to the entrance spigot, and a second length of tubing shall run from the exit spigot of the bulb to a portable vacuum pump. At each sample location, the sampling probes shall be driven to a previously determined depth of between 5 to 10 feet below ground surface. When the probe is at the desired depth, the steel drive shaft shall be pulled back slightly, exposing the gas intakes on the sample probe. The vacuum pump shall then be switched on, drawing the gas contained in the interstitial spaces of the soil through the probe, tubing, and sample container. The purge volume should be equal to the sum of the volumes of the tubing and the space below the drive rod when the rod is pulled up. For example, with 10 feet of 1/8-inch tubing and a 1-inch space below the drive rod, approximately 42 mL would need to be purged. This can easily be done with a 60 mL syringe and a stainless steel three-way valve. After the appropriate purge volume of gas have been drawn, the Tygon® or Teflon® tubing shall be clamped shut on the downstream side of the bulb (toward the pump) and then the upstream side of the bulb. The vacuum pump shall then be switched off. The volume of 2 liters shall ensure that the gas in the glass bulb originated from the soil interstitial space, rather than the tubing, so long as a reasonably short tubing length is used. Following sample collection, the sample container shall be labeled and the sample number recorded in the field log book along with the following information: soil gas sample or probe depth, apparent moisture content (dry, moist, saturated) of the sampled zone, if available, soil gas purge rate, sampling duration, sampling system leak rate, and pump vacuum, description of sample containers, location of sample analysis, location and grid layout of sampling stations.

Gas tight syringe or bulb samples are collected for on-site laboratory analyses. To collect a syringe sample, a fitting with a Teflon® septum shall be installed in the sampling line ahead of the purge pump. After purging the required volume, samples are collected. Bulb samples are collected using a manifold configuration.

SUMMA® Canister samples are collected for off-site laboratory analyses. A fitting for attaching the canister shall be installed in the sampling line ahead of the purge pump. Prior to sampling, the initial canister vacuum is measured, the canister is attached to the sample line, and the probe, etc. is purged. The canister sample is then collected.

Sorbent tubes may be used to collect samples for real-time field analysis (i.e., colorimetric tubes such as Draeger tubes) or for off-site laboratory analyses. The well or probe is purged, the sorbent tube is installed in the sampling line, and the required volume of soil gas is drawn through the tube. Colorimetric tubes are read directly, while sorbent tubes are capped and stored on ice (dry ice may be required) until being shipped to the laboratory.

Tedlar® bag samples can be collected for field analysis using real-time instruments or for off-site laboratory analysis. An oiless diaphragm pump is attached to the sampling line and a Tedlar® bag is attached to the pump exhaust. Samples shall be kept out of direct light and analyzed within 24 hours of collection to minimize the potential for loss, reaction, or degradation of VOCs. If Tedlar® bags are used, a blank bag sample should also be collected for each lot of bags used. The blank bag sample should be filled with pure nitrogen and submitted as a field blank. Cautions should be exercised when using Tedlar® bags as they can contain trace amounts of compounds, particularly petroleum hydrocarbons.

No matter what methods will be used to collect soil gas samples, cautions need to be exercised to prevent ambient air intrusion into the sample. Different measures shall be taken based on the specific project objective. All samples for inclusion in a risk assessment should include the following steps to prevent ambient air intrusion:

- Packing a hydrated bentonite seal around the probe at the ground surface;

- Conducting a leak test to make sure there are no leaks in the sampling train. Use a syringe to pull a vacuum prior to pulling up on the drive rod. If the vacuum is present, there are no leaks;

- Limiting the purge and sampling rate to no more than 200 mL per minute. In addition to increasing the chance for ambient air infiltration, higher rates can cause biased high concentrations by "stripping" contaminants adsorbed to soil particles. It is recommended that all purging (and sampling for Tedlar Bags) be done with a syringe to minimize the purge rate. The sampling rate should be similar to the purge rate. Flow regulators may be required to limit the sampling rate of summa canisters;

- It is recommended that a tracer compound be used to test for ambient air intrusion. The draft New York State Department of Health guidance (Guidance for Evaluating Soil Vapor Intrusion in the

State of New York, Public Comment Draft, February 2005), recommends using a gas, such as helium or butane as a tracer. Another easier method is to use rubbing alcohol (2-propanol). Paper towels can be soaked with 2-propanol and place around the base of the drive rod, around the tubing where it exits the drive rod, and at any other connections or fittings. The 2-propanol will volatilize and will be detected in the sample at a high concentration if ambient air infiltration is significant.

In addition to the information listed in Section 16.6, the following information shall be recorded. If only qualitative data are required, only items 1 and 6 are needed: (1) soil gas sample or probe depth, (2) apparent moisture content (dry, moist, saturated) of the sampled zone, (3) soil gas purge rate, sampling duration, sampling system leak rate, and pump vacuum, (4) description of sample containers (if any), (5) location of sample analysis, (6) location and grid layout of sampling stations, (7) instrument calibration.

16.4.7 Composite Sampling

Occasionally, samples will be composited prior to chemical or physical characterization. Composites will be collected in the following steps:

- Discrete subsamples of equivalent size (weight, volume) will be collected from each of the selected locations and combined in a common receptacle;

- All necessary sample preparative operations (e.g., sample filtration, sleeve screening) will be performed on the subsamples in the receptacle;

- The material remaining after preparation will then be fully homogenized, generally by mixing;

- Any necessary preservatives will be added;

- The required samples will be collected and placed into clean sample bottles and packaged for shipment;

- Samples collected for certain types of analyses (volatile organic compounds and sulfides) WILL NOT be composited unless compositing is specifically requested by a regulatory agency.

16.4.8 Confirmatory Sampling

Confirmatory soil sampling will be conducted at each site where excavations or removal of piles or berm structures are performed. The goal of the confirmatory sampling is to provide data that verifies that the identified contamination has been removed, and that concentrations of contaminants remaining

at the subject site comply with documented cleanup objectives established by the Army. If the results obtained from the analysis of confirmatory soil samples verify that the Army's cleanup objectives have been obtained, no further excavation will be conducted at the subject site. If the analytical results for the confirmatory samples do not verify that the Army's cleanup objectives have been obtained, further excavation will be conducted until such verification is provided.

16.4.8.1 Equipment

- Field Book and Project Plans;
- Sample Labels;
- Shipping Labels;
- Sample Records;
- Shipping Forms;
- Chain-of-Custody Forms;
- Camera;
- Photo-ionization Detector;
- Personal Protective Equipment in accordance with the Health and Safety Plan;
- Marker stakes, flagging and paint;
- Tape Measure;
- Decontamination Supplies;
- Inert (e.g., stainless steel or Teflon®) sampling equipment;
- Hand Auger;
- Mixing Bowls;
- Pre-cleaned Sample Bottles;
- Plastic Sheeting;
- Shipping Tape;
- Ice Chests and Ice (for sample transport).

16.4.8.2 Number, Frequency, and Location of Confirmatory Sampling

Number, frequency, and location of confirmatory samples will be specified in the SS-WP. This section provides some general requirement for confirmatory sampling.

Confirmatory soil samples will be collected from the base and sidewalls of each excavation, except in the circumstance where the depth of the excavation measures 12 inches or less. In situations where the sidewalls of an excavation are 12 inches or less in depth, sidewall samples will not be collected, but will be replaced by confirmatory samples that are collected outside the perimeter of the excavation.

Confirmatory samples will also be collected from locations beneath and around every aboveground soil pile or berm structure that is removed.

At least one discrete sample will be collected from each face of an open excavation that is 12 inches in depth or greater. Thus, a minimum of five confirmatory samples (i.e., one base, and four sidewall samples) will be collected at each excavation. Additional confirmatory samples will be collected at a rate of one per every 2,500 square feet of surface area, or fraction thereof, found on an exposed excavation face.

For excavations where the depth of the excavation is less than or equal to one foot below grade, confirmatory samples will be collected from the perimeter of the excavation at a rate of no less than one sample per every 100 linear feet of length on each edge of the excavation. A minimum of one sample will be collected along each edge of the excavation. Additionally, at least one sample will be collected from the base of the excavation, and additional samples will be collected from the base of the excavation at a rate of one per every additional 2,500 square feet or less of surface area.

For aboveground soil piles or berm structures that are removed, at least one sample will be collected from a point that is directly beneath each pile or berm structure, and from at least four other locations (e.g., major compass point locations) that are located around the perimeter of the pile or berm. Additional samples from beneath the pile will be collected at a rate of not less that one per every 2,500 square feet or less of surface area underlying the pile or berm, and at a rate of at least one per every 100 linear feet of the piles or berms perimeter.

Locations of confirmatory sampling will be biased towards areas that are most likely to be contaminated. Visual and olfactory sensing and use of portable field monitoring devices (e.g., photo-ionization detectors) should be used, within the bounds of the site-specific health and safety plan and good operating procedures, to assist in the selection of confirmatory sampling locations.

Additional confirmatory samples should be collected an analyzed, as may be needed, based on results of field screening and observations, or based on professional judgment.

16.4.8.2 Field Procedures

1. Once the excavation is complete, a drawing of the completed excavation will be prepared and necessary measurements shall be recorded in the field notes. Specific measurements collected will include the length, width, and depth (if subsurface excavation) of the excavation. The depth of the excavation will be reported at each corner, and at intermediate locations that are no further than 100 feet apart. These measurements will be used to document that sufficient samples have been

collected from the excavation to reasonably assess whether residual contamination remains in the area of the excavation.

2. Once the drawing of the excavation is prepared, all proposed sampling locations will be marked and labeled and information describing the location of each proposed sampling location will be transcribed into the field notes and onto site maps. Each sampling location must be uniquely identified with a sample location.

3. Confirmatory samples will be collected from a depth of not less than one-inch below the excavation's surface and not more than six inches below the excavation's surface. The one-inch minimum is recommended to ensure that soils exposed directly to the atmosphere, which could result in the off-gassing of volatile organic or inorganic (e.g., sulfide or cyanide) compounds and a decreased level of volatile content over time, are not collected and used for the volatile compound analyses. The depth from which confirmatory samples are obtained will be recorded in the field notes at the time of collection.

4. At the time of their collection, confirmatory soil samples will be visually described for:
   a. Soil type,
   b. Color,
   c. Moisture content,
   d. Texture,
   e. Grain size and shape,
   f. Consistency,
   g. Visible evidence of staining or discoloration, and
   h. Any other observations (e.g., odors).

5. All data collected at the time of sample collection will be transcribed into the field records. The identity of the sampler, the date and time of sample collection, the location of the sample collection (i.e., location id), the identity of the sample (i.e., sample number), a description of the sampling method (e.g., auger, trowel, spade, homogenized, etc.) used, the number of sample containers collected, and the intended analysis that will be completed will be recorded.

6. All sampling will be completed using decontaminated, inert (e.g., stainless steel, Teflon®, etc.) sampling equipment. Selected sampling equipment may be used for all collection activities conducted at one location (e.g., the sample and its duplicate for all required analyses) during one contiguous time period; however, once the equipment has been used at one location, it can not be used at another location until it has been thoroughly decontaminated per prescribed procedures.

7. Samples collected for volatile compound analyses (e.g., volatile organic compounds or cyanide) will be collected first and will be transferred directly from the ground to the appropriate sample container (e.g., EnCore™). Samples for volatile compound analyses will not be homogenized. Samples collected for non-volatile analyses (e.g., semivolatile organic compounds, pesticides, metals, nitrate, total organic carbon (TOC), total petroleum hydrocarbon (TPH)) should be collected and transferred to an inert mixing bowl and homogenized prior to being placed into their final sample bottles.

8. A recommended order for sample collection is provided below:

Collected without homogenization
Volatile Organic Compound
Volatile Inorganic Compounds (cyanide, sulfide, nitrite, etc.)

Collected, homogenized, and split into required bottles
Semivolatile Organic Compounds
Pesticides/PCBs
Herbicides
Explosives
Total Petroleum Hydrocarbons
Total Organic Carbon
Metals
Anionic Species (Chloride, Sulfate, Nitrate, etc.)

16.4.9 Air Sampling

This section presents methods of collecting air samples for metal analysis and SVOC analysis. All other air sampling programs, if warranted for specific site, shall be specified with detailed SOPs in the SS-WP.

Metals

This section covers three methods to collect air samples for metals - one for gaseous phase mercury, one for lead in airborne particulate, and the third for all other target metals in airborne particulate. All other analyses, if warranted, will be presented in the SS-WP.

Air samples for gaseous phase mercury will be obtained using National Institute for Occupational Safety and Health (NIOSH) Method 6009, which employs the use of a personal sampling pump to draw sample air through a glass sorbent tube. Sample air is drawn through the tube at a constant known flow rate between 0.15 to 0.25 liters per minute for a total sample size between 2 and 100 liters. The exposed tubes

were then sealed and sent to an environmental analytical laboratory for mercury analysis. A copy of the method is attached in Appendix F.

Air samples for airborne particulate phase lead will be collected using NIOSH Method 7082, which employs the use of a personal sampling pump to draw sample air through a cellulose easter filter (0.8µm). Sample air is drawn through the filter at a constant known flow rate between 1 and 4 L/min for up to 8 hours for a total sample size of 2000 to 1500 liters for time-weighted average measurements. The exposed filter were then sealed and sent to an environmental analytical laboratory for analysis for lead. A copy of the method is attached in Appendix F.

Air samples for all other target metals will be obtained by the USEPA reference method for determination of the particulate matter less than 10µm aerodynamic diameter (PM_{10}) concentrations in air, as published in 67 Fed. Reg.,15566, April 2, 2002. This standard high-volume particulate sampling method RFPS–0202–141, titled ‘‘Tisch Environmental Model TE–6070 PM10 High-Volume Air Sampler,’’ consists of a TE–6070 PM10 size selective inlet, 8″ x 10″ filter holder, aluminum outdoor shelter, mass flow controller or volumetric flow controller with brush or brushless motor, seven day mechanical off/on-elapsed timer or 11 day digital off/on-elapsed timer, and any of the high volume sampler variants identified as TE– 6070–BL, TE–6070D, TE–6070D–BL, TE– 6070V, TE–6070V–BL, TE–6070–DV, or TE– 6070DV–BL, with or without the optional stainless steel filter media holder/filter cartridge or continuous flow/pressure recorder. An operations manual is attached in Appendix G. Metal concentrations in air can be derived by multiplying metal concentration in PM_{10} and PM_{10} concentration in air with appropriate unit conversion.

Semivolatile Organic Compounds

Air samples for SVOCs will be obtained by using Method TO-13 (USEPA, 1999), which utilizes a modified high-volume sampler in conjunction with a particulate filter and a combination of XAD-2 resin and polyurethane foam (PUF) adsorbent in a glass cartridge. The low level of SVOCs in the air requires the use of a relatively high-volume sampling technique to acquire sufficient sample for analysis.
The sample collection media for SVOCs consisted of a filter (for particulate phase SVOCs) followed by an adsorbent glass cartridge filled with PUF/XAD/PUF (for gaseous phase SVOCs).

16.4.10 Wipe Sampling

This section presents protocols for wipe sampling that may be necessary within buildings. This section presents the wipe sampling SOP that can be used to collect wall, roof, and other surface samples.

16.4.10.1 Equipment

- Field Book and Project Plans;
- Sample Labels;
- Shipping Labels;
- Sample Records;
- Shipping Forms;
- Chain-of-Custody Forms;
- Camera;
- Indelible ink markers, pens;
- Personal Protective Equipment in accordance with the Health and Safety Plan;
- Marker stakes, flagging and paint, yellow ribbon;
- Tape Measures;
- Decontamination Supplies, Alconox (or equivalent), brushes;
- Gloves (latex, nitrile, or scrub brushes equivalent);
- 3-inch by 3-inch cotton gauze pads presoaked with appropriate solvent (as specified in the SS-WP);
- Decontaminated pair of tweezers or forceps;
- Decontaminated wipe template;
- Pre-cleaned sample bottles (Teflon®, stainless steel, or glass);
- Plastic sheeting and paper towels;
- Shipping tape and clear tape;
- Trash bag, storage container for contaminated sampling equipment;
- Ice Chests and Ice (for sample transport).

16.4.10.2 Field Procedures

1. Assemble all equipment necessary for wipe sample collection prior to leaving the office.

2. Identify and mark and exclusion zone with yellow ribbon to keep unauthorized personnel from entering the area where the work will be performed.

3. Identify and mark an external limited access zone where sampling equipment can be placed, once it has been used, pending decontamination and recycle. If field decontamination of sampling equipment is a planned event, necessary decontamination reagents and supplies should be placed in this area prior to sample collection. If field decontamination is not planned, used sampling equipment should be placed into a polyethylene bag and a transport container after it is used.

4. Identify and record specific descriptive details for one or more locations that will be used as reference points for positioning all wipe samples. Suitable locations may include lower right hand corner of an entry doorway, the northeastern corner of the enclosure or pad. Photograph each reference point, and record sufficient pertinent information within field sampling documentation that will allow future reviewers to recreate the sampling event.

5. Locate the approximate area of the proposed sampling points using a tape measure and facility map. Mask off an area that is larger than the proposed sampling area (10 centimeters (cm) by 10 cm – 100 cm^2) and annotate the sample site identification on a piece of tape that is placed outside of the area to be sampled. Photograph each sampling location and the overall sampling grid and record details of the site within the field documentation.

6. Don protective gloves and prepare needed 3-inch by 3-inch cotton gauze pads. The gauze pad should only be touched using a decontaminated pair of tweezers or forceps. Do not touch the gauze with bare or gloved hands as dirt and oils from your skin or the surface of the gloves may contaminate the samples. Similarly, do not let the gauze pad touch any surfaces that may be contaminated. Place the gauze pad in a clean, resealable sample vial. The sample vial should be constructed of inert materials (i.e., Teflon®, stainless steel, or glass) and contain no materials (e.g., waxed sealing lids) that could contaminate the sample.

7. Soak each needed 3-inch by 3-inch cotton gauze pads with 15 to 20 milliliters each of an appropriate solvent (as designated in the SS-WP). Reseal the sample vial and place in a secure stand or container pending use.

8. Assemble all equipment needed for the collection of a wipe sample at one location and move it to the first sampling location.

9. Don a new pair of disposable gloves. Use a respirator equipped with an organic vapor cartridge if the sample collection and preparation will be completed in an area that is not well ventilated.

10. Inspect the area to be wiped and select a location where the wipe template will be placed. Place and tape an inert, decontaminated, wipe template over the selected sampling site. The tape must be kept exterior to the surface that will be wiped. Adhesive from the tape should not contact the surface within the wiping area as it may contaminate the sample. Do not touch the surface to be wiped with gloved hands. Tape and gloving materials can be a significant source of organic compounds such as phthalates which will contaminate the samples.

11. Open the sealed sample vial containing the pre-soaked gauze pad, and remove the pad using a decontaminated pair of forceps. All subsequent wiping motions should be done in a manner that

ensures that all chemical materials recovered from the surface are concentrated on one side of the gauze.

12. Collect the sample by applying uniform pressure to the wipe pad as it is drawn with straight, even strokes, over the area to be wiped. Successive strokes used should overlap slightly to ensure that the entire are is wiped. The first sequence of strokes should be conducted from left to right, moving from the top of the sampling square to the bottom of the sampling square.

13. Once the first sequence of wiping repetitions is completed, the entire square must be wiped a second time with the same pad in a direction that is perpendicular to the first wiping pattern. Therefore, start at the upper left hand corner of the sampling square and wipe moving towards the right. Start each subsequent pass at the left side of the sampling template at a location below but overlapping the previous pass and move successively to the right and down until the entire square is wiped a second time.

14. Let the gauze air dry.

15. Fold the dry gauze so the sampling side is inwards and place it in the pre-cleaned sample vial using the forceps. Again, gloved hands and tape should not be allowed to contact the gauze as they will contaminate the sample.

16. Inspect the area just wiped. If the surface still appears to contain residue, use additional pre-soaked gauze pads to complete additional repetitions of steps 11 through 15, above. Each selected surface must be wiped until no residue is observed to remain at the site. Each successive gauze pad should be used for only one vertical and horizontal wiping sequence as is described above. Place all additional gauze pads used at one sampling location in the same initial sampling vial.

17. Cap the sample vial containing the used gauze pads.

18. Label the sample vial with a unique sample code, information on the sampling site, the date/time of collection and the personnel responsible for the sample collection.

19. Place the sample vial in an ice chest that is packed with ice. A sample temperature of 4°C ± 2°C must be achieved and maintained during storage.

20. Remove the template and the tape from the surface and remove all tape. Place tape in a trash bag that will subsequently be designated for appropriate disposal. Place all used sampling equipment in a container that will be used to transport it to the point of decontamination.

21. Remove and discard gloves in the trash bag.

22. Label the sample vial and document the sample collection process in the field book.

23. Decontaminate all sampling equipment before reuse at another site. All sampling equipment should be decontaminated using pesticide grade hexane. Let equipment air dry and wrap securely in clean aluminum foil pending use at another site.

24. Complete chain-of-custody forms and pack samples for shipment to the laboratory. The samples should be pack on ice and maintained at 4°C ± 2°C until delivered to the laboratory.

16.4.10.3 Quality Assurance and Quality Control Samples

Field/Ambient Blank – Prepare gauze with solvent as described in procedure above, but do not use to wipe a surface. Allow to air dry, fold, and place in sample vial. Label, record collection details in field book and enter on chain of custody. Ship to laboratory for analysis.

Duplicate – Wipe two adjacent areas at the same sampling location following procedures defined above. Separate equipment must be used. The sample and duplicate pair should be collected from areas that appear to be identical. During sample collection operations, ensure that the sampling activities completed for the first sample do not contaminate the area designated for the collection of the duplicate. Ensure that tape and discarded materials do not impact the adjacent sites.

Trip Blank – To be collected for all media. Trip blank to be supplied by the analytical laboratory and be shipped to and returned to the laboratory with the sampling equipment.

One sample duplicate and a field blank must be collected for each SDG of 20 field samples or less. A trip blank should accompany each shipment of field samples sent to the laboratory. All sampling equipment and samples should be stored and packaged in an equivalent manner during their time in the field.

16.4.10.4 RINSATE SAMPLE COLLECTION PROTOCOL

This procedure is to be used to obtain representative samples for analysis from concrete floors, secondary containment areas and sumps, including surfaces that have been coated, to establish whether or not there is any contamination on the concrete surfaces. This procedure is to be performed after the

surfaces have been cleaned and decontaminated, usually pursuant to the approved Closure Plan[1]. This procedure may also be suitable for use on other surfaces on a case-by-case basis.

1. Create an exclusion zone with colored (e.g., yellow) ribbon to keep extraneous personnel from entering area.

2. Sketch the area to be sampled. Sketches should include locations of building columns, walls, fixed equipment, and the proposed rinsate sampling locations themselves (to accurately locate the rinsate sampling points within the buildings) for Department concurrence. The sample locations must be chosen to include any areas of staining, discoloration or other evidence of spills. The sample locations will be approved by a NYSDEC staff person usually onsite on the day of sampling (unless NYSDEC chooses not to be present or states that such approval is not needed). Each sample location should be approximately 2500cm^2 (say 50cm by 50cm) or 400in^2 (say 20in by 20 in), but size may be adjusted to the extent necessary to accommodate field conditions with NYSDEC approval.

3. Assemble and clean all equipment necessary for sample collection. Equipment needs to be cleaned, if not already pre-cleaned by the laboratory.

4. Create a temporary containment area on the storage zone floor using an inert, clean or cleaned, flexible boom (e.g., water filled polyethylene tube, nonabsorbent spill containment berm), if necessary. If the floor is relatively level and water will puddle without flowing out of the sample location, a boom may not be not necessary.

5. Label the sample containers with a unique sample code, information on the site, sample locations and the date and time samples were collected. Affix appropriate labels for test parameters on the sample containers. Put on a new pair of disposable nitrile gloves.

6. De-ionized water is to be used for this protocol. The de-ionized water may be provided by the laboratory. For each sampling location, start with two liters or 2 quarts of de-ionized water to allow for the collection of a sufficient sample size for all of parameters to be tested for, as specified by the laboratory, including QC samples. If necessary, additional de-ionized water may be used, but no more than the minimum amount needed to provide a sufficient sample size. Record the temperature of the room and of the de-ionized water. At each sampling location, slowly pour the de-ionized water onto the surface to be sampled. A clean/cleaned wash bottle may be utilized to

[1] A detailed washing and rinsing (i.e., decontamination) procedure, as approved by the regulators, will be followed based upon the selected technology. USEPA (1985) Guide for Decontaminating Buildings, Structures, and Equipment at Superfund Sites or its most recent update can be used to develop such technology.

cover the area uniformly with the de-ionized water. If the individual area is sloped, start pouring at the highest elevation. Record the volume of de-ionized water used for each sample location.

7. Allow de-ionized water to collect and remain in the sample location for 10 minutes.

8. For each sampling location, collect the number and type of samples as specified in the closure plan along with appropriate QA/QC samples. Samples shall be collected using dedicated, sterile glass pipettes provided by the laboratory. The pipettes will be used to transfer the sample fluids into the appropriate bottles provided by the laboratory. Volatile sample bottles shall be filled first to minimize loss of volatiles. Record the volume of water collected for each sample for each sample location.

9. Samples must not be composited.

10. Cap the sample containers and place them in a laboratory cooler with ice to maintain a temperature of 4 ^{o}C.

11. Measure the exact wetted area for each sampling location sampled using a tape measure or other suitable device. Place all measurements and the sketch of the area in the site field book. Measurements should include all appropriate or unusual conditions observed while collecting each sample (i.e., drainage patterns followed, stained areas present, condition of storage zone floor, etc.).

12. Remove and discard the gloves. Place all disposable gloves into a plastic bag designated for proper disposal.

13. Enter information on procedures followed including details of samples and sampling in the field book. Photographs of the sample locations, wetted areas, equipment, and actual sampling events may be taken by the facility or Department staff and a list of the photographs shall be recorded in the field book.

14. Fill out chain-of-custody forms. Prepare the samples for storage and shipping in laboratory cooler with sufficient ice to maintain a temperature of 4 ^{o}C. Ship overnight to the laboratory for analysis.

15. Follow chain-of custody procedures as detailed in the Quality Assurance Program Plan.

16. Analytical Methods

    All of the samples need to be analyzed by a laboratory certified by NYSDOH ELAP for the parameters of interest. The following preparation and analytical methods may be used.

PARAMETER	PREPARATION*	ANALYSIS
TCL Volatiles	Method 5030	Method 8260
TCL Semi- Volatiles	Method 3640	Method 8270
Pesticides	Method 3620	Method 8081
TAL Metals	Method 3010/3015/3020 as appropriate	Method 6010 and 7000 series as appropriate

* Preparation Methods should be used where appropriate, prior to analysis

17. Target Detection Limits and QA/QC

    The target detection limits for TCL volatiles and TCL semi-volatiles is 5ug/L. The target detection limits for the metals is as per the table from the NYSDEC ASP.

    The quality control results shall be submitted along with the sample results. This QC data shall include surrogate recoveries, MS/MSD percent recoveries, internal standard area counts and retention times (as applicable), and blank results for the organics. For the metals, submit CRQL standard for Atomic Absorption (AA) and ICP, spike sample recovery, duplicates, blanks, ICP interference check sample, post digestion spike sample recoveries (if applicable), laboratory control sample results, and ICP serial dilution results. The QC analysis should be performed on site specific samples. The QA/QC requirements of SW-846 shall be met.

18. Clean closure criteria

    The sample results for the rinsate samples shall be compared to the New York State Water Quality Standards for Class GA groundwater, 6 NYCRR Part 703.5 which are available at www.dec.state.ny.us/website/regs/703.htm.

16.4.11 Radiological Surveys

This section presents general information for several common types of radiological surveys that may be required at SEDA. Surveys may be required during the remedial process to determine that all suspected radioactive contamination in an area, if present, has been removed, and to assess and minimize worker exposure if a radiological hazard is present. All field personnel performing radiological surveys should receive a minimum 1-hour of radiological safety and fundamental training, as well as a minimum of 24 hours of onsite orientation and technique training. This will include a briefing on the potential risks associated with radiological contaminants. All radiation survey work onsite will be overseen by a HP/RSO. All work will be conducted in accordance with the Generic Site-Wide Health and Safety Plan for Seneca Army Depot Activity (Parsons, 2005). Site-specific sampling and measurement plans,

DQOs, and site release criteria will be developed as necessary using the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM; USEPA, USNRC, USDoE, USDoD, 2001), instrument and survey-specific SOPs, and other applicable federal and state guidance.

16.4.11.1 Gamma Radiation Surveys

Surveys for gamma radiation are commonly performed with sodium iodide (NaI) based scintillation detectors. General surveys, and surveys for higher energy radionuclides, are performed with detectors with larger (e.g., 2" by 2") crystals, while surveys for lower energy gamma radiation and x-rays may be performed using smaller crystals, such as the crystal in a FIDLER detector. Gamma radiation may be measured in units of counts per minute (cpm), and in some cases measurements may be correlated with a soil or volumetric concentration in units of picocuries per gram (pCi/g). In addition, some gamma instruments report an exposure rate, which can be used to monitor worker exposure.

16.4.11.2 Alpha and Beta Radiation Surveys

A variety of instruments are available to perform surveys for alpha and/or beta radiation, including gas proportional detectors, plastic scintillators (e.g., phoswich detectors), and Geiger-Mueller (GM) detectors. Due to the short range of alpha radiation, alpha surveys are typically only performed on flat, smooth surfaces. Alpha and beta radiation may be measured in units of cpm and converted to a surface activity concentration of decays per minute per 100 square centimeters (dpm/100cm^2).

16.4.11.3 General Radiation Survey Procedure

The following is a general operating procedure for the use of radiation detection instrumentation for field surveys. Instrument and survey-specific procedures will be included as necessary for site-specific SAPs. Site-specific sampling requirements, such as the required number of measurements and minimum detectable activities, will be determined using MARSSIM and other appropriate guidance.

1. Prior to use, the survey instrument should be calibrated to NIST and other applicable standards by a qualified vendor or manufacturer. The calibration should account for the specific radionuclides of concern at the site, and for any unusual field conditions to be encountered. Calibration of instruments should take place a minimum of once per year.

2. Conduct instrument function checks at a minimum of twice per day – prior to the collection of data, and after the collection of data. Function checks should also be performed if the instrument is damaged, anomalous measurements are suspected, or if batteries are changed. The function checks should include a battery check, a visual inspection for damage, a check of the high voltage setting, a background measurement, and a source measurement with a check source of appropriate type (e.g.,

Cs-137 for gamma radiation, Th-230 for alpha radiation, or Tc-99 for beta radiation). The manufacturer's operating manual for the instrument should be consulted during this process. Background and source function check measurements will be logged and entered into a control chart to monitor the performance of the instrument. If the instrument demonstrates repeatable and unexplainable anomalous function check measurements, it will be removed from service, and data collected with that instrument will be evaluated to determine its usability.

3. Prior to conducting surveys at the impacted area, an appropriate background or reference area should be located. Background surveys should include measurements of the different types of materials expected at the impacted area. An instrument flag value will be developed using the background data and other appropriate action levels.

4. For background and impacted area surveys, proper scanning techniques should be observed. The appropriate scanning procedures are dependant on the radionuclides of concern, the instrument being used, and the desired detection limits. Field scanning techniques for different types of surveys will be included in SOPs for specific site investigations, personnel will be trained in these techniques prior to the start of the field surveys. The SOPs and training will include information on appropriate scanning speed, distance from detector to surface, required use of audio, and other appropriate topics.

5. Collected data will be evaluated on a daily basis by a health physicist or other qualified individual. Errors or concerns will be addressed as soon as possible, while still in the field. After the field survey is complete, the data will be analyzed in accordance with MARSSIM and other applicable guidance.

16.4.12 Filtering Groundwater or Surface Water Samples

Filtered groundwater or surface water samples can only be collected after approval from the project manager. This section provides the procedures for filtering groundwater or surface water samples for dissolved metal analysis. The procedures were modified from the SOP 2200 series developed by Florida DEP (2004).

1. Unless specified by the SS-WP, use a 1 micrometer (µm) filter.

   1.1 Use a disposable, high capacity, 1 µm in-line filter.

      1.1.1 Flush the filter with 30-50 mL of analyte free water or an inert gas (nitrogen) to remove atmospheric oxygen;

   or

1.1.2 Insert the filter on the high pressure side (i.e., on the delivery side) of the pump. Hold the filter upright with the inlet and outlet vertical. Pump water from the aquifer through the filter until all atmospheric oxygen has been removed.

1.2 Use a variable speed pump that can be fitted with an in-line filter on the outlet end. Peristaltic pumps, bladder pumps or submersible pumps can be used when water levels are no greater than 20 to 25 feet deep; bladder pumps or submersible pumps must be used when water levels are greater than 20 to 25 feet deep.

1.2.1 Install new or precleaned silastic tubing in the variable speed peristaltic pump head at each monitoring well.

1.2.2 Use new or precleaned delivery tubing at each monitoring well.

1.3 Collect filtered samples by either of the methods outlined below if the static water level in the well is too deep for a variable speed peristaltic pump and a variable speed electric submersible pump or variable speed bladder pump of appropriate configuration is not available. Do not agitate the sample or expose it to atmospheric oxygen. **Do not** pour the sample into any intermediate vessel for subsequent filtration.

1.3.1 Collect the sample in a Polyethylene, Teflon® or positive pressure bailer that can be pressurized. When the bailer has been retrieved, immediately connect the filter and begin to pressurize the bailer;

or

1.3.2 Collect the sample with a bailer and immediately place the intake tube of the peristaltic pump into the full bailer and begin pumping the water through the filter as described in section 1.2 above.

1.4 Do not use the following equipment for filtering groundwater samples for metals:

1.4.1 Any pump and apparatus combination in which the filter is on the vacuum (suction) side of the pump.

1.4.2 Any type of syringe or barrel filtration apparatus.

1.4.3 Any filter that is not encased in a one-piece, molded unit.

16.4.13 Core Sample Collection

Core samples should be collected following the appropriate SOP to ensure that core samples are representative of the surfaces that they are intended to characterize. This section presents the SOP for concrete core sampling. This SOP was revised from an SOP originally established for PCB analysis. The SOP should be reviewed carefully before being applied for other analysis. Other concrete sampling methods such as the USEPA Region 1 (1997) Draft SOP for Sampling Concrete in the Field (as attached in Appendix F) can be selected for specific project if deemed appropriate.

16.4.13.1 Sampling Preparation

Prior to arriving at the site, the designated Field Team Leader is responsible for completing the following procedures:

1. Obtain proper sampling equipment as listed in Table 25.

2. Obtain a sufficient number of food-grade Ziploc® bags (1-gallon) and appropriate Chain-of-Custody records, custody seals and other supplies. Verify that the analytical laboratory has been contacted and is prepared to receive the samples.

3. Review the SS-WP, the appropriate sampling procedures, the Generic Site-Wide Health and Safety Plan for Seneca Army Depot Activity (Parsons, 2005), and this SAP. Discuss with the Project Manager to establish specific sampling requirements. The SS-WP and SAP and associated appendices must be on-site through task completion for reference by field personnel.

4. Make arrangements with on-site personnel for obtaining site access.

16.4.13.2 Decontamination

Once at the site, the Field Team Leader is responsible for setting up the decontamination area and decontaminating any non-disposable sampling equipment (i.e., coring bits). The coring bits shall be thoroughly cleaned before initial sample collection, between collection of each subsequent sample, and prior to taking the equipment off-site. Decontamination SOP is presented in Section 16.3.11.1.

16.4.13.3 Core Sample Collection

The locations for core sampling shall be clearly marked in the field logbook with the appropriate sample location code. The following steps will be followed to collect core samples from building wall surfaces:

1. Evaluate overhead conditions (e.g., window glass, loose timber, bricks, etc.), and inspect walls for damage, loose debris, or potentially hidden items/conduit prior to coring. Any visual indications of unsafe or unsuitable conditions shall be handled by relocating the core sampling to a different area on the wall.

2. Select the area to be sampled.

3. Install a 2-inch diameter core into the surface using a horizontal portable coring drill. Unless specified by the SS-WP, wall cores will be collected continuously through the full thickness of the wall.

4. Cool the coring bit during coring procedures using distilled water.

5. Collect the cooling water using a wet vacuum and store the water in a 55-gallon DOT-approved drum.

6. Record the location of the surface that was cored, the surface type, and the core thickness in the field log book and on the core sampling record (Appendix C).

7. Place the core(s) into a clean labeled food-grade resealable 1-gallon bag (e.g., Ziploc®).

8. Place the Ziploc® bag with the sample into an empty 1-gallon Ziploc® bag. Place the two Ziploc® bags with the sample into a third 1-gallon Ziploc® bag so the sample is triple bagged and is ready for crushing (to be performed by the laboratory).

9. Place the sample into an ice bath immediately following sample collection until just before sample shipment.

10. Wear disposable powderless nitrile gloves while handling the sample and change gloves and bags between samples.

11. Inspect and document the condition of the sample material including photographic and written records.

12. Pack and ship samples in accordance with the procedures described in Section 16.5.

13. Complete chain-of-custody in accordance with procedures described in Section 16.6.

16.4.13.5 Quality Control Samples

Field quality control samples will include equipment blanks, field replicates (collocated samples), and matrix spike/matrix spike duplicate samples. Equipment or rinsate blanks will be collected by pouring deionized water, provided by the laboratory, over sampling equipment (i.e., coring bit) and collecting the equipment rinse water in appropriate containers with appropriate preservation.

Coded (double-blind) field replicates will be collocated in the field to evaluate core sample collection procedure precisions. Field replicate samples will be collected by taking a second 2-inch core directly adjacent to the original sample.

MS/MSD samples will be collected from sample locations that will yield enough core material for the laboratory to homogenize the entire sample core (i.e., building walls), and remove three aliquots (i.e., the sample, the MS, and the MSD) needed to perform the analysis. Samples to be analyzed as MS/MSDs will be collected following the same procedures outlined above and the sample will be labeled with the sample name and MS/MSD to indicate the sample as a quality control sample.

The quality control samples will be collected at a frequency consistent with Table 13 or the SS-WP.

16.4.13.5 Sample Analysis

Once the cores are received by the laboratory, the core samples will be prepared in accordance with the following procedure unless otherwise specified by the SS-WP. Core samples received by the laboratory will be in triplicate Ziploc® bags. Each triplicate Ziploc® bag with sample will be placed on a hardened concrete floor for crushing. A 4 lb hammer (or suitable equivalent) will be used to break up the core while making a reasonable effort to maintain the integrity of the bags. Rebar located within crushed cores, will be removed by hand when possible. The loose material is transferred to a clean #4 sieve (4.75 mm). Material passing the sieve will be collected in a certified clean wide mouth jar with a Teflon lined closure. The jar will be labeled with the corresponding sample identification and laboratory number. The material retained on the sieve is returned to the corresponding sample bag for further size reduction if more sample mass is required. In some instances the sample bags may require replacement. The process will continue until sufficient sample is obtained to provide for the requested analyses (a minimum of 30 grams for total polychlorinated biphenyls and polychlorinated terphenyls and a minimum of 100 grams for TCLP lead). Unused sample volume will be retained for reanalysis and sample archival.

The 4-pound hammer and #4 sieve will be decontaminated in the laboratory by dusting off both pieces of equipment and then rinsing them with reagent grade water. The equipment will then be scrubbed

with an Alconox and water solution (or equivalent), followed by a second reagent grade water rinse. Lastly, the sampling equipment will be baked in an oven at 110ºC until dry.

16.5 SAMPLE HANDLING

16.5.1 Sample Volumes, Container Types, and Preservation Requirements

Types of sample containers, sample volumes, and methods of preservation are identified in Tables 5A and 5B. The laboratory will supply sample containers and preservatives in accordance with their own analytical procedures. A separate container may not be required for each parameter. The laboratory will add any necessary chemical preservatives prior to shipping the sample containers to the field.

16.5.2 Sample Packaging and Delivery

Samples will be delivered by common carrier to the designated laboratory for analysis daily or every other day, as required. The field team leader (or designee) will contact the laboratory to inform them of sample delivery before samples are to be picked up or delivered to the common carrier. The samples will be delivered in ice chests to the common carrier for overnight delivery. The chain-of-custody forms will be sealed in a plastic bag and taped to the inside lid of the chest. The chest will be sealed with custody seals and tamper-resistant tape, and the custody seals will be signed and dated by the sample custodian.

16.5.3 Sample Identification

Subsurface soil borings will be numbered consecutively beginning with SB-01 (soil borings) or MW-1 (monitoring well borings) or starting with the next consecutive number if existing borings/wells are present.

- Monitoring wells will be numbered consecutively beginning with MW-1.
- Test pits (TP) will be numbered consecutively beginning with TP-1
- Each sample will be given a unique alphanumeric identifier in accordance with the following classification system (such as ALBW-10001, see below):

SAMPLE IDENTIFICATION

LL* or NN*	LL	NNNNN	LL
Site Location	Activity Description /Sample Type	Sample Number	QC Identifier

* LL = Letter or NN = Number

Site Location: AL – Ash Landfill
25 – SEAD-25
26 – SEAD-26

Activity Description/Sample Type:
BW - Biowall
MW - Monitoring Well Boring or Monitoring Well
SB - Soil Boring
SW – Surface Water
TP - Test Pit
SD – Sediment
SS - Surface Soil

Sample Number: Sample type is designated based on a 5-digit numbering system. Sample numbers start with the next consecutive number.
0000# - Trip Blanks
0010# - Field or Rinseate Blanks
1000# - Soil Samples
2000# - Groundwater Samples
3000# - Surface Water Samples
4000# - Sediment/Ditchsoil Samples
5000# - Miscellaneous Samples (such as mulch or debris material).

QC Identifier: MS - Matrix Spike
MSD - Matrix Spike Duplicate

Additional sample identification information or coding maybe found in a SS-WP for a particular site. Field duplicate samples will be assigned identifiers that do not allow the laboratory to distinguish them as field duplicates. Each sample container will be labeled prior to packing for shipment. The sample identifier, site name, date and time of sampling, and analytical parameters will be written on the label in waterproof ink and recorded in the field book.

16.6 SAMPLE CUSTODY

Separate sample custody and documentation procedures will be followed for samples collected for field and laboratory analyses. Components of sample custody are sample labels and chain-of-custody forms. For laboratory analysis, chain-of-custody forms will be completed for each shipment of samples to track the movement of samples and to provide a written record of all persons handling the samples. The chain-of-custody form will include sample information (sample identification, type, date, and time

of collection), analyses requested, and the signature of each person receiving and relinquishing the samples.

The "Remarks" column of the chain-of-custody form will be used to record additional information that may be of use to the laboratory for prescreening the samples. When transferring samples, the individuals relinquishing and receiving the samples will sign, date, and note the time on the chain-of-custody form.

The original chain-of-custody form will accompany the samples to the laboratory. The laboratory will make and maintain a file copy, and the completed original will be returned to the task manager as a part of the final analytical report. This record serves to document sample custody transfer from the sampler to the shipper, and to the laboratory. Upon receipt of samples, the laboratory will provide a written report to the field investigation manager (or designee) summarizing the condition of samples, sample numbers received and corresponding laboratory numbers, and the estimated date for completion of laboratory analysis.

Sample custody within the laboratory may require an internal chain-of-custody. The sample custody documentation shall include the following:

- Name of associate taking custody of the sample from the sample storage area for preparation or analysis;
- Dates sample removed from and returned to the sample storage area;
- Identification of the tests to be performed on the sample aliquot(s) selected by the associate;
- Sample matrix;
- Laboratory sample numbers; and
- Sample storage location.

Access to the laboratory is restricted to prevent any unauthorized contact with samples, extracts, or documentation.

After the requested analyses on the samples have been completed, any remaining portions of the samples shall be stored for the amount of time required by the project and then disposed of by the laboratory. The disposal of each sample shall be recorded in the laboratory's project file or data management system. Disposal of samples shall occur in accordance with the laboratory procedures after the required retention period.

16.7 FIELD QUALITY CONTROL SAMPLES

16.7.1 Equipment Blank/Rinsate Blank

An equipment blank, or a rinsate blank, is a sample of ASTM Type II reagent grade water poured into or over or pumped through the sampling device, collected in a sample container, and transported to the laboratory for analysis. Equipment blanks are used to assess the effectiveness of equipment decontamination procedures. The frequency of collection for equipment blanks will be specified in the SS-WP. Equipment blanks shall be collected immediately after the equipment has been decontaminated. The blank shall be analyzed for all laboratory analyses requested for the environmental samples collected at the site.

16.7.2 Trip Blank

The trip blank consists of a VOC sample vial filled in the laboratory with ASTM Type II reagent grade water, transported to the sampling site, handled like an environmental sample and returned to the laboratory for analysis. Trip blanks are not opened in the field. Trip blanks are prepared only when VOC samples are taken and are analyzed only for VOC analytes. Trip blanks are used to assess the potential introduction of contaminants from sample containers or during the transportation and storage procedures. One trip blank shall accompany each cooler of samples sent to the laboratory for analysis of VOCs. In accordance with the USEPA Region 2 (1989) CERCLA Quality Assurance Manual, an aqueous trip blank is not required when non-aqueous samples are collected.

16.7.3 Field Duplicates

A field duplicate sample is a second sample collected at the same location as the original sample. Duplicate samples are collected simultaneously or in immediate succession, using identical recovery techniques, and treated in an identical manner during storage, transportation, and analysis. The sample containers are assigned an identification number in the field such that they cannot be identified (blind duplicate) as duplicate samples by laboratory personnel performing the analysis. Specific locations are designated for collection of field duplicate samples prior to the beginning of sample collection.

Duplicate sample results are used to assess precision of the sample collection process. Precision of soil samples to be analyzed for VOCs is assessed from collocated samples because the compositing process required to obtain uniform samples could result in loss of the compounds of interest. It is recommended to collect one sample per week or 10% of all field samples per matrix, whichever is greater (USEPA, 2004b).

16.7.4 Field Replicates

A field replicate sample, also called a split, is a single sample divided into two equal parts for analysis. The sample containers are assigned an identification number in the field such that they cannot be identified as replicate samples by laboratory personnel performing the analysis. Specific locations are designated for collection of field replicate samples prior to the beginning of sample collection. Replicate sample results are used to assess precision. The frequency of collection for field replicates is specified in Table 7-A through 7-G.

16.7.5 Matrix Spike and Matrix Spike Duplicate

Matrix spike and matrix spike duplicate samples will be collected from areas that are known or suspected to be contaminated. Additional volume will be required for aqueous samples and soil VOA samples designed for MS/MSD analyses. The extra volume containers will be marked as the sample number and the "MS/MSD".

16.8 FIELD MEASUREMENTS

16.8.1 Parameters

The following is a list of all parameters that may be measured during field activities, as well as the equipment that will be used for the measurements:

Parameter	**Equipment**
Volatiles	MiniRae 2000 (or equivalent)
Water turbidity	Lamotte 2020 Turbidity Meter (or similar)
Water dissolved oxygen	Horiba U22 (or equivalent)
Temperature	Horiba U22 (or equivalent)
Specific Conductivity	Horiba U22 (or equivalent)
Oxygen Reduction Potential (ORP)	Horiba U22 (or equivalent)
pH	Horiba U22 (or equivalent)
Sulfate/sulfide	Hach® DR/850 Portable Colorimeter (or similar)
Nitrite	Hach® DR/850 Portable Colorimeter (or similar)
Alkalinity	Hach® DR/850 Portable Colorimeter (or similar)
Dissolved CO_2	Hach® Digital Titrator (or similar)
Nitrogen, Ammonia	Hach® Spectrophotometer (or similar)
Manganese	Hach® DR/4000 1-Inch Cell Adapter (or similar)

Ferrous iron	Hach® AccuVac Ampuls (or similar)
Air particulates	Personal Aerosol Monitor

The instruction manuals for the Lamotte 202 Turbidity Meter, the MiniRae 2000, the Horiba U-22, and the Hach® instruments are presented in Appendix G. Any additional equipment needed for a specific project or task shall be identified in the SS-WP.

16.8.2 Equipment Calibration and Quality Control

As required, field analytical equipment shall be calibrated according to the manufacturers' specifications prior to field use. This applies to equipment used for onsite measurements of DO, pH, specific conductance, ORP, and other field parameters. Initial and daily calibrations will be recorded in the field notebook. In addition the reference electrode utilized for ORP and the appropriate conversion factor will be recorded in the field notebook.

16.8.3 Field Monitoring Measurements

16.8.3.1 Groundwater Level Measurements

Water-level measurements shall be taken in all wells and piezometers to determine the elevation of the water table or piezometric surface at least once within a single 24-hour period. These measurements shall be taken after all wells and piezometers have been installed and developed and their water levels have recovered completely. Any conditions (e.g., barometric pressure) that may affect water levels shall be recorded in the field log. The field log shall also include the previous water level measurement for each well (to determine if current water level is reasonable).

Water-level measurements shall be taken with electric sounders, air lines, pressure transducers, or water-level recorders (e.g., Stevens recorder). Devices that may alter sample composition shall not be used. Pressure gauges, manometers, or equivalent devices shall be used for flowing wells to measure the elevation of the piezometric surface. All measuring equipment shall be decontaminated according to the specifications in Section 16.3.11. Ground-water level shall be measured to the nearest 0.01 foot. (Two or more sequential measurements shall be taken at each location until two measurements agree to within + or - 0.01 foot.)

Static water levels shall be measured each time a well is sampled, and before any equipment enters the well. If the casing cap is airtight, allow time prior to measurement for equilibration of pressures after the cap is removed. Repeat measurements until water level is stabilized.

16.8.3.2 Floating Hydrocarbon Measurements

The thickness of hydrocarbons floating in monitor wells shall be measured with an electronic interface probe. Hydrocarbon detection paste, or any other method that may affect water chemistry, shall not be used. When detected, the presence of floating hydrocarbons shall be confirmed by withdrawing a sample with a clear, bottom-fill Teflon® bailer.

16.8.3.3 Groundwater Discharge Measurements

Groundwater discharge measurements shall be obtained during monitor well purging and aquifer testing. Groundwater discharges may be measured with orifice meters, containers of known volume, in-line meters, flumes, or Weirs, following the guidelines specified in the Water Measurement Manual (USDoI, 2001). Measurement devices shall be calibrated using containers of known volume.

16.8.3.4 Sulfate/Sulfide Measurements

Sulfide concentrations in groundwater cannot be measured using a probe and will be analyzed in the field via colorimetric analysis with a Hach® DR/850 Portable Colorimeter (or similar) after appropriate sample preparation. USEPA-approved Hach® Method 8131 (0 to 0.70 mg/L) will be used to analyze for sulfide. The manual for the colorimeter, including calibration procedures, and the procedures for Method 8131 are contained in Appendix G.

16.8.3.5 Nitrite Measurements

Nitrite concentrations in groundwater cannot be measured using a probe, so a Hach® DR/850 Portable Colorimeter (or similar) and Hach® Method 8507 (0 to 0.350 mg/L) will be utilized in the field to determine these concentrations. The manual for the colorimeter, including calibration procedures, and the procedures for Method 8507 are contained in Appendix G.

16.8.3.6 Alkalinity Measurements

Alkalinity of the groundwater sample will be measured in the field by via titrimetric analysis using USEPA-approved Hach® Method 8221 (0 to 5,000 mg/L as calcium carbonate), or equivalent. The procedures for this method are contained in Appendix G.

16.8.3.7 Portable Photoionization Analyzer

The photoionization analyzer will be a RaeSystems MiniRae 2000 (or equivalent), equipped with a 10.6 eV lamp. The MiniRae is capable of ionizing and detecting compounds with an ionization potential of

less than 10.6 eV. This accounts for up to 73% of the volatile organic compounds on the Target Compound List.

Calibration must be performed at the beginning and end of each day of use with a standard calibration gas having an approximate concentration of 100 parts per million of isobutylene. If the unit experiences abnormal perturbation or erratic readings, additional calibration will be required.

All calibration data must be recorded in field notebooks and on calibration log sheets to be maintained on-site.

A battery check must be completed at the beginning and end of each working day.

16.8.3.8 Personal Aerosol Monitor

The operator shall ensure that the instruments respond properly to the substances that they are designed to monitor. Real time aerosol monitors must be zeroed at the beginning of each sampling period. The specific instructions for calibration and maintenance provided for each instrument should be followed. All calibration data must be recorded in field notebooks and on calibration log sheets to be maintained on-site.

A battery check must be completed at the beginning and end of each working day.

16.8.3.9 pH Meter

Calibration of the pH meter must be performed at the start of each day of use, and after very high or low readings as required by this plan, according to manufacturer's instructions.

National Institute of Standards and Technology - traceable standard buffer solutions which bracket the expected pH range will be used. The standards will be pH of 4.0, 7.0 and 10.0 standard units.

The use of the pH calibration must be used to set the meter to display the value of the standard being checked. The calibration data must be recorded on calibration sheets maintained on-site or with the piece of equipment.

16.8.3.10 Specific Conductivity Meter and Temperature Probe

Calibration checks using the conductivity standard must be performed at the start of each day of use, after five to ten readings or after very high or low readings as required by this plan, according to manufacturer’s instructions.

The portable conductivity meter must be calibrated using a reference solution of 200 uohms/cm on a daily basis. Readings must be within five percent to be acceptable. The thermometer of the meter must be calibrated against the field thermometer on a weekly basis.

16.8.3.11 Turbidity, Dissolved Oxygen, Dissolved CO_2, Ferrous Iron, Manganese, Sulfide, Ammonia, and Oxygen Reduction Potential Meters

These meters must be checked at the start of each day of use and at the end of the day.

16.8.4 Field Performance and System Audits

Field activities will be monitored on a per-task basis by the Technical Director or his/her designee to ensure compliance with this SAP and the SS-WP. Field performance and system audits will be conducted in accordance with the specifications presented in Section 9.1.2 and Section 9.2.2.

16.8.5 Field Environmental Data Reporting: Significant Digits Reflect Quantification Uncertainty

Field measurements of common water-quality parameters, other screening analytical data, calculations of aquifer properties (e.g., hydraulic conductivity, transmissivity, groundwater velocity), and quantities of contaminated soil and water removed and/or treated possess measurable uncertainty or error ranges. When reporting these data, therefore, the number of significant figures employed should reflect the true accuracy and precision (reproducibility) of these measured and calculated values. As a general rule of thumb, field measurements of water quality parameters, quantities of contaminated media removed/remediated, screening analytical data and calculated aquifer properties rarely yield better than two-significant-figure accuracy and precision. Consequently, these field-measured parameters typically should be reported to two significant figures (e.g., DO, 2.1 mg/L; hydraulic conductivity, 120 ft/day; transmissivity, 1,100 ft^2/day; 130 tons of contaminated soil excavated) unless notably low uncertainty exists to justify reporting to three or more significant figures. Manufacturer's performance specifications that document high accuracy and precision for field meters may constitute an example of valid justification for reporting field values to three or more significant figures. Because pH and oxidation-reduction potential are logarithmic values, recommend reporting these parameters to three significant figures. In all cases, standard reporting practice should involve consistency in the number of significant figures used to report measured values.

Use of scientifically defensible and consistent numbers of significant figures in reporting analytical and quantitative field data allows the readers and users of these data to properly evaluate measurement uncertainty. This proper evaluation of data accuracy and precision facilitates the scientifically valid

interpretation, summarization and subsequent reporting of these data. Field team members are encouraged to comply with *Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications* (ASTM Designation: E 29-02, 2002).

16.9 RECORD KEEPING

Bound field logbooks will be maintained by the field supervisor and other team members to provide a daily record of significant events, observations, and measurements during the field investigation. All entries will be signed and dated. All information pertinent to the field survey and/or sampling will be recorded in the logbooks. The logbooks will be bound, with sequentially numbered pages. Waterproof ink will be used in making all entries. Entries in the logbook will include, at a minimum, the items listed below:

General information:

- Names and titles of author and assistants;
- Date and time of entry;
- Physical/environmental conditions during field activity;
- Purpose of sampling activity;
- Location of sampling activity; and
- Names and titles of field crew.

Sampling documentation:

- Sample medium (e.g., groundwater, soil);
- Description of sampling point(s);
- Date and time of collection;
- Sample identification; and
- Sample analyses and containers.

Other information:

- Names and titles of site visitors;
- Field observations (i.e., unusual field conditions);
- Field measurements (such as pH, conductivity, temperature) and specific instrument calibration data;
- Field equipment (make, model, serial number);
- Equipment decontamination frequency; and
- Sample handling (e.g., preservation with ice) and shipping (i.e., shipping company, air bill number) information.

None of the field logbooks or forms will be destroyed or discarded, even if they are illegible or contain inaccuracies that require a replacement document. If a previously recorded entry is discovered to be incorrect, the incorrect entry will be crossed out in such a manner that it is still legible. The correct entry will be written in, and the change will be initialed and dated. If the change is made by someone other than the original author, or if the change is made on a subsequent day, a reason for the change will be recorded at the current active location in the logbook, with cross references.

Field personnel shall maintain field records sufficient to recreate all sampling and measurement activities. The requirements listed in this section apply to all measuring and sampling activities. Requirements specific to individual activities are listed in the section that addresses each activity. The information shall be recorded with indelible ink in a permanently bound notebook with sequentially numbered pages. These records shall be archived in an easily accessible form and made available to the Air Force upon request.

17.0 REQUIREMENTS FOR SITE-SPECIFIC WORK PLAN

This generic site-wide SAP will serve as an umbrella document under which project-specific tasks are conducted. This SAP will provide the majority of the QA/QC information and field sampling SOPs; the SS-WP should simply supplement this information by providing site-specific requirements. This section summarizes the key elements of SAP that should be covered in the SS-WP.

The following presents a list of the key elements of DQOs that should be included in the SS-WP, in accordance with the USEPA, NYSDEC, and USACE guidance documents.

1. Project/task description, which include a summary of all work to be performed, products to be produced, the schedule for implementation, the project's scope and project goals as well as how the project relates to the overall site investigation or remediation strategy;

2. Data use background, which should include sufficient background information to provide a historical, scientific, and regulatory perspective, project-specific data needs that have been identified (i.e., specific problem to be solved or outcome to be achieved), short-term decisions that will be made during the project planning phase, and long-term decisions that will be made prior to project closeout, a brief summary of the type of samples (media) and analyses (screening versus definitive, and applicable chemical parameters) that will be required to meet the data needs.

3. Project organization, including the designation of a project manager, quality assurance officer, and field analyst, (if field analysis is planned);

4. Site map showing sample locations;

5. An "Analytical Methods/Quality Assurance Summary Table" which should include the following information for all environmental, performance evaluation, and quality control samples:

    - matrix type;
    - number or frequency of samples to be collected per matrix;
    - number of field and trip blanks per matrix;
    - analytical parameters to be used per matrix;
    - analytical methods to be use per matrix;
    - the number and type of matrix spike and matrix spike duplicate samples to be collected;
    - the number and type of duplicate samples to be collected;
    - the number and type of split samples to be collected, if warranted;
    - the number and type of performance evaluation samples to be analyzed, if warranted;
    - sample preservation to be used per analytical method and sample matrix;

- sample container volume and type to be used per analytical method and sample matrix; and
- sample holding time to be used per analytical method and sample matrix.

6. A summary of QC activities needed for each sampling, analysis, or measurement technique.

7. Definition and requirement of data completeness for the project.

8. Information of the laboratory that will perform chemical analysis (laboratory name, address, contact information and current certifications for the analyses performed). A laboratory QA/QC manual should be included or cross-referenced to in accordance with the NYSDEC (2001) Development and Review of Site Analytical Plans.

9. Site-specific DQOs, which includes outputs from the systematic planning process used to design the study and measurement performance or acceptance criteria established as part of the study design. Information of this key element can be found in USEPA (2000a) QA/G-4, USEPA QA/G-5 Section 2.1.7, and USEPA (2005a) Uniform Federal Policy for Quality Assurance Project Plans Section 2.6.

10. Sampling process design (e.g., assumptions made, scale of representativeness, type of sampling design – probability-based or judgmental, sampling sites location method). Information of this key element can be found in USEPA (2002a) QA/G-5 Section 2.2.1 and USEPA (2005a) Uniform Federal Policy for Quality Assurance Project Plans Section 3.1.1.

11. Specialized training or certification, if needed and plans for providing, documenting, and assuring this training.

12. Existing data that will be obtained from non-measurement sources, intended use of non-direct measurements, and acceptance criteria and any limitations for using such data. Information of this key element can be found in USEPA (2002a) QA/G-5 Section 2.2.9.

13. Reconciliation with user requirements. Information of this key element can be found in USEPA (2002a) QA/G-5 Section 2.4.3.

14. Any QA/QC and field sampling protocols that are different from or not covered in this SAP (e.g., sampling procedures and methods, sample storage and handling, sample delivery, and equipment decontamination procedures).

15. Criteria for comparability between screening data and definitive data, when definitive analysis is performed to confirm screening results.

16. Requirement for laboratory reporting limits or method detection limits.

17. SS-WP distribution list and sign-off sheet.

18. Decontamination area designated for specific sampling events and any modification of decontamination methods.

19. Waste disposal companies and disposal facilities, if warranted.

20. Instruction, operational manual, and operational requirements for any equipments that will be used for the site and are not covered in this SAP.

21. QA/QC requirements for any screening and definitive analytical methods not covered in this SAP. And

22. Any variances from this SAP such as: 1) if field audits are warranted, SOPs for field audit will be specified in the SS-WP; 2) sediment sampling depth should be specified if samples are not to be collected with 6 inches; etc.

23. Specification of instrument makes and models, instrument manuals, and survey-specific procedures for radiological surveys.

* Potential ARAR/TBC values are from NYSDEC Technical and Administrative Guidance Memorandum (TAGM) #4046

(on-line resources available at http://www.dec.state.ny.us/website/der/tagms/prtg4046.html)
** Potential ARAR/TBC values for NYSDEC Technical Guidance for Screening Contaminated Sediment. All values except for inorganic values were calculated based on a Total Organic Carbon of 39,105 mg/Kg (SEDA site average).

(1) Carcinogenic DNT mixture values used if more conservative than noncarcinogenic isomer-specific values
(2) Total chromium values used if available. All Region 3 values are based on hexavalent chromium.
(3) Lower of the industrial values provided (industrial w/o dermal vs. industrial/outdoor)
(4) Noncancer RBCs at an HI of 0.1 provided because screening at an HI of 0.1, in accordance with Region 3 guidance, will result in noncancer RBCs being lower than the cancer RBCs
(5) Perchlorate Region 9 PRG value is based on perchlorate acid.

Region 9 PRGs, dated January, 2005
Region 3 RBCs, dated April 2005
Region 6 SSLs, dated 21 December 2004

* New York State Ambient Water Quality Standards, GA (http://www.dec.state.ny.us/website/regs/part701.html)
** Guidance value in NYSDEC AWQS, Class GA groundwater or Class C surface water.

(1) Carcinogenic DNT mixture values used if more conservative than noncarcinogenic isomer-specific values
(2) Total chromium values used if available. All Region 3 values are based on hexavalent chromium.
(3) Lower of the industrial values provided (industrial w/o dermal vs. industrial/outdoor)
(4) Noncancer RBCs at an HI of 0.1 provided because screening at an HI of 0.1, in accordance with Region 3 guidance, will result in noncancer RBCs being lower than the cancer RBCs
(5) All MCLs are primary except those with this footnote.
(6) All HAs are lifetime except those footnoted, which are based on 10-4 cancer risk
(7) Drinking Water Equivalent Level
(8) Drinking Water Advisory
(9) Non-Priority pollutant
(10) Perchlorate Region 9 PRG value is based on perchlorate acid.
(11) Xlyene Class C surface water value used 1,4-Xlyene (106-42-3).
(12) 4,4-DDD, -DDE, -DDT Class C surface water values based on the sum of DDD, DDE, and DDT equal to 1.1E-5 ug/L.
(13) Inorganic Class C surface water values are based on an assumed hardness of 217 mg/L.

Table 2
Project Communication Pathways

Communication Drivers	Responsible party	Name	Phone Number	Procedure
Approval of QAPP/amendments to QAPP	USEPA PM NYSDEC PM SEDA PM	Julio F. Vazquez Kuldeep K. Gupta Steve Absolom	212-637-4323 518-402-9620 607-869-1309	Parsons PM will initiate calls to SEDA if review time passed the scheduled review period. SEDA will then call USEPA and NYSDCE PM to discuss QAPP/amendment schedule.
Notification of delays or changes to field work	Parsons PM	Todd Heino	617-449-1405	Parsons field team leader will update PM daily filed progress. Parsons PM will update SEDA any delay or change of field activities.
Recommendations to stop work and initiation of corrective action	Parsons PM Parsons Health and Safety Officer	Todd Heino	617-449-1405	Parsons PM or Health and Safety Officer will initiate a work stoppage due to QA/QC concerns, health and safety concerns, or any other project related concerns.
Reporting of issues related to analytical data quality	Parsons Chemist	Chunhua Liu	617-449-1567	Parsons chemist will initiate discussion with the Laboratory with any data quality issues.
Quality Assurance and Changes to the QAPP	PARSONS Quality Assurance Officer	James Lowerre	617-449-1559	Parsons QA Officer will not be involved in the data generation process. However, the QA Officer will initiate internal discussion with PM and project team regarding any QA issues and corrective actions.

Table 3
Summary of Screening Analytical Methods and Method Quantitation Limits

Reference Number	Title, Revision Date, and/or Number	Analytical Group	Instrument	Organization Performing Analysis	Modified for Project? (Y/N)	Method Quantitation Limits [1]
USEPA Method 160.1/160.3/ASTM D2216-90/D2216-05	Residue, Total (Gravimetric, Dried at 103-105°C), Approved for NPDES (Issued 1971) Standard method for laboratory determination of water (moisture) content of soil and rock	Percent Solids	Drying Oven	Laboratory	No	0.1%
SW846 Method 1010A/ 1020B/ 1030	Pensky-Martens Closed-Cup Method For Determining Ignitability, Revision 1, 2002; Small Scale Closed-Cup Method For Determining Ignitability, Revision 2, 2002; Ignitability of Solids, Revision 0, 1996	Ignitability	Pensky-Martens Closed-Cup Tester; Small Scale Closed-Cup Apparatus; A Bunsen burner	Laboratory	No	1ºF
SW846 Method 1110	Corrosivity Toward Steel, Revision 0, 1996	Corrosivity	A resin flask	Laboratory	No	
SW846 Method 9040C	Electrometric Measurement, Revision 3, 2002	pH (water)	pH meter	Laboratory/Field	No	
SW846 Method 9045D	Soil and Waste pH, Revision 4, 2002	pH (soil)	pH meter	Laboratory/Field	No	
SW846 Method 9050A	Specific Conductance, Revision 1, 1996	conductance	Self-contained conductivity instruments	Laboratory/Field	No	
USEPA Method 130.1	Hardness, Total (mg/L as $CaCO_3$) (Colorimetric, Automated EDTA) - Approved for NPDES (Issued 1971)	Hardness	Spectrophotometer	Laboratory/Field	No	10 mg/L
USEPA Method 170.1	Temperature - Approved for NPDES (Issued 1974)	Temperature	Thermometer	Laboratory/Field	No	
USEPA Method 180.1	Determination Of Turbidity By Nephelometry, Revision 2, 1993.	Turbidity	Nephelometry	Laboratory/Field	No	
E310.1/Hach Method 8203/8221 or similar	Alkalinity (Titrimetric, pH 4.5) - Approved for NPDES (Editorial Revision 1978)	Alkalinity	PH meter or electrically operated titrator	Laboratory/Field	No	10 mg/L

Table 3
Summary of Screening Analytical Methods and Method Quantitation Limits

Reference Number	Title, Revision Date, and/or Number	Analytical Group	Instrument	Organization Performing Analysis	Modified for Project? (Y/N)	Method Quantitation Limits [1]
E360.1 with commercially available probe	Oxygen, Dissolved (Membrane Electrode) - Approved for NPDES (Issued 1971)	Dissolved oxygen	Oxygen Analyzer	Laboratory/Field	No	
Organic Vapor Analysis	SOP (Section 16 of this SAP)	Hydrocarbon vapor	Photoionization Detector (PID)	Field	No	0.05~0.5 ug/L or ug/kg
USEPA Method 353.1/353.2/Hach 8507	Nitrogen, Nitrate-Nitrite (Colorimetric, Automated, Hydrazine Reduction) - Approved for NPDES and SDWA (Reissued w/Rev. 1978)	Nitrate, nitrite	Spectrophotometer	Laboratory/Field	No	0.01 mg/L
ASTM D1498 with commercially available ORP	Standard Practice for Oxidation-Reduction Potential of Water	Oxidation-reduction potential	ORP instrument	Field	No	
Hach 8146	Iron, Ferrous Method 8146 DR/2500.	Ferrous iron	Hach system	Field	No	0.02 mg/L
Hach 8034	Manganese Method 8034 WAH, DR/4000, DR/2500, DR/2400, or Genesys	Manganese	Hach system	Field	No	0.2 mg/L
Hach 8131	Sulfide Method 8131 WAH, DR/4000, DR/2500, DR/2400, or Genesys	Sulfide	Hach system	Field	No	5 mg/L
Hach 8205	Carbon Dioxide Method 8205 WAH	CO_2	Hach system	Field	No	10 mg/L
USEPA Method 160.1	Residue, Filterable (Gravimetric, Dried at 180°C) - Approved for NPDES (Issued 1971)	TDS	Drying oven	Laboratory	No	10 mg/L
USEPA Method 160.2	Residue, Non-Filterable (Gravimetric, Dried at 103-105°C) - Approved for NPDES (Issued 1971)	TSS	Drying Oven	Laboratory	No	4 mg/L
USEPA Method 350.3/HACH 8038/8155	Nitrogen, Ammonia (Potentiometric, Ion Selective Electrode) - Approved for NPDES (Issued 1974)	Ammonia	Ion selective electrode/	Laboratory/Field	No	0.03 mg/L
SW846 Section 7.3	Reactivity	Reactivity	Depending on sample characteristic	Laboratory	No	Depending on sample characteristic

Note: 1. Method quantitation limit listed by the method. Method reporting limit provided by the laboratory will be reviewed for each specific project.

Table 4
SUMMARY OF DEFINITIVE ANALYTICAL METHODS

Reference Number	Title, Revision Date, and/or Number	Analytical Group	Instrument
CLP OLC03.2/ASP2000	CLP Statement of Work (SOW) for Low Concentration Organic Analysis, OLC03.2 and NYSDEC (2000) ASP	Aqueous low concentration for VOCs, SVOCs, pesticides, and PCBs.	GC/MS (VOCs/SVOCs), GC/ECD (pesticides/PCBs)
CLP OLM04.3/ASP2000	CLP Statement of Work for Multi-Media, Multi-Concentration Organics Analysis, OLM04.3 and NYSDEC (2000) ASP.	VOCs, SVOCs, pesticides, PCBs	GC/MS (VOCs/SVOCs), GC/ECD (pesticides/PCBs)
SW846 Method 8260B	Volatile Organic Compounds By Gas Chromatography/Mass Spectrometry (GC/MS), Revision 2, 1996	Volatile organic compounds	GC/MS
SW846 Method 8270C	Semivolatile Organic Compounds By Gas Chromatography/Mass Spectrometry (GC/MS), Revision 4, 1998	Semivolatile Organic Compounds	GC/MS
SW846 Method 8081A/B	Organochlorine Pesticides By Gas Chromatography	Pesticides	GC
SW846 Method 8082A	Polychlorinated Biphenyls (PCBs) By Gas Chromatography	PCBs	GC
SW846 Method 6010B	Inductively Coupled Plasma-Atomic Emission Spectrometry, Revision 2, 1996	Metals	ICP/AES
SW846 Method 7471A	Mercury In Solid Or Semisolid Waste (Manual Cold-Vapor Technique), Revision 1, 1994	Mercury	Atomic absorption spectrophotometer
SW846 Method 9012A	Total And Amenable Cyanide (Automated Colorimeteric,With Off-line Distillation), Revision 1, 1996	Cyanide	Colorimeter
SW846 Method 8330	Nitroaromatics And Nitramines By High Performance Liquid Chromatography (HPLC), Revision 0, 1994	Nitroaromatics And Nitramines	HPLC
CLP ILM06.X/ASP2000	CLP Statement of Work for Multi-Media, Multi-Concentration Inorganic Analysis, ILM06.X and NYSDEC (2000) ASP	Metals and cyanide	ICP/AES or ICP/MS, AA (mercury), Spectrophotometer (cyanide)
SW846 Method 7580A	White Phosphorus (P) By Solvent Extraction And Gas Chromatography, Revision 0, 1990	White Phosphorus	Gas chromatograph
USEPA Method 314.0	Determination Of Perchlorate In Drinking Water Using Ion Chromatography, Revision 1.0, 1999	Perchlorate	Ion Chromatograph
SW846 Method 7196A	Chromium, Hexavalent (Colorimetric), Revision 1, 1992	Hexavalent chromium	Spectrophotometer or filter photometer
USEPA Method 335.2	Cyanide, Total (Titrimetric; Spectrophotometric) - Approved for NPDES (Technical Revision 1980)	Total cyanide	Spectrophotometer
USEPA Method 365.1/365.2	Phosphorous, All Forms (Colorimetric, Ascorbic Acid, Single Reagent) Approved for NPDES (1971)	Total phosphorus	Spectrophotometer
Method 418.1	Petroleum Hydrocarbons (Infrared Spectrophotometric)	Total Petroleum Hydrocarbons	Spectrophotometric, Infrared
USEPA 351.2 / SM4500	Determination of Total Kjeldahl Nitrogen by Semi-Automated Colorimetry	Total Kjeldahl Nitrogen (TKN)	Colorimeter

Table 4
SUMMARY OF DEFINITIVE ANALYTICAL METHODS

Reference Number	Title, Revision Date, and/or Number	Analytical Group	Instrument
RSK-175, USEPA Method 8015D, or AM20GAX	Analysis of Dissolved Methane, Ethane, and Ethylene in Groundwater by a Standard Gas Chromatograph Technique; Nonhalogenated Organics Using GC/FID, Revision4, 2003; Analytical Method AM20GAX Standard Operating Procedure for the Analysis of Biodegration Indicator Gases	Methane, Ethane, Ethene	Gas chromatograph/flame ionization detector GC/FID/TCD/RGD
SW846 Method 9060A/USEPA Method 415.1/Lloyd Kahn	Total Organic Carbon, Revision 1, 2002 Organic Carbon, Total (Combustion Or Oxidation) - Approved for NPDES (Editorial Revision 1974) Determination of Total Organic Carbon in Sediment, Lloyd Kahn, 1988	Total Organic Carbon	carbonaceous analyzer
USEPA Method 410.1	Chemical Oxygen Demand (Titrimetric, Mid-Level) - Approved for NPDES (Editorial Revision 1978)	Chemical Oxygen Demand	
USEPA Method 300.1 / USEPA Method 300.2 / SW846 Method 9056	Determination Of Inorganic Anions In Drinking Water By Ion Chromatography, Revision 1, 1999. Determination Of Inorganic Anions By Ion Chromatography, Revision 0, 1994	Nitrate, nitrite, chloride, sulfate	Ion Chromatography
UEPA Method 405.1	Biochemical Oxygen Demand (5 Days, 20°C) - Approved for NPDES (Editorial Revision 1974)	BOD	Oxygen probe
SW846 Method 1311 followed by 8260B	Toxicity Characteristic Leaching Procedure; Volatile Organic Compounds By Gas Chromatography/ Mass Spectrometry (GC/MS)	TCLP VOCs	GC/MS
SW846 Method 1311 followed by 8270C	Toxicity Characteristic Leaching Procedure; Semivolatile Organic Compounds By Gas Chromatography/Mass Spectrometry (GC/MS)	TCLP SVOCs	GC/MS
SW846 Method 1311 followed by 8081B	Toxicity Characteristic Leaching Procedure; Organochlorine Pesticides By Gas Chromatography	TCLP pesticides	GC
SW846 Method 1311 followed by 8082A	Toxicity Characteristic Leaching Procedure; Polychlorinated Biphenyls (PCBs) By Gas Chromatography	TCLP PCBs	GC
SW846 Method 1311 followed by 8151A	Toxicity Characteristic Leaching Procedure; Chlorinated Herbicides By GC Using Methylation Or Pentafluorobenzylation Derivatization	TCLP herbicides	GC
SW846 Method 1311 followed by 6010B or 6020A	Toxicity Characteristic Leaching Procedure; Inductively Coupled Plasma –Atomic Emission Spectrometry; or Inductively Coupled Plasma – Mass Spectrometry	TCLP metals	AES or MS
40CFR261.23	Characteristic of Reactivity	Reactivity	
SW846 Method 1010A, ASTM D93-79, D93-80, or D3278-78	Pensky-Martens Closed-Cup Method For Determining Ignitability	Flashpoint	Pensky-Martens closed-cup tester
SW846 Method 9040C	pH Electrometric Measurement	pH	pH meter

Notes:

1) The above reference methods are from the following literatures:
   a) Test Methods for Evaluating Solid Waste, Physical/Chemical Methods (USEPA SW-846, Third Edition) and its subsequent updates.
   b) Methods for Chemical Analysis of Water and Waste (USEPA, 1979).
2) All definitive analyses will be conducted by selected laboratory. The laboratory should conduct the analyses in accordance with all NYSDEC ASP requirements and requirements specified in this ASP.

Table 5-A

Sample Containers, Preservatives, and Holding Times for Soils and Sediments

Parameter	Sample Container	Preservative	Technical Holding Time [1]	Laboratory Holding Time [2]
Metals	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	28 days (Hg); 24 hours (hex chromium); 14 days (cyanide); 180 days (others)	26 days (Hg); 24 hours (hex chromium)[d]; 12 days (cyanide), 178 days (others)
Explosives	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
Perchlorate	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	28 days	26 days
SVOCs	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
Pesticides/PCBs	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
VOCs (low level)	3 Encore samplers	Ice, Cool to 4°C	14 days	Preserve within 24 hours and analyze within 12 days
VOCs (medium or high level)	1 4 oz wide-mouth glass w/ Teflon-lined cap	Methanol, Ice, Cool to 4°C or preserve at the laboratory	10 days	8 days
TOC	1 4 oz wide-mouth glass w/ Teflon-lined cap	Ice, Cool to 4°C	14 days	12 days
Total Kjeldahl Nitrogen (TKN)	1 500 mL plastic or glass bottle	Ice, Cool to 4°C	28 days	26 days
Total Cyanide	1 500 mL plastic or glass bottle	Ice, Cool to 4°C	14 days	12 days
Iorn, Phosphorus, Potassium	1 4oz glass jar	Ice, Cool to 4°C	Iron and potassium - 180 days Phosphorus – 28 days	Iron and potassium - 178 days Phosphorus – 26 days
TCLP VOC	1 8 oz wide mouth glass with Teflon-lined cap	Ice, Cool to 4°C	14/NA/14[b]	7/NA/7[b]
TCLP SVOC	1 8 oz wide mouth glass with Teflon-lined cap	Ice, Cool to 4°C	14/7/40 [b]	5/7/40 [b]
TCLP Mercury	1 8 oz wide mouth glass with Teflon-lined cap	Ice, Cool to 4°C	28/NA/28 (mercury) [b]	5/NA/28 (mercury) [b]

Table 5-A

Sample Containers, Preservatives, and Holding Times for Soils and Sediments

Parameter	Sample Container	Preservative	Technical Holding Time [1]	Laboratory Holding Time [2]
TCLP Metals (except Mercury)	1 8 oz wide mouth glass with Teflon-lined cap	Ice, Cool to 4°C	180/NA/180 [b]	178/NA/180 [b]
Reactivity	2 4-oz plastic jar	Ice, Cool to 4°C	7	5
Flashpoint	1 100 ml plastic or glass bottle	Ice, Cool to 4°C	7	5
pH	1 4-oz plastic jar	Ice, Cool to 4°C	ASAP	ASAP

Notes:

1. Technical holding time between sample collection and sample analysis. Based on Region 2 SOPs, NYSDEC (2000) ASP, and method requirements.

2. Laboratory holding time requirement to meet technical holding time requirement. Holding time from Verified Time of Sample Receipt (VTSR) at the laboratory. Based on NYSDEC (2000) ASP and technical holding time requirement.

[a] number of days between sample collection and extraction / number of days between extraction and analysis;

[b] number of days between sample collection and TCLP extraction/number of days between TCLP extraction and preparative extraction/number of days between preparative extraction and analysis.

[c] TCLP SVOCs includes all semivolatiles, pesticides, and herbicides.

[d] Meet the laboratory holding time requirement does not automatically meet the technical holding time requirement. Special arrangement needed to meet the technical holding time requirement.

Table 5-B

Sample Containers, Preservatives, and Holding Times for Aqueous Samples

Parameter	Sample Container	Preservative	Technical Holding Time [1]	Laboratory Holding Time [2]
Metals	1 500-ml plastic bottle	pH<2, with HNO3, Ice, Cool to 4ºC	28 days (Hg); 24 hours (hex chromium); 180 days	26 days (Hg); 24 hours (hex chromium)[d]; 178 days
Explosives	2 1-L amber bottles	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
Inorganic Ions	1 500-ml plastic bottle	Ice, Cool to 4°C	Nitrate, Nitrite - 48 hours Chloride, fluoride, sulfate – 28 days	Nitrate, Nitrite – 24 hours Chloride, fluoride, sulfate – 26 days
Perchlorate	1 250-ml plastic or glass bottle	Ice, Cool to 4°C	28 days	26 days
Alkalinity	1 250-ml plastic or glass bottle	Ice, Cool to 4°C	14 days	12 days
Total Cyanide	1 1L plastic or glass bottle	Ice, Cool to 4°C, NaOH to pH>12	14 days	12 days
Ammonia	1 500-ml plastic bottle	2 mL H_2SO_4 per liter, ice, cool to 4°C.	28 days	26 days
TSS, TDS	1 500-ml plastic bottle	Ice, cool to 4°C.	7 days	7 days
Hardness	1 100-ml plastic bottle	pH<2, with HNO3, Ice, Cool to 4ºC	6 months	178 days
SVOCs	2 1-L amber bottle	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
Turbidity	1 500-ml plastic bottle	Ice, Cool to 4°C	48 hours	24 hours
TOC/COD	1 1-L amber bottle or 40-ml VOA vial for TOC	Ice, Cool to 4°C, with H_2SO_4 or HCl to pH<2	28 days	26 days
BOD	1 500-ml plastic bottle	Ice, Cool to 4°C	48 hours	24 hours
Pesticides	1 1-L amber bottle	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
PCBs	1 1-L amber bottle	Ice, Cool to 4°C	7/40 days[a]	5/40 days[a]
VOCs	3 40 mL VOA vials	pH<2, with HCl, Ice , Cool to 4°C	14 days[a] (7 days if unpreserved)	10 days[a] (5 days if unpreserved)
Total Kjeldahl Nitrogen (TKN)	1 1-L amber bottle	Ice, Cool to 4°C, with H_2SO_4 to pH<2	28 days	26 days
MEE	1 60-ml serum bottle w/ Teflon-lined cap	Ice, Cool to 4°C, 4°C trisodium phosphate for Method AM20GAX	14 days[a]	12 days[a]
Total Petroleum Hydrocarbons	1 1-L glass bottle	pH<2, with HCl, Ice , Cool to 4°C	7/40 days[a]	5/40 days[a]

Table 5-B

Sample Containers, Preservatives, and Holding Times for Aqueous Samples

Parameter	Sample Container	Preservative	Technical Holding Time [1]	Laboratory Holding Time [2]
TCLP VOC	3 40 mL VOA vials	Ice, Cool to 4°C	14/NA/14[b]	7/NA/7[b]
TCLP SVOC [c]	1 1-L amber bottle	Ice, Cool to 4°C	14/7/40 [b]	5/7/40 [b]
TCLP Mercury	1 1-L amber bottle	Ice, Cool to 4°C	28/NA/28 [b]	5/NA/28 [b]
TCLP Metals (except Mercury)	1 1-L amber bottle	Ice, Cool to 4°C	180/NA/180 [b]	178/NA/180 [b]

Notes:

1. Technical holding time between sample collection and sample analysis. Based on Region 2 SOPs, NYSDEC (2000) ASP, and method requirements.

2. Laboratory holding time requirement to meet technical holding time requirement. Holding time from Verified Time of Sample Receipt (VTSR) at the laboratory. Based on NYSDEC (2000) ASP and technical holding time requirement.

[a] number of days between sample collection and extraction / number of days between extraction and analysis;

[b] number of days between sample collection and TCLP extraction/number of days between TCLP extraction and preparative extraction/number of days between preparative extraction and analysis.

[c] TCLP SVOCs includes all semivolatiles, pesticides, and herbicides.

[d] Meet the laboratory holding time requirement does not automatically meet the technical holding time requirement. Special arrangement needed to meet the technical holding time requirement.

Table 6-A

Target Analyte List and Project ARAR/TBC Limits[1] for Volatile Organic Compounds by GC/MS – Water

Volatile Organic Compound	CAS #	CRQL for CLP Low Concentration TCL (OLC03.2/ASP2000) [2] ug/L	CRQL for CLP Water TCL (CLP OLM04.3/ASP 2000) [3] ug/L	Groundwater ARAR/TBC Value [4] ug/L	Surface Water ARAR/TBC Value [5] ug/L
Dichlorodifluoromethane	75-71-8	0.5	10	5	
Chloromethane	74-87-3	0.5	10	5	
Bromomethane	74-83-9	0.5	10	5	
Vinyl chloride	75-01-4	0.5	10	2	
Chloroethane	75-00-3	0.5	10	5	
Trichlorofluoromethane	75-69-4	0.5	10	5	
1,1-Dichloroethene	75-35-4	0.5	10	5	
1,1,2-Trichloro-1,2,2-trifluoroethane	76-13-1	0.5	10	5	
Acetone	67-64-1	5.0	10	50	
Carbon Disulfide	75-15-0	0.5	10	60	
Methyl Acetate	79-20-9	0.5	10		
Methylene chloride	75-09-2	0.5	10	5	200 (H)
trans-1,2-Dichloroethene	156-60-5	0.5	10	5	
Methyl tert-Butyl Ether	1634-04-4	0.5	10	10	
1,1-Dichloroethane	75-35-3	0.5	10	5	
Cis-1,2-Dichloroethene	156-59-2	0.5	10	5	
2-Butanone	78-93-3	5.0	10	50	
Chloroform	67-66-3	0.5	10	7	
1,1,1-Trichloroethane	71-55-6	0.5	10	5	
Cyclohexane	110-82-7	0.5	10		
Carbon tetrachloride	56-23-5	0.5	10	5	
Benzene	71-43-2	0.5	10	1	210
1,2-Dichloroethane	107-06-2	0.5	10	0.6	
Trichloroethene	79-01-6	0.5	10	5	40 (H)
Methylcyclohexane	108-87-2	0.5	10		
1,2-Dichloropropane	78-87-5	0.5	10	1	
Bromodichloromethane	75-27-4	0.5	10	50	
Cis-1,3-Dichloropropene	10061-01-5	0.5	10	0.4 [6]	
4-Methyl-2-pentanone	108-10-1	5.0	10		
Toluene	108-88-3	0.5	10	5	100
trans-1,3-Dichloropropene	10061-02-6	0.5	10	0.4 [6]	
1,1,2-Trichloroethane	79-00-5	0.5	10	1	
Tetrachloroethene	127-18-4	0.5	10	5	1 (H)
2-Hexanone	591-78-6	5.0	10	50	

Table 6-A

Target Analyte List and Project ARAR/TBC Limits[1] for Volatile Organic Compounds by GC/MS – Water

Volatile Organic Compound	CAS #	CRQL for CLP Low Concentration TCL (OLC03.2/ASP2000) [2] ug/L	CRQL for CLP Water TCL (CLP OLM04.3/ASP 2000) [3] ug/L	Groundwater ARAR/TBC Value [4] ug/L	Surface Water ARAR/TBC Value [5] ug/L
Dibromochloromethane	124-48-1	0.5	10	50	
1,2-Dibromoethane	106-93-4	0.5	10	0.0006	
Chlorobenzene	108-90-7	0.5	10	5	5
Ethyl Benzene	100-41-4	0.5	10	5	17
Total Xylenes	1330-20-7	0.5	10	5	65
Styrene	100-42-5	0.5	10	5	
Bromoform	75-25-2	0.5	10	50	
Isopropylbenzene	98-82-8	0.5	10	5	2.6
1,1,2,2-Tetrachloroethane	79-34-5	0.5	10	5	
1,3-Dichlorobenzene	541-73-1	0.5	10	3	5 [7]
1,4-Dichlorobenzene	106-46-7	0.5	10	3	5 [7]
1,2-Dichlorobenzene	95-50-1	0.5	10	3	5 [7]
1,2-Dibromo-3-chloropropane	96-12-8	0.5	10	0.04	
1,2,3-Trichlorobenzene	87-61-6	0.5	--	5	5 [8]
1,2,4-Trichlorobenzene	120-82-1	0.5	10	5	5 [8]
Bromochloromethane	74-97-5	0.5	--	5	

Notes:
1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. From CLP SOW for OLC03.2.
3. From CLP SOW for OLM04.3.
4. MCL, Secondary Drinking Water Regulations, or NYSDEC TOGS 1.1.1 for Class GA water, whichever is lower.
5. NYSDEC TOGS 1.1.1 for Class C water, or AWQC (USEPA, 2004) Criterion Continuous Concentration, whichever is lower. NYSDEC standards/guidelines for fresh water fish survival/propagation and wildlife protection were used; when not available, other standards/guidelines (human consumption of fish and aesthetic) were used.
   H – Human consumption of fish.
6. 0.4 ug/L applies to the sum of cis- and trans-1,3-dichloropropene.
7. Applies to the sum of 1,2-, 1,3- and 1,4-dichlorobenzene.
8. Applies to the sum of 1,2,3-, 1,2,4- and 1,3,5-trichlorobenzene.
-- Not on the CLP Low Concentration Organics TCL or CLP TCL.

Table 6-B

Target Analyte List and Project ARAR/TBC Limits[1] for Volatile Organic Compounds by GC/MS – Soil and Sediment

Volatile Organic Compound	CAS #	CRQL for CLP (CLP OLM04.3/ASP 2000) TCL [2] - Low Soil ug/kg	CRQL for CLP (CLP OLM04.3/ASP 2000) TCL [2] – Medium Soil ug/kg	NYSDEC TAGM [3] ug/kg	NYSDEC Sediment Screening Value [4] ug/kg

1,2-Dibromo-3-chloropropane	96-12-8	10	1200		
1,2,4-Trichlorobenzene	120-82-1	10	1200	3400	910 [6]

Notes:
1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. From CLP SOW for OLM04.3. The CRQLs for soil are based on 100% solids. Samples with less than 100% solids may have CRQLs greater than those listed in the table above.
3. From NYSDEC TAGM #4046.
4. From NYSDEC (1999) Technical Guidance for Screening Contaminated Sediments. Benthic aquatic life chronic toxicity for freshwater sediment was used and sediment was assumed to contain 1% organic carbon.
5. For dichlorobenzenes.
6. For trichlorobenzenes.
-- Not on the CLP Low Concentration Organics TCL or CLP TCL.

Table 6-C

Target Analyte List and Project ARAR/TBC Limits[1] for Semivolatile Organic Compounds by GC/MS – Water

Semivolatile Compound	CAS #	CLP OLC03.2 CRQL [2] ug/L	CLP OLM04.3 CRQL [3] ug/L	Groundwater ARAR/TBC Value [4] ug/L	Surface Water ARAR/TBC [5] ug/L
Benzaldehyde	100-52-7	5.0	10		
Phenol	108-95-2	5.0	10	1 [6]	5.0 [7]

Table 6-I

Target Analyte List and Project ARAR/TBC Limits[1] for Polychlorinated Biphenyls by GC/ECD - Water

PCB Compound	CAS #	CRQL for CLP Low Concentration TCL (OLC03.2/ASP2000) [2] ug/L	CRQL for CLP Water TCL (CLP OLM04.3/ASP 2000) [3] ug/L	Groundwater ARAR/TBC Value [4] ug/L	Surface Water ARAR/TBC Value [5] ug/L
Aroclor 1016	12674-11-2	0.20	1.0	0.09 [6]	$1.2x10^{-4}$ [6]
Aroclor 1221	11104-28-2	0.20	2.0	0.09 [6]	1.2x10
Aroclor 1232	11141-16-5	0.40	1.0	0.09 [6]	1.2x10
Aroclor 1242	53469-21-9	0.20	1.0	0.09 [6]	1.2x10
Aroclor 1248	12672-29-6	0.20	1.0	0.09 [6]	1.2x10
Aroclor 1254	11097-69-1	0.20	1.0	0.09 [6]	1.2x10
Aroclor 1260	11096-82-5	0.20	1.0	0.09 [6]	1.2x10

Notes:
1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. From CLP SOW for OLC03.2.
3. From CLP SOW for OLM04.3.
4. MCL, Secondary Drinking Water Regulations, or NYSDEC TOGS 1.1.1 for Class GA water, whichever is lower.
5. NYSDEC TOGS 1.1.1 for Class C water, or AWQC (USEPA, 2004) Criterion Continuous Concentration, whichever is lower. NYSDEC standards/guidelines for fresh water fish survival/propagation and wildlife protection were used; when not available, other standards/guidelines (human consumption of fish and aesthetic) were used.
6. Applies to the sum of PCB compounds.

Table 6-J

Target Analyte List and Project ARAR/TBC Limits[1] for Polychlorinated Biphenyls by GC/ECD – Soil and Sediment

PCB Compound	CAS #	CRQL for CLP (CLP OLM04.3/ASP 2000) TCL [2] ug/kg	NYSDEC TAGM [3] ug/kg	NYSDEC Sediment Screening Value [4] ug/kg
Aroclor 1016	12674-11-2	33	1000 (surface) 10000 (subsurface)	193
Aroclor 1221	11104-28-2	67	1000 (surface) 10000 (subsurface)	193
Aroclor 1232	11141-16-5	33	1000 (surface) 10000 (subsurface)	193
Aroclor 1242	53469-21-9	33	1000 (surface) 10000 (subsurface)	193
Aroclor 1248	12672-29-6	33	1000 (surface) 10000 (subsurface)	193
Aroclor 1254	11097-69-1	33	1000 (surface) 10000 (subsurface)	193
Aroclor 1260	11096-82-5	33	1000 (surface) 10000 (subsurface)	193

Notes:
1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. From CLP SOW for OLM04.3. The CRQLs for soil are based on 100% solids. Samples with less than 100% solids may have CRQLs greater than those listed in the table above.
3. From NYSDEC TAGM #4046.
4. From NYSDEC (1999) Technical Guidance for Screening Contaminated Sediments. Benthic aquatic life chronic toxicity for freshwater sediment was used and sediment was assumed to contain 1% organic carbon.

Table 6-K

Target Analyte List and Project ARAR/TBC Limits[1] for Inorganics – Water

Metal	CAS #	Contract Required Quantitation Level for ICP-AES[2] (µg/L)	Contract Required Quantitation Level for ICP-MS[2] (µg/L)	Groundwater ARAR/TBC Value [3] ug/L	Surface Water ARAR/TBC Value [4] ug/L
Aluminum	7429-90-5	500	50	50	100

Zinc	7440-66-6	75	10	2000	81
Cyanide	7440-67-7	20	--	200	1

Notes:

1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. From CLP SOW for ILM06.x.
3. MCL, Secondary Drinking Water Regulations, or NYSDEC TOGS 1.1.1 for Class GA water, whichever is lower.
4. NYSDEC TOGS 1.1.1 for Class C water, or AWQC (USEPA, 2004) Criterion Continuous Concentration, whichever is lower. NYSDEC standards/guidelines for fresh water fish survival/propagation and wildlife protection were used; when not available, other standards/guidelines (human consumption of fish and aesthetic) were used. A default hardness value of 100 ppm was assumed for ARAR/TBCs dependent on hardness.
5. When hardness is less than or equal to 75 ppm.
6. When hardness is greater than 75 ppm.
7. Applies for iron and manganese, respectively.
8. Applies to the sum of iron and manganese.

Table 6-L

Target Analyte List and Project ARAR/TBC Limits[1] for Inorganics – Soil and Sediment

Metal	CAS #	Contract Required Quantitation Level for ICP-AES[2] (mg/kg)	Contract Required Quantitation Level for ICP-MS[2] (mg/kg)	NYSDEC TAGM [3] mg/kg	NYSDEC Sediment Screening Value [4] mg/kg

Notes:

1. Project specific ARARs and TBCs may vary. This table lists commonly identified ARARs and TBCs for the Seneca project.
2. MCL, Secondary Drinking Water Regulations, or NYSDEC TOGS 1.1.1 for Class GA water, whichever is lower.
3. NYSDEC TOGS 1.1.1 for Class C water, or AWQC (USEPA, 2004) Criterion Continuous Concentration, whichever is lower. NYSDEC standards/guidelines for fresh water fish survival/propagation and wildlife protection were used; when not available, other standards/guidelines (human consumption of fish and aesthetic) were used.
4. From NYSDEC TAGM #4046.
5. From NYSDEC (1999) Technical Guidance for Screening Contaminated Sediments. Benthic aquatic life chronic toxicity for freshwater sediment was used and sediment was assumed to contain 1% organic carbon.
6. Reporting limit (RL) requirement for specific project may vary. See SS WP for project specific requirement.
7. Applies to NH3 + NH4 as N.
8. pH and temperature dependent. See NYSDEC TOGS 1.1.1 for details.
9. From NYSDEC Surface Water and Groundwater Quality Standards and Groundwater Effluent Limitations, 6 NYCRR Part 703.
10. Method quantitation limit.
11. Applies to the sum of nitrate and nitrite (expressed as N).
12. California Department of Health Services notification level.
13. Expressed as hydrogen sulfide.
14. USACE. 2002. Waste Management System; Testing and Monitoring Activities; Proposed Rule; Methods Innovation Rule

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Demonstrate acceptable analyst capability	Prior to using any test method and at any time there is a significant change in instrument type, personnel, or test method	QC acceptance criteria published by DoD, if available; otherwise method-specified criteria.	Recalculate results; locate and fix problem, then rerun demonstration for those analytes that did not meet criteria	Not applicable (NA)	This is a demonstration of ability to generate acceptable accuracy and precision using four replicate analyses of a QC check sample (e.g., LCS or PT sample). No analysis shall be allowed by analyst until successful demonstration of capability is complete.
Method detection limit (MDL) study	At initial set-up and subsequently once per 12 month period; otherwise quarterly MDL verification checks shall be performed	See 40 CFR 136B. MDL verification checks must produce a response at least 3 times greater than instrument's noise level.	Run MDL verification check at higher level and higher MDL set or reconduct MDL study	NA	Samples cannot be analyzed without a valid MDL.
Retention time window width calculated for each analyte and surrogate	At method set-up and after major maintenance (e.g., column change)	Width is ± 3 times standard deviation for each analyte retention time from 72-hour study.	NA	NA	

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Breakdown check (Endrin/ DDT Method 8081A only)	Daily prior to analysis of samples	Degradation < 20% for either endrin or DDT; Degradation <30% for sum of endrin and DDT.	Correct problem, then repeat breakdown check.	If DDT breakdown>20%:	No samples shall be run until degradation for individual compound DDT and endrin < 20% and degradation for combined DDT and endrin <30%.
Minimum three-point initial calibration for all analytes (ICAL)	Initial calibration prior to sample analysis. For HPLC, a five point initial calibration is required.	1) All single component analytes **except** alpha and delta BHC must have %RSD no greater than 20%. 2) Alpha and delta BHC must have %RSD no greater than 25%. 3) Surrogates must have %RSD no greater than 30%. 4) SOW allows up to **2** of single analytes except surrogates to fail contractual %RSD limit. **The failing analytes must have a %RSD < 30%.**	Correct problem, then repeat initial calibration.	If technical criteria were not met, qualify all associated positive results generated during the entire analytical sequence "J" and all non-detects "UJ". When %RSD > 90%, flag all non-detect results for that analyte "R" (unusable), and positive results as “J” estimated**.**	Problem must be corrected. No samples may be run until ICAL has passed. For PCB analysis, a mixture of Aroclors 1016 and 1260 is normally used to establish detector calibration linearity, unless otherwise specified by the SS-WP. In addition, a mid-level or lower standard for each of the remaining Aroclors is analyzed for pattern recognition and response factor.

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Second source calibration verification	Once after each initial calibration	Value of second source for all analytes within ± 25% of expected value (initial source)	Correct problem and verify second source standard. If that fails then repeat initial calibration.	If the %D is outside the ±25.0% range for any compound(s), qualify associated positive results for that compound "J" and non-detects "UJ". The "associated samples" are those which followed the last in-control standard up to the next passing standard containing the analyte(s) in question. If the %D is > 90%, flag all nondetects for that analyte "R" (unusable).	Problem must be corrected. No samples may be run until calibration has been verified.
Retention time window position establishment for each analyte and surrogate	Once per ICAL	The center of the retention time window shall be set at midpoint of initial calibration curve.	NA	NA	
Retention time window verification for each analyte and surrogate	Each calibration verification standard	All analytes and surrogates within established windows	Correct problem, then reprocess all samples analyzed since the last acceptable retention time check. Or, perform a new ICAL and reset retention time windows.	Flagging criteria is not appropriate for initial verification. For CCV, apply a Q-flag to all results for analytes outside the established window.	No samples shall be run without correctly set retention time windows.

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Calibration verification (initial [ICV] and continuing [CCV])	An instrument blank and the PEM must bracket one end of a 12-hour period during which sample data are collected, and a second instrument blank and the midpoint concentration of Individual Standard Mixtures A and B must bracket the other end of the 12-hour period.	All analytes within ± 25% of expected value (%D).	Correct problem, rerun calibration verification and reanalyze all samples since last successful calibration verification.	If the %D is outside the ±25.0% range for any compound(s), qualify associated positive results for that compound "J" and non-detects "UJ". The "associated samples" are those which followed the last in-control standard up to the next passing standard containing the analyte(s) in question. If the %D is > 90%, flag all nondetects for that analyte "R" (unusable).	If an individual analyte is > 25%, no samples may be analyzed until the problem has been corrected.
Method blank	A method blank must be extracted each time 20 or less field samples (excluding MS/MSD and PE samples) are extracted. A method blank shall be analyzed on each GC/EC system	No analytes detected ≥ CRQL and surrogate recoveries within 30%~150%.	Correct problem, if required, reprep then reanalyze method blank and all samples processed with the contaminated blank.	Flag sample result with a U if sample > CRQL but < or =5 x blank level; Report CRQL and qualify U if sample<CRQL and < or = 5 x blank level; no action if sample >CRQL and > 5 x CRQL.	

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Instrument blank	First analysis in a 12-hr analysis sequence	No analytes detected ≥ CRQL and surrogate recoveries within 30%~150%.	Correct problem, reanalyze instrument blank and associated samples.		
Laboratory control sample (LCS) containing all analytes required to be reported by the project or contract	One LCS for every group of samples in the Sample Delivery Group.	QC acceptance criteria specified in CLP and those specified in Table 9.	Correct problem, then reprep and reanalyze the LCS and all samples in the associated batch for failed analytes in all samples in the associated preparatory batch, if sufficient sample material is available	If corrective action fails, or sufficient sample volume is not available for reprep, apply professional judgment to determine necessary quailifier for specific analyte(s) in all samples in the associated preparatory batch.	LCS acceptance criteria MUST be met before data are reported. LCS contamination or any LCS analyzed not meeting the criteria will require re-extraction and re-analysis at no additional cost.
Matrix spike (MS)	A matrix spike must be performed for the following, whichever is most frequent: 1) Each SDG, 2) Each group of 20 field samples. 3) Each group of field samples of a similar concentration level.	For matrix evaluation, use QC acceptance criteria specified by CLP and those specified in Table 9.	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	No action is taken based upon MS/MSD data alone. MS/MSD results may be used in conjunction with other QC criteria to determine the need for data qualification. The validator using **professional judgment** has several options: 1) Do nothing; 2) Qualify only the affected analyte in the unspiked sample; 3) Qualify all analytes in the unspiked sample; 4) Qualify only the affected analyte in all samples. This must be supported by details; 5) Qualify only the affected analyte or all of the analytes if recovery is < 10%	For matrix evaluation only. If MS results are outside the limits, the data shall be evaluated to determine the source of difference and to determine if there is a matrix effect or analytical error.

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Matrix spike duplicate (MSD) or sample duplicate	A matrix spike duplicate or sample duplicate must be performed for the following, whichever is most frequent: 1) Each SDG, 2) Each group of 20 field samples, 3) Each group of field samples of a similar concentration level. For 8330, one laboratory duplicate should be submitted for each extraction batch.	RPD (between MS and MSD or sample and sample duplicate) meets criteria specified in Table 9.	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	Professional judgment, see above.	The data shall be evaluated to determine the source of difference.

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Surrogate spike (analytes identified in Table 8)	All field and QC samples	QC acceptance criteria for surrogate specified in Table 8	For QC and field samples, reanalyze sample. If surrogate recovery is still out, identify the cause of the problem. If possible, correct problem then reprep and reanalyze all failed samples for failed surrogates in the associated preparatory batch, if sufficient sample material is available. If obvious chromatographic interference with surrogate is present, reanalysis may not be necessary.	Qualify data in accordance with Region 2 SOP. In brief, 1) If surrogate on both columns is below limit but >10%, check chromatograms for interference and qualify affected analytes 2) If surrogate on both columns is below limit but > 10%, J non-detects and positive hits. 3) If recoveries for both surrogates on both columns are below limit but >10%, J positive results and UJ non-detects. 4) If recoveries are above limit for both surrogates on both columns, J positive values. 5) If both surrogates on one column are below limit but > 10%, use the data from the other column, providing both surrogates on that column are within limits. 6) If recovery is <10% for either surrogate on any column, and no chromatographic or matrix interference is visible, J positive results and R non-detects.	Alternative surrogates are recommended when there is obvious chromatographic interference.

Table 7-A
Quality Control Requirements for Organic Analysis by Gas Chromatography and High-Performance Liquid Chromatography
(Methods 7580, 8081A, 8082A, and 8330)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Confirmation of positive results (second column or second detector)	All analytes detected above the MDL require confirmation on a second column or second detector.	Results between two columns %D ≤ 25%. (when higher value is compared to lower value)	NA	Qualify data in accordance with Region 2 SOP. In brief, %D=0 - 25%, no action %D=26 - 70%, "J" %D=71 - 100%, "JN" %D=100-200% (No Interference) "R" %D=100 - 200% (Interference detected), "JN" %D> 50% (Pesticide value is < CRQL), "U" %D> 200% "R"	Report the lower of two results unless QA/QC issues with the column.
Results reported between MDL and RL	NA	NA	NA	Apply J to all results below CRQL. Hits well below the CRQLs (less than 1/2 the CRQL value) may be column/background noise and using discretion may not be reported.	

Note:
QA/QC requirements are based on the CLP OLM04.3 SOP. If SW 846 methods or other equivalent methods are chosen for specific project, QA/QC requirements should be consistent with the specifications provided by the method or the SS-WP. Data validation should be conducted in accordance with the Region 2 SOPs for the specific method.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Demonstrate acceptable analyst capability	Prior to using any test method and at any time there is a significant change in instrument type, personnel, or test method	QC acceptance criteria published by DoD, if available; otherwise method-specific criteria.	Recalculate results; locate and fix problem, then rerun demonstration for those analytes that did not meet criteria	NA	A demonstration of ability to generate acceptable accuracy and precision using four replicate analyses of a QC check sample (e.g., LCS or PT). No analysis shall be allowed until demonstration of capability is complete.
MDL study	At initial set-up and subsequently once per 12-month period; otherwise quarterly MDL verification checks shall be performed	See 40 CFR 136B. MDL verification checks must produce a response at least 3 times greater than instrument's noise level.	Run MDL verification check at higher level and higher MDL set or reconduct MDL study	NA	Samples cannot be analyzed without a valid MDL.
Tuning (MS methods only)	Prior to calibration and every 12 hours during analysis	Refer to Table 1 in Exhibit D of CLP OLC03.2 (December 2000) and OLM04.3 (March 2003) for specific requirements.	Retune instrument and verify. Rerun affected samples.	Flagging criteria is not appropriate	Problem must be corrected. No samples may be accepted without a valid tune.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Minimum five-point initial calibration for all analytes (ICAL)	Initial calibration prior to sample analysis, whenever corrective action is taken which may affect initial calibration, and whenever calibration acceptance criteria are not met.	Refer to CLP OLC03.2 (December 2000) and OLM04.3 (March 2003) for specific requirements. VOC: Table 5 in Exhibit D, OLM04.3; Table D-2 in Exhibit D, OLC03.2 SVOC: Table 5 in Exhibit D, OLM04.3; Table D-4 in Exhibit D, OLC03.2 Up to two compounds may fail the criteria and still meet the minimum RRF and %RSD requirements. However, these compounds must have a minimum RRF greater than or equal to 0.010, and the %RSD must be less than or equal to 40.0 percent.	Correct problem then repeat initial calibration.	Qualify in accordance with Region 2 SOP. If %RSD is > 30.0%, J associated detects. When %RSD is>90%, R non-detects and J detects**.** If the average RRF is < 0.05, qualify associated non-detects with an "R" and flag associated positive data as estimated "J".	Problem must be corrected. No samples may be run until ICAL has passed.
Retention time window position establishment for each analyte and surrogate	Once per ICAL	Position shall be set using the midpoint standard of the initial calibration curve.	NA	NA	
Evaluation of relative retention times (RRT)	Each calibration verification standard	All analytes and surrogates within established windows	Correct problem, then reprocess all samples analyzed since the last acceptable retention time check. Or, perform a new ICAL and reset retention time windows.	Professional judgment. If incorrect identifications were made, data should be rejected, flagged N or changed to not detected at reporting limit.	

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Calibration verification (CV)	Daily, before sample analysis, after injection of instrument performance compound and every 12 hours of analysis time	Refer to CLP OLC03.2 (December 2000) and OLM04.3 (March 2003). VOC: Table 5 in Exhibit D, OLM04.3; Table D-2 in Exhibit D, OLC03.2 SVOC: Table 5 in Exhibit D, OLM04.3; Table D-4 in Exhibit D, OLC03.2 Up to two compounds may fail the criteria and still meet the minimum RRF and %RSD requirements. These compounds must have a minimum RRF no less than 0.010, and %RSD must be less than or equal to 40.0 percent.	Correct problem, rerun CV. If that fails, then repeat initial calibration and reanalyze all affected samples.	J both detects and non-detects for the outlier compound(s) if %D>25%. When %D is > 90%, R non-detects and J detects**.** If any RRF is < 0.05, R associated non-detects and J associated detects.	
Internal standards	With every continuing calibration, and with every project sample	Internal standard areas of every sample and blank should be within the upper and lower limits (-50% to +100%) for each continuing calibration; the retention times of the internal standards should be within 30 seconds of the associated calibration standard.	Inspect mass spectrometer and GC for malfunctions. Reanalysis of samples analyzed while system was malfunctioning is mandatory. See corrective action for CV.	See Region 2 SOPs. If IS area count is outside limit, J associated results. Do not qualify nondetects when associated IS area counts are > 100%. If area counts are < 25% of 12-hr IS area, or if performance exhibits a major abrupt dropoff, R associated nondetects and J detects.	Sample results are not acceptable without a valid CV-IS.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Method blank	SVOC: One per preparatory batch (or 20 field samples, whichever is more frequent), VOC: analyzed every 12-hr time period on each GC/MS system, before any samples, and for each matrix.	The concentration of each target compound found in the storage and method blanks must be less than its CRQL, except for methylene chloride and cyclohexane which must be less than 10 times their respective CRQLs, acetone and 2-butanone, which must be less than two times their respective CRQLs, and phthalate esters, which must be less than 5 times CRQLs.	Correct problem. All samples processed within the 12-hour time period with a method blank or instrument blank that does not meet the blank technical acceptance criteria will require reanalysis at no additional cost.	For common analytes, flag sample result with a U if sample >CRQL but ≤10xblank level; Report CRQL and qualify U if sample<CRQL and ≤10xblank level; no action if sample >CRQL and >10xCRQL. For other analytes, flag sample result with a U if sample > CRQL but ≤5xblank level; Report CRQL and qualify U if sample<CRQL and ≤5xblank level; no action if sample >CRQL and >5xCRQL.	The source of the contamination must be investigated and appropriate corrective measures MUST be taken and documented before further sample analysis proceeds.
LCS containing all analytes required to be reported by the project or CLP	One LCS per preparatory batch	QC acceptance criteria specified by the laboratory or 70~130% when laboratory advisory limits are not available.	Correct problem, then reprep and reanalyze the LCS and all associated samples for failed analytes, if sufficient sample material is available.	When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.	When MS results indicate a potential problem due to sample matrix, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
MS	A matrix spike must be performed for the following, whichever is most frequent: 1) Each SDG, 2) Each group of 20 field samples, 3) Each group of field samples of a similar concentration level.	For matrix evaluation, use QC acceptance criteria specified by CLP and those specified in Table 9.	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	No action is taken based upon MS/MSD data alone. MS/MSD results may be used in conjunction with other QC criteria to qualify data. The validator using **professional judgment** has several options: 1) Do nothing 2) Qualify only the affected analyte in the unspiked sample 3) Qualify all of the analytes in the unspiked sample 4) Qualify only the affected analyte in all samples. This must have supporting details to document this action 5) Qualify only the affected analyte or all of the analytes if recovery is < 10%	For matrix evaluation only. If MS results are outside the limits, the data shall be evaluated to determine the source of difference and to determine if there is a matrix effect or analytical error.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
MSD or sample duplicate	A matrix spike duplicate or sample duplicate must be performed for the following, whichever is most frequent: 1) Each SDG, 2) Each group of 20 field samples, 3) Each group of field samples of a similar concentration level.	RPD (between MS and MSD or sample and sample duplicate) meets criteria specified in Table 9.	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	Professional judgment, see above.	The data shall be evaluated to determine the source of difference.

Table 7-B
Quality Control Requirements for Organic Analysis by Gas Chromatography/Mass Spectroscopy (Methods 8260B, 8270C, 524.2) and GC/FID (Method 8015B)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Surrogate spike (analytes identified in Table 8)	All field and QC samples	QC acceptance criteria for in Table 8.	For VOC, if any surrogate recovery fails, correct problem, then all samples with failing surrogates must be reanalyzed. For SVOC, if two or more surrogate within the same fraction fail, correct problem, then all samples with failing surrogates in the associated preparatory batch must be reprepped and /or reanalyzed.	For VOC, if recoveries ≥10% but outside limits, J all detects; UJ non-detects where recovery is less than lower limit. For SVOC, if two BN or acid surrogate recoveries exceed limits but ≥10%, for the affected fraction only, qualify positive results as J and flag all non-detects as UJ when recoveries are less than lower limit. For VOC and SVOC, If any surrogate recovery < 10%, qualify associated positive results as J and non-detects as R.	
Results reported between MDL and RL	NA	NA	NA	Apply J to all results between MDL and RL.	

Note:
QA/QC requirements are based on the CLP OLM04.3 SOP. If SW 846 methods or other equivalent methods are chosen for specific project, QA/QC requirements should be consistent with the specifications provided by the method or the SS-WP. Data validation should be conducted in accordance with the Region 2 SOPs for the specific method.

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Demonstrate acceptable analyst capability	Prior to using any test method and at any time there is a significant change in instrument type, personnel, or test method	QC acceptance criteria published by DoD, if available; otherwise method-specified criteria	Recalculate results; locate and fix problem, then rerun demonstration for those analytes that did not meet criteria	NA	This is a demonstration of analyst ability to generate acceptable accuracy and precision using four replicate analyses of a QC check sample (e.g., LCS or PT sample). No analysis shall be allowed by analyst until successful demonstration of capability is complete.
MDL study	At initial set-up and subsequently once per 12 months; otherwise quarterly MDL verification checks shall be performed	See 40 CFR 136B. MDL verification checks must produce a response at least 3 times greater than instrument noise level.	Run MDL verification check at higher level and higher MDL set or reconduct MDL study	NA	Samples cannot be analyzed without a valid MDL.
Instrument detection limit (IDL) study (ICP only)	Every 3 months	Detection limits established shall be ≤ CRDL.	NA	NA	Samples cannot be analyzed without a valid IDL.
Linear range or high-level calibration check standard (ICP only)	The upper limit of the linear range should be established prior to the start of contract analyses and at least quarterly thereafter.	NA	NA	NA	No samples may be analyzed without a valid upper limit of linear range established.

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Initial calibration for all analytes (ICAL)	Daily initial calibration prior to sample analysis (ICP: minimum one high standard and a blank; GFAA: minimum three standards and a blank; CVAA: minimum 4 standards and a blank)	ICP: No acceptance criteria unless more than one standard is used, in which case $r \geq 0.995$. GFAA: $r \geq 0.995$ CVAA: $r \geq 0.995$	Correct problem and repeat initial calibration.	Flag as J all associated results.	Problem must be corrected. No samples may be run until ICAL has passed.
Second source calibration verification	Once after each initial calibration, prior to sample analysis	All analyte(s) within ± 10% of expected value.	Correct problem and verify second source standard. If that fails, then repeat initial calibration.	J all detects with %R between 75-89% (65-79% for Hg; 70-84% for CN) or 111-125% (121-135% for Hg; 116-130% for CN) recovery. Qualify results <IDL as UJ if ICV %R is 75-89% (CN, 70-84%; HG, 65-79%). Reject data if recovery of the ICV is outside the range 75-125% (CN, 70-130%; Hg, 65-135%). Qualify five samples on either side of verification standard out of control limits.	Problem must be corrected. No samples may be run until calibration has been verified as acceptable.
Continuing calibration verification (CCV)	After every 10 samples and at the end of the analysis sequence	All analyte(s) within ± 10% of expected value	Correct problem, rerun calibration verification. If fails, repeat initial calibration and reanalyze samples.	Save as above.	Problem must be corrected. Results may not be reported without a valid CCV.

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Low level calibration check standard (ICP only)	Daily after ICV/ICB and immediately preceding the Interference Check Sample (ICS) analyses; in addition, at the end of each sample analysis run and at a frequency of not less than once per 20 analytical samples[1] per analysis run, followed by CCV/CCB.	The percent recovery of the CRI should fall within 70-130% (50-150% for antimony, lead, and thallium)	Reanalyze CRI, if still not within the limits, correct problem, recalibrate instrument, then reanalyze.	If the recovery of the standard is between 50-69%, flag all positive sample results as "J" and all non-detect results as "UJ"; If the recovery is between 131-150%, flag positive sample results as "J"; If the recovery is less than 50%, flag all data as "R"; If the recovery is greater than 150%, flag all positive sample results as "R".	No samples may be analyzed without a valid low-level calibration check standard. Low-level calibration check standard should be less than or equal to the reporting limit. If a multipoint calibration is performed and the low point of the calibration is at or below the reporting limit, no low level calibration check is necessary.

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Preparation blank	One per preparatory batch, or one per SDG, whichever is more frequent.	No analytes detected ≥ CRDL. For common laboratory contaminants, no analytes detected ≥ RL.	If preparation blank>CRDL, all associated samples with concentrations less than 10 times blank and above CRQL shall be redigested and re-analyzed. If preparation blank < -CRDL, all samples reported below 10 x CRDL associated with the blank, shall be redigested and re-analyzed with appropriate new QC.	Flagging criteria is not appropriate.	
Calibration blank	Immediately after every ICV and CCV, at a frequency of 10% or every 2 hours during the run, whichever is more frequent.	No analytes detected ≥ CRDL or 2xIDL if IDL > CRDL.	Correct problem, then reanalyze calibration blank and all associated samples.	Flag as (J) positive sample results when raw sample value is less than or equal to calibration blank value analyzed between calibration blank with value over CRDL (or 2xIDL) and nearest good calibration blank. Flag five samples on either side of the calibration blank outside limits.	

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Interference check solutions (ICP only)	At the beginning (after ICV) and end of an analytical run, and at a frequency of not less than once per 20 analytical samples per analysis run.	Within ±20% of true value	Terminate analysis, locate and correct problem, recalibrate instrument, reanalyze ICS, reanalyze all affected samples.	If ICS recovery is between 121-150%, flag associated positive sample results "J"; if ICS recovery falls within 50-79%, flag associated positive sample results as "J" and associated non-detect sample results as "UJ"; If ICS recovery is <50%, flag all associated results as "R"; if ICS recovery is > 150%, flag all positive results as "R".	
LCS containing all analytes required to be reported by the project or contract	One LCS per preparatory batch, or per SDG, whichever is more frequent for each matrix (aqueous and solid).	Within ±20% of true value for aqueous LCS. Within the USEPA specified limits for solid LCS provided by USEPA.	If % recovery for aqueous LCS falls outside 80 - 120% (exception: Ag and Sb), or if results for the solid LCS fall outside EPA limits, analyses must be terminated, problem corrected, and previous samples associated with the LCS redigested and reanalyzed..	If aqueous LCS recovery is < 50%, R all data; J associated data if LCS recovery is between 50% and 79%; J all detects if recovery is between 121% and 150%; R all detects if recovery is greater than 150%. If solid LCS recovery is higher than limits, J all associated detects. If solid LCS recovery is lower than limits, J all associated data.	

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Serial dilution test (ICP only)	One sample from each SDG and matrix.	Five-fold dilution must agree within ± 10% of the original measurement if concentration is sufficiently high (i.e., >10IDL).		J all sample data>10xIDLs (or >CRDL when 10xIDL<CRDL) for which %D is greater than 10% but less than 100%. R associated results no less than 10xIDLs (or >CRDL when 10xIDL<CRDL) for which %D is no less than 100%.	Only applicable for samples with concentrations > 10 x IDL.
Post digestion spike (ICP and cyanide)	When MS test fails.	Recovery within 75-125% of expected results	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	No action is taken based upon PDS data alone. However, using informed professional judgment, the PDS results may be used in conjunction with other QC criteria to determine the need for qualification of the data.	
Recovery test (GFAA only)	When dilution test fails.	Recovery within 85-115% of expected results.	Run samples by method of standard addition (MSA) or see flagging criteria.	Apply J to all sample results (for same matrix) in which MSA was not run when recovery is outside of 85-115% range.	
Method of standard addition (MSA)	When matrix interference is suspected	NA	NA	NA	Document use in the case narrative.

Table 7-C
Quality Control Requirements for Inorganic Analysis by Inductively Coupled Plasma (ICP) and Atomic Absorption Spectroscopy (AA) (Methods 6010B And 7000A Series)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
MS	One MS every 20 project samples, or per SDG, whichever is more frequent per matrix.	Recovery within 75-125% of expected results	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	For aqueous, if < 30%, R all associated results; if between 30-74%, J associated results, if between 126-150%, J associated detects; if >150%, R associated detects. For solid samples, if <10%, R associated data; if between 10-74%, J all associated data; if between 126-200%, J associated detects; if >200%, R associated detects.	For matrix evaluation only. If MS results are outside the limits, the data shall be evaluated to determine the source of difference and to determine if there is a matrix effect or analytical error.
MSD or sample duplicate	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	RPD < 20%, or difference <CRDL when both results<5CRDL(between MS and MSD or sample and sample duplicate)	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	For the specific analyte(s) in the parent sample, apply J if acceptance criteria are not met (RPD<50% for aqueous and RPD<100% for soil; difference<CRDL for aqueous and difference<2CRDL for soil when both concentrations <5CRDL).	The data shall be evaluated to determine the source of difference.
Results reported between IDL and CRDL	NA	NA	NA	Apply J to all results between IDL and CRDL.	

Note:
QA/QC requirements are based on the CLP ILM06.X SOP. If SW 846 methods or other equivalent methods are chosen for specific project, QA/QC requirements should be consistent with the specifications provided by the method or the SS-WP. Data validation should be conducted in accordance with the Region 2 SOPs for the specific method.

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Demonstrate acceptable analyst capability	Prior to using any test method and at any time there is a significant change in instrument type, personnel or test method	QC acceptance criteria published by DoD, if available; otherwise method-specified criteria	Recalculate results; locate and fix problem, then rerun demonstration for those analytes that did not meet criteria	NA	A demonstration of analyst ability to generate acceptable accuracy and precision using four replicate analyses of a QC check sample (e.g., LCS or PT). No analysis shall be allowed until demonstration of capability is complete.
MDL study	At initial set-up and once per 12 months for each digestion approach and instrument used, and after major instrument maintenance/ condition change.	See 40 CFR 136B. MDL verification checks must produce a response at least 3 times greater than instrument noise level.	Run MDL verification check at higher level and higher MDL set or reconduct MDL study.	NA	Samples cannot be analyzed without a valid MDL.
IDL study	Every 3 months	Detection limits established shall be ≤ CRDL.	NA	NA	Samples cannot be analyzed without a valid IDL.
Tuning (MS methods only)	Prior to initial calibration	Per 6020 (5.8) and CLP ILM05.3	Retune instrument then reanalyze tuning solutions.	Flagging criteria is not appropriate.	No analysis shall be performed without a valid MS tune.
Initial calibration (ICAL)	Daily prior to sample analysis, or after changes or corrections to the system. Minimum a high standard and a blank	If more than one calibration standard is used, $r \geq 0.995$	Correct problem, then repeat initial calibration.	Flag as J all associated results.	Problem must be corrected. No samples may be run until ICAL has passed.

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Second source calibration verification (ICV)	Once after each ICAL, prior to beginning a sample run	Value of second source for all analytes within ± 10% of expected value (initial source)	Correct problem and verify second source standard. If that fails, then repeat initial calibration.	Flag as J all positive data (not flagged with a "U") analyzed between a calibration verification with %R between 75-89% or 111-125% recovery and nearest good calibration standard. Qualify results <IDL as estimated (UJ) if the ICV is 75-89%. Reject data if recovery of the ICV is outside the range 75-125%. Qualify five samples on either side of verification standard out of control limits.	Problem must be corrected. No samples may be run until calibration has been verified.
Continuing calibration verification (CCV)	After every 10 samples and at the end of the analysis sequence	All analytes within ± 10% of expected value	Correct problem, rerun calibration verification. If that fails, then repeat initial calibration. Reanalyze all samples since the last successful calibration.	Flag as J all positive data (not flagged with a "U") analyzed between a calibration verification with %R between 75-89% or 111-125% recovery and nearest good calibration standard. Qualify results <IDL as estimated (UJ) if the ICV is 75-89%. Reject data if recovery of the CCV is outside the range 75-125%. Qualify five samples on either side of verification standard out of control limits.	Problem must be corrected. Results may not be reported without a valid CCV.

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Low-level calibration check standard (CRI)	Daily, after ICV/ICB and immediately preceding the Interference Check Sample (ICS) analyses. In addition, the lab shall analyze the CRI at the end of each sample analysis run and at a frequency of not less than once per 20 analytical samples[1] per analysis run. These subsequent analyses of the CRI shall be immediately followed by CCV/CCB analyses.	Within ± 30% of expected value (within ± 50% for cobalt, manganese, and zinc).	Correct problem, then reanalyze.	Flag as J all sample results within the affected range if the recovery of the standard is between 50-69%; flag only positive data within the affected range if the recovery is between 131-150%; reject all data within the affected range if the recovery is less than 50%; reject only positive data within the affected range if the recovery is greater than 150%. Qualify 50% of the samples on either side of CRI standard outside the control limits.	No samples may be analyzed without a valid low-level calibration check standard. Low-level calibration check standard should be less than or equal to the reporting limit.
Linear range or high-level calibration check standard	The upper limit of the linear range should be established prior to the start of contract analyses and at least quarterly thereafter.	NA	NA	NA	No samples may be analyzed without a valid upper limit of linear range established.

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Preparation blank	One per preparatory batch, or one per SDG, whichever is more frequent.	No analytes detected ≥ CRDL. For common laboratory contaminants, no analytes detected ≥ RL.	If preparation blank>CRDL, all associated samples with concentrations less than 10 times the blank concentration and above the CRQL shall be redigested and re-analyzed with appropriate new Quality Control (QC) for that analyte. If preparation blank < -CRDL, all samples reported below 10 x CRDL associated with the blank, shall be redigested and re-analyzed with appropriate new QC.	Flagging criteria is not appropriate.	No samples may be analyzed without an acceptable method blank.
Calibration blank	Immediately after every ICV and CCV, at a frequency of 10% or every 2 hours during the run, whichever is more frequent.	No analytes detected ≥ CRDL or 2IDL if IDL > CRDL.	Correct problem, then reprep and reanalyze calibration blank and previous 10 samples.	Flag as (J) positive sample results when raw sample value is less than or equal to calibration blank value analyzed between calibration blank with value over CRDL (or 2xIDL) and nearest good calibration blank. Flag five samples on either side of the calibration blank outside limits.	
Interference check solutions	The interference check solutions shall be	Within ±20% of true value, or ±3 times	Terminate analysis, locate and correct	If recovery is between 121-150%, flag all positive results	

Table 7-D

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
(ICS-A and ICS-AB)	analyzed at the beginning (after ICV) and end of an analytical run or twice during an 8-hour working shift, whichever is more frequent.	the CRQL, whichever is greater.	problem, recalibrate instrument, reanalyze ICS, reanalyze all affected samples.	"J"; If recovery falls within 50-79%, flag all results as "J"; If recovery is <50%, flag all results "R"; if ICS recovery is > 150%, flag all positive results as "R".	
LCS containing all analytes required to be reported by the project or contract	One LCS per preparatory batch, or per SDG, whichever is more frequent for each matrix (aqueous and solid)..	Within ±20% of true value for aqueous LCS. Within the USEPA specified limits for solid LCS provided by USEPA.	If % recovery for aqueous LCS falls outside 80 - 120% (exception: Ag and Sb), or if results for solid LCS fall outside EPA limits, analyses must be terminated, problem corrected, and previous samples associated with the LCS redigested and reanalyzed..	If aqueous LCS recovery is < 50%, R all data; if LCS recovery is between 50% and 79% J associated data; if recovery is between 121% and 150% J detects; if recovery is greater than 150% R all detects. If solid LCS recovery is higher than limits, qualify all associated positive data as J. If solid LCS recovery is lower than limits, J associated data.	
Serial dilution test	One sample from each SDG and matrix.	Five-fold dilution must agree within ± 10% of the original measurement if concentration is sufficiently high (i.e., >10IDL).		J associated sample data >10xIDLs (or >CRDL when 10xIDL<CRDL) for which percent difference is greater than 10% but less than 100%. R associated results no less than 10xIDLs (or >CRDL when 10xIDL<CRDL) for which %D is no less than 100%.	Only applicable for samples with concentrations > 10 x IDL.
Post digestion spike	When MS test fails.	Recovery within 75-125% of expected results	Examine project DQOs. Contact client for additional measures.	NA.	

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
MS	One MS every 20 project samples, or per SDG, whichever is more frequent per matrix.	Recovery within 75-125% of expected results	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	For aqueous, if < 30%, reject all associated aqueous data; if between 30-74%, flag all associated aqueous data as "J"; if between 126-150%, flag all positive sample results as "J"; if >150%, reject all positive sample results. For solid samples, if <10%, reject all associated data; if between 10-74%, flag all associated data as "J"; if between 126-200%, flag as "J" all positive sample results; if >200%, reject all positive sample results.	For matrix evaluation only. If MS results are outside the limits, the data shall be evaluated to determine the source of difference and to determine if there is a matrix effect or analytical error.
MSD or sample duplicate	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	RPD < 20%, or difference <CRDL when both results<5CRDL(between MS and MSD or sample and sample duplicate)	Examine the project-specific DQOs. Contact the client as to additional measures to be taken.	For the specific analyte(s) in the parent sample, apply J if acceptance criteria are not met (RPD<50% for aqueous and RPD<100% for soil; difference<CRDL for aqueous and difference<2CRDL for soil when both concentrations <5CRDL).	The data shall be evaluated to determine the source of difference.

Table 7-D
Quality Control Requirements for Trace Metals Analysis by Inductively Coupled Plasma Mass Spectrometry (Method 6020)

QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action	Data Validation Flagging Criteria	Comments
Internal standards (IS)	Every sample	IS intensity within 60-125% of intensity of the IS in the calibration blank	Original samples should be diluted by a factor of two, internal standards added, and the sample re-analyzed. Report the results of reanalysis if the internal standard responses are within the limits. If internal standard responses are still not within limits, note in SDG Narrative and report the results of the undiluted original sample analysis.	Flagging criteria is not appropriate.	No samples should be reported without passing internal standards.
Results reported between IDL and CRDL	NA	NA	NA	Apply J to all results between IDL and CRDL.	

Note:
QA/QC requirements are based on the CLP ILM06.X SOP. If SW 846 methods or other equivalent methods are chosen for specific project, QA/QC requirements should be consistent with the specifications provided by the method or the SS-WP. Data validation should be conducted in accordance with the Region 2 SOPs for the specific method.

Table 7-E
Quality Control Requirements for Perchlorate by Ion Chromatography (Method 314.0)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Initial Demonstration of Capability (IDC)	Prior to beginning any analysis batch.	See Table 5 of Method 314.0.	NA	
Matrix Conductivity Threshold (MCT)	As part of the initial demonstration of capability. See section 9.2.8 of Method 314.0.	MCT, based on linear regression, is the matrix conductance for which the peak area-to-height ratio percent difference exceeds 20%. See Table 5 of Method 314.0.	NA	
Method Detection Limit (MDL)	An MDL study is conducted at initial setup and subsequently once per 12-month period and when major changes occur in the methods operating procedures. If no changes have been made, quarterly MDL verification may be performed in lieu of yearly MDL study.	MDL study must be performed in the matrix of interest using a standard at a concentration that is 1 to 10 times the estimated MDL value. MDL must be validated through the analysis of a low-level spike at ~ 2 times MDL taken through the entire preparation process. MDL verification checks must produce a signal at least 3 times the instrument's noise level.	Run MDL verification check at higher level and set MDL higher or perform the MDL study again.	Samples cannot be analyzed without a valid MDL.
Limit of Quantitation (LOQ; called MRL, Method Reporting Level in 314.1)	With every initial calibration.	Documented in the specific matrix of concern, at or below the applicable regulatory limit. Equal to lowest calibration standard. At least 3 times the MDL/LOD. The LOQ must be verified in a solution prepared at the MCT.	Flag all results between LOD and LOQ as "J".	
Retention-Time	At method setup and after major maintenance (e.g., column change).	Width is + 3 times standard deviation for each analyte retention time from 72-hour study.	NA	

Table 7-E
Quality Control Requirements for Perchlorate by Ion Chromatography (Method 314.0)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Holding time (HT)	Applies to all samples.	HT < 28 days (to be consistent with other EPA requirements).	All data analyzed outside the required holding time should be qualified using professional judgment. If holding time is only slightly exceeded, data may be qualified with "J" or not at all. If holding time is grossly exceeded, data should be rejected (flagged as "R").	
Initial Calibration (ICAL)	Initial calibration prior to sample analysis.	Minimum of 5 calibration standards to establish linearity (daily), r2 > 0.995.	Correct problem, then repeat initial calibration. Flagging criteria are not appropriate.	Problem must be corrected. No samples may be run until ICAL has passed.
Second Source Calibration Verification (SSCV)	Once after each multipoint calibration.	Value of second source for perchlorate within + 10% of expected value (initial source).	Correct problem and verify second source standard. Rerun SSCV. If that fails, correct problem and repeat initial calibration.	Problem must be corrected. No samples may be run until SSCV has passed.
Initial Calibration Verification Standard (ICV)	After initial calibration, with each analysis batch, analysis of a standard at the LOQ	Recovery must be 85-115% of true value. Note: Method 314.0 requires + 25%; however, the DoD-QSM requires the acceptance criteria for the ICV to be the same as the continuing calibration verifications. As the QSM requirements are more stringent, they supersede the method requirements.	Correct problem and rerun ICV. If that fails, correct problem and repeat initial calibration. Flagging criteria are not appropriate. No samples may be run until calibration has been verified.	Problem must be corrected. No samples may be run until calibration has been verified.

Table 7-E
Quality Control Requirements for Perchlorate by Ion Chromatography (Method 314.0)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Instrument Performance Check (IPC)	One per analytical batch .Analysis of a standard containing mid-level perchlorate and interfering anions bracket each analytical batch to verify method performance at the matrix conductivity threshold. At least one IPC must be analyzed daily.	IPC conductance within + 10% of original measured value. Peak area-to-height ratio percent difference < 20% (compared to peak area-to-height ratio of the LCS). Perchlorate quantitated between 80 and 120% of fortified level. < 5% shift in perchlorate retention time.	Correct problem and then reanalyze all samples in that batch. If poor recovery from the cleanup filters is suspected, a different lot of filters must be used to re-extract all samples in the batch. If column degradation is suspected, a new column must be calibrated before the samples can be reanalyzed.	No samples may be reported as associated with a failing IPC.
Continuing Calibration Verification Standard (CCV)	Alternate analysis of mid-level standard and a standard at the LOQ after every 10 samples. At the end of the batch, both standards should be analyzed. All samples should be bracketed by the analysis of a standard demonstrating that the system was capable of accurately detecting and quantifying perchlorate.	Recoveries must fall between 85 and 115%.	Correct problem and rerun CCV and all samples analyzed since last successful CCV. If that fails, apply Q-flag to all results in all samples since the last acceptable calibration verification, if reanalysis is not possible.	No samples may be analyzed until the problem has been corrected.
Method Blank or Pretreated Laboratory Reagent Blank	One per batch (up to 20 samples). Must undergo same pretreatment process that was performed on the samples.	<½ of the RL	Correct problem, re-prep, then reanalyze method blank and all samples processed with the contaminated blank. Apply B-flag to all results for the specific analytes in all samples in the associated preparatory batch if reanalysis is unsuccessful.	N/A

Table 7-E
Quality Control Requirements for Perchlorate by Ion Chromatography (Method 314.0)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Pretreated QC	REQUIRED once per analytical batch if batch includes samples that have exceeded the MCT and have been pretreated in any way to reduce the common anion levels. Pretreated method blanks, LCS, ICS, and matrix spikes should be analyzed if any samples in the batch have required pretreatment to reduce common anions.	Apply criteria as stated above for individual QC elements.	Use corrective action/flagging criteria as stated above for individual QC elements.	Pretreated samples must have associated pretreated QC samples.
Laboratory Control Sample (LCS)	Once per analytical batch following the ICV. Calculate %Recovery prior to analyzing samples.	%Recovery within 85-115%.	Correct problem, then re-prep and reanalyze the LCS and all associated samples. If corrective action fails, all data should be rejected (flagged as "R")	Sample results from batches that fail the LCS are invalid.
Matrix Spikes (MS)	One per 20 samples per matrix.	%Recovery within 80-120%.	No action is taken based upon MS/MSD data alone. However, using informed professional judgment, the MS/MSD results may be used in conjunction with other QC criteria to determine the need for qualification of the data.	For matrix evaluation only. If MS results are outside limits, the data must be evaluated to determine the source of the difference and to determine if there is a matrix effect or analytical error.
Matrix Spike Duplicates or Laboratory Duplicates (MS and MSD)	one per 20 samples per matrix.	%Recovery within MS limits, RPD < 15%.	Flag all positive sample results as "J".	Evaluate the data to determine the source of the difference.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Holding Time (HT)	All samples	HT < 28 days	All data analyzed outside the required holding time should be qualified using professional judgment. If holding time is only slightly exceeded, data may be qualified with "J" or not at all. If holding time is grossly exceeded, data should be rejected (flagged as "R").	No criteria exist.
Limit of Quantitation (LOQ)	With every initial calibration.	Documented in the specific matrix of concern, at or below the applicable regulatory limit. Equal to lowest calibration standard. At least 3 times the MDL/LOD	Apply J-flag to all results between LOD and LOQ.	
Method Detection Limit (MDL)	A full MDL study is conducted at initial setup and subsequently once per 12-month period and when major changes occur in the method's operating procedures (addition of cleanup procedures, column changes, mobile phase changes). If no changes have been made to the method, quarterly MDL verification checks may be performed in lieu of the yearly MDL study.	MDL study must be performed in the matrix of interest using a standard at a concentration that is 1 to 10 times the estimated MDL value. MDL must be validated through the analysis of a low-level spike at ~ 2 times MDL taken through the entire preparation process. MDL verification checks must produce a signal at least 3 times the instrument's noise level.	Run MDL verification check at higher level and set MDL higher or re-conduct MDL study.	Samples cannot be analyzed without a valid MDL.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Retention Time (window width calculated for each analyte and internal standard)	At method setup and after major maintenance (e.g., column change).	Width is + 3 times standard deviation for each analyte retention time from 72-hour study.	N/A	N/A
Initial Calibration (ICAL)	Initial calibration prior to sample analysis.	Minimum of 5 calibration standards to establish linearity (daily), r2 > 0.995. The calibration is linear and shall not be forced through the origin.	Correct problem, then repeat initial calibration. Flagging criteria are not appropriate.	Problem must be corrected. No samples may be run until ICAL has passed.
Initial Calibration Verification Standard (ICV)	After initial calibration, daily analysis of a second source standard at the midpoint of the calibration.	%Difference < 15% relative to initial value.	Correct problem and rerun ICV. If that fails, correct problem and repeat initial calibration. Flagging criteria are not appropriate. No samples may be run until calibration has been verified.	Problem must be corrected. No samples may be run until calibration has been verified.
Continuing Calibration Verification Standard (CCV)	Analysis of mid-level standard after every 10 samples. All samples should be bracketed by the analysis of a standard, demonstrating that the system was capable of accurately detecting and quantifying perchlorate.	%Difference < 15% relative to initial value.	Correct problem and rerun CCV and all samples analyzed since last successful CCV. Flagging criteria are not appropriate. No samples may be run until calibration has been verified.	No samples may be analyzed until the problem has been corrected.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Method Detection Limit Verification Standard (MDLV)	Analysis of a standard containing perchlorate at 2 times the MDL concentration. This standard must be analyzed before and directly after every batch of samples is analyzed. It can be analyzed after every 10 samples in order to reduce the reanalysis rate.	Recovery within 30% of its true value.	Correct problem and rerun MDLV and all samples analyzed since last successful MDLV. Flagging criteria are not appropriate. No samples may be run until calibration has been verified.	No samples may be analyzed until the problem has been corrected.
Interference Check Sample (ICS)	Analysis of a standard containing perchlorate at the RL and interfering anions at the concentration determined by the interference threshold study. One ICS is extracted with every batch of 20 samples. It verifies the method performance at the matrix conductivity threshold (MCT). At least one ICS must be analyzed daily.	Monitor recovery of perchlorate and retention time. Recovery within 30%.	Correct problem and then reanalyze all samples in that batch. If poor recovery from the cleanup filters is suspected, a different lot of filters must be used to re-extract all samples in the batch. If column degradation is suspected, a new column must be calibrated before the samples can be reanalyzed.	No samples may be reported that are associated with a failing ICS.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Method Blanks (MB)	One per batch. Undergoes same pretreatment steps as the samples.	< ½ of the RL.	Correct problem, re-prep, then reanalyze method blank and all samples processed with the contaminated blank. If reanalysis fails criteria, flag all positive sample results within 5x the method blank concentration as "J".	
Laboratory Control sample (LCS)	Once per analytical batch spiked at the RL. Undergoes same pretreatment steps as the samples.	Recovery within method requirements or laboratory-generated limits, or 85-115% to verify calibration and to check method performance.	Correct problem, then re-prep and reanalyze the LCS and all associated samples. If corrective action fails, all data should be rejected (flagged as "R")	
Matrix Spikes (MS)	Collect one per 20 samples per matrix, spiked at the RL. Undergoes same pretreatment steps as the samples.	Recovery within 75-125%.	No action is taken based upon MS/MSD data alone. However, using informed professional judgment, the MS/MSD results may be used in conjunction with other QC criteria to determine the need for qualification of the data.	For matrix evaluation only. If MS results are outside the limits, the data must be evaluated to determine the source of the difference and to determine if there is a matrix effect or analytical error.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Matrix Spike Duplicates or Laboratory Duplicates (MS and MSD)	Collect one per 20 samples per matrix, spiked at the RL. Undergoes same pretreatment steps as the samples.	Recovery within MS limits, RPD < 20%.	Flag all positive sample results as "J".	Evaluate the data to determine the source of the difference.
Laboratory Reagent Blank	Analyzed prior to calibration and after samples with over-range concentration of perchlorate and after each batch is analyzed.	Concentration < ½ RL.	Reanalyze reagent blank (until no carryover is observed) and all samples processed since the contaminated blank. Apply J flag to all results not preceded by an acceptable reagent blank if reanalysis is not possible.	
QC Criteria Specific to MS Confirmation				
Mass Tuning	Daily before sample analysis.	Tuning standards should contain the analytes of interest.	Retune instrument. If the tune will not meet acceptance criteria, an instrument mass calibration must be performed and the tuning redone.	Sample analysis should not proceed without an acceptable tuning.
Mass Calibration	Performed prior to sample analysis and calibration curve analysis.	Mass calibration range must bracket the ion masses of interest. The most recent mass calibration must be used and the same mass calibration must be used for all data files in an analytical run. Acceptance criteria must be clearly stated in the laboratory's SOP.	If the mass calibration fails, recalibrate. If it still fails, consult manufacturer instructions on corrective maintenance.	No samples may be analyzed under a failing mass calibration.

Table 7-F
Quality Control Requirements for Perchlorate by MS Methods (Method EPA 331.0, EPA 332.0, SW6850)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Isotope Ratio 35Cl/37Cl	Every sample, spiked sample, and standard and method blank.	Monitor for both the parent ion at mass 99/101 and the product ion at mass 83/85 for MS-MS methods or just 99/101 for MS only. Theoretical ratio ~ 3.06. Must fall between 2.2 to 3.3.	If criteria are not met, sample must be rerun. If sample was not pretreated, sample should be re-extracted using cleanup procedures. If, after cleanup, ratio still fails, use alternative techniques to confirm presence of perchlorate (i.e., a post spike sample, dilution to reduce any interferences, etc.). Data should be qualified as J and should be noted in case narrative.	Decision to report data failing ratio check should be thoroughly documented in case narrative.
Internal Standard (IS)	Addition of 18O-labeled perchlorate to every sample, spiked sample, standard, instrument blank, and method blank.	Measured 18O IS area within + 50% of the value from the initial calibration (retention time window of ~ 0.3% for perchlorate and IS).	Rerun the sample at increasing dilutions until the + 50% acceptance criteria are met. If criteria cannot be met with dilution, the interferences are suspected and the sample must be re-prepped using further pretreatment steps. Data should be qualified as estimated with a J flag and should be discussed in the case narrative.	Use for quantitation and to ensure identification. Failing internal standard should be thoroughly documented in the case narrative.
Interference Threshold Study	At initial setup and when major changes occur in the method's operating procedures (addition of cleanup procedures, column changes, mobile phase changes).	Measure threshold of common suppressors (chloride, sulfate, carbonate, bicarbonate) that can be present in system without affecting quantitation of perchlorate. Threshold is concentration of the common suppressors where perchlorate recovery falls outside of 90-110% window.	N/A	This study and site history will determine the concentration at which the ICS suppressors

Table 7-G
Quality Control Requirements for Total Kjeldahl Nitrogen (TKN) (USEPA Method 351.2 / SM4500)

QC Element	Minimum Frequency	Criteria/Requirements	Corrective Action/ Flagging Criteria	Comments
Linear Calibration Range using three standards and a blank	every 6 months or significant change in instrument response	$\pm$ 10% linearity	Reestablish linearity, if range shown to be nonlinear, use sufficient standard to clearly define nonlinear portion.	J
Quality Control Sample	At the beginning of test (quarterly), or as required for data-quality	Concentrations $\pm$10% of stated values	Correct problem, reanalyze QCS. Repeat until concentrations within $\pm$ 10% of stated values	J
Method Detection Limit	every 6 months, when a new operator begins work, or significant change in instrument response	-		Flagging criteria not appropriate
Laboratory Reagent Blank	one per batch of samples	< MDL	Correct problem, repeat measurement	J
Laboratory Fortified Blank	one per batch of samples	Recovery between 90-110%	Correct problem, repeat measurement	J
Instrument Performance Check Solution	Checked daily following daily calibration, after every 10^{th} sample, and at the end of sample run	Within 10% of calibration. Peak Gaussian Factor between 0.8 and 1.15 to demonstrate proper instrument performance.	Retention times with a > 2% shift should be investigated and corrected. If column retention time noticeably shifts < 80% from original values, it should be cleaned or replaced.	J
Spike Duplicate	10% of field samples	Recovery between 90-110% 75-125%	Investigate if matrix influences are a factor.	J
Field or Laboratory Duplicate	5% of field samples, or one per sample batch	RPD $\leq$ 25% for aqueous and $\leq$ 50% for solids	Correct problem, repeat measurement	J

SW-846 Method 8081A and 8082A [3] Water and Soil			
In-house generated criteria or 70-130% when in-house criteria not available			

Notes:
1) For water matrix, limits based on Table D-3 from Draft OLC03.0, December 2000 and Table 3 in Exhibit D from OLM04.3, March 2003.
2) For soil matrix, limits based on Table 3 in Exhibit D from OLM04.3, March 2003.
3) For Method 8081A soil and water, limits based on Section 9.5.4 from Method 8000C.

Table 10-D
MS/MSD Control Limits for Inorganics

CLP ILM05.3, ILM06.X, SW 846 Method 6010B and 6020 Water and Soil[1]
75%-125%

Notes:
1) For water matrix, limits based on Table D-3 from Draft OLC03.0, December 2000 and Table 3 in Exhibit D from OLM04.3, March 2003.
2) For soil matrix, limits based on Table 3 in Exhibit D from OLM04.3, March 2003.
3) For Method 8081A soil and water, limits based on Section 9.5.4 from Method 8000C.

Table 10-E
MS/MSD Control Limits for Other Analytes [1]

Water Matrix			
Analyte	**Lower Control Limit (%)**	**Upper Control Limit (%)**	**RPD%**
Chloride, Sulfate and other Method 300.0 analytes	80	120	
Nitrate/Nitrite (Method 353.2)	90	110	
All other analytes for aqueous [2]	90	110	
All other analytes for solids [2]	75	125	

Notes:
1. Limits for LCS specified in the method were used as MS/MSD limits.
2. These limits will be used unless limits are provided by the analytical method or SS-WP.

TABLE 11
Field Equipment Calibration, Maintenance, Testing, and Inspection Summary

Field Equipment	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptable Criteria	Corrective Action	Responsible Party	Reference
Horiba U-22 Water Quality Meter Dissolved Oxygen	Manual calibration with 2 standards (zero and saturated)	Replace internal solution (monthly); Clean probes before storage. Replace DO Membrane. Replace Battery		Inspect sponge and replace as necessary (storage)	Morning and Evening	+/- 0.2 mg/L for 0.0 mg/L DO Standard	Replace DO membrane on probe.	Field Team Leader	See Appendix G
Horiba U-22 Water Quality Meter ORP	Manual calibration using standard solution	Replace Battery			Morning and Evening	Within 15 mV of solution	Recalibrate; Replace electrode or have meter inspected	Field Team Leader	See Appendix G
Horiba U-22 Water Quality Meter Temperature	Manual calibration using known temperature standard	Replace Probe; Replace Battery			Morning and Evening	+ / – 2 degrees	Recalibrate	Field Team Leader	See Appendix G
Horiba U-22 Water Quality Meter Conductivity	Auto calibration using a 4 pH standard solution	Replace Battery			Morning and Evening	+ /– 5%	Clean contacts on probe per owners manual	Field Team Leader	See Appendix G
Horiba U-22 Water Quality Meter pH	Auto calibration using a 4 pH standard solution	Replace Battery			Morning and Evening	+ / – 5%	Clean contacts on probe per owners manual; recalibrate with new solution	Field Team Leader	See Appendix G
MiniRae PID	Calibration with 2 points (zero and standard)	Clean PID Lamp and Filter (when zero creeps upward		Inspect filter for dust/foreign objects	Morning and Evening	+/- 2 ppm	Recalibrate	Field Team Leader	See Appendix G

TABLE 11
Field Equipment Calibration, Maintenance, Testing, and Inspection Summary

Field Equipment	Calibration Activity	Maintenance Activity or when in contact with moisture); check battery	Testing Activity	Inspection Activity	Frequency	Acceptable Criteria	Corrective Action	Responsible Party	Reference
Lamotte 2020 Turbidimeter Turbidity	Auto calibration using 2 standard solutions	Replace Lamp Replace Battery Repair	Standard check	Lamp display, battery	Morning and Evening	Display is stable, instrument function normal	Recalibrate, Replace Lamp Replace Battery Repair	Field Team Leader	See Appendix G
HACH Digital Titrator CO_2	Standard Check, Accuracy Check	Replace Reagent	Standard check, accuracy check		Morning and Evening		Rerun standard check	Field Team Leader	See Appendix G
HACH Colorimeter sulfate/sulfied, nitrite, alkalinity	Standard Check, Accuracy Check	Replace battery	Standard check, accuracy check		Morning and Evening		Rerun standard check	Field Team Leader	See Appendix G
HACH Spectrophotometer Ammonia	Calibration with 3 standard solutions	Replace Battery Repair	Standard check, accuracy check		Morning and Evening		Recalibrate, Replace Battery Repair	Field Team Leader	See Appendix G
HACH Hach DR/4000 1-Inch Cell Adapter Manganese	Calibration with 6 standard solutions	Replace Battery Repair	Standard check, accuracy check		Morning and Evening		Recalibrate, Replace Battery Repair	Field Team Leader	See Appendix G
HACH Ferrous iron	Calibration with 4 standard solutions	Replace Battery Repair	Standard check, accuracy check		Morning and Evening		Recalibrate, Replace Battery Repair	Field Team Leader	See Appendix G

Table 12
Performance Criteria for Field Duplicates and Laboratory Duplicates

Laboratory Duplicate		
	Frequency	RPD [1]
Metals (ILM05.3)	One per SDG, or 20 field samples in a SDG, or a group of field samples of a similar concentration level.	20% or CRDL
MEE	One per SDG, or 20 field samples in a SDG, or a group of field samples of a similar concentration level.	20% or RL
VOC/SVOC/Pesticides/PCBs (Matrix Spike Duplicate)	One per SDG, or 20 field samples in a SDG, or a group of field samples of a similar concentration level.	See Table 10
Explosives	One per extraction batch.	20%
Perchlorate	One per SDG, or 20 field samples in a SDG, or a group of field samples of a similar concentration level.	15%
Field Duplicate		
VOC/SVOC/Pesticides/PCBs, TCLP VOC/SVOCs	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	25% (water) 50% (soil)
Metals, TCLP Metals	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	50% or CRDL (water) 100% or CRDL (soil)
MEE	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	25% (water) 50% (soil)
Explosives	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	25% (water) 50% (soil)
Perchlorate, and other analytes	One every 20 project samples, or per SDG, whichever is more frequent, per matrix	25% (water) 50% (soil)

1. Refer to specific USEPA Region 2 SOPs for results close to reporting limits.

Table 13
QC Sample Types and Requirements

Sample Type	Purpose	Collection Requirement
	Field QC Sample	
Field Duplicate	To check reproducibility of laboratory and field procedures. To indicate non-homogeneity.	One every 20 project samples, or per SDG, per matrix
Trip Blank (VOC only)	To check contamination of VOC samples during handling, storage, and shipment from field to laboratory.	One per shipment; to be prepared prior to going into the field except for soil samples (no TB required).
Rinsate Blank	To check field decontamination procedures.	One per sampling event or one per 20 project samples whichever is more frequent, when sampling equipment is decontaminated and reused or when a sample collection vessel will be used..
MS/MSD (Organic Analysis Only)	To check accuracy and precision of organic analyses in specific sample matrices.	One per 20 project samples, generally conducted for samples with relatively high concentrations.
MS (Inorganics)	To check accuracy and precision of inorganic analyses in specific sample matrices.	One per 20 project samples, generally conducted for samples with relatively high concentrations.
	Laboratory QC Sample	
Laboratory QC sample requirement as specified in the specific analytical method.		

Notes:
1. This table presents general QC sample requirement based on previous experience at Seneca and the requirements specified in the following documents:
   (1) NYSDEC. 2001. Development and Review of Site Analytical Plans. March.
   (2) USEPA. 2004. Contract Laboratory Program Guidance for Field Samplers. August.
   (3) USEPA Region 2. 1989. CERCLA Quality Assurance Manual. October.
2. Project-specific QA sample requirement could be derived based on project-specific information; if different from above, the project-specific QA sample requirement should be specified in the SS-WP.

TABLE 14
Inspection/Acceptance Testing Requirements for Consumables and Supplies

Critical Supplies/ Consumables	Inspection/ Acceptance Specifications	Acceptance Criteria	Testing Method	Responsible Party	Handling/ Storage Conditions	Vendor
Isobutylene	Ensure container is pressurized	Visual	Used for PID calibration	Field Team Leader	None specified	Pine Environmental[1]
4 pH standard solution	Inspect for contamination periodically	Visual, or based on poor calibration results	Used for Horiba U-22 Auto calibration	Field Team Leader	None specified	Pine Environmental[1]
Powder for ORP standard solution			Used for Horiba U-22 ORP calibration	Field Team Leader	None specified	Pine Environmental[1]
Sodium hydroxide standard solution	Check fluid monthly for strength	5 – 5.25 mL of solution	Used for CO_2 Hach Titrator	Field Team Leader	None specified	Pine Environmental[1]
Reagent water	Check for evidence of tampering	Visual		Field Team Leader	None specified	Contracted laboratory

Note:
1 – Pine Environmental is the primary vendor used by Parsons for field equipment; other vendors may be utilized for the project.

Table 15
Critical Supplies and Consumables Tracking Log

Tracking Number	Date Received	Meets Inspection/Acceptance Criteria (Y/N, if yes include date)	Retesting Needed (Y/N, if yes include date)	Expiration Date	Initials/Date

Sample Trip Blanks	Field Team
Sample Duplicated	Field Team
Sample Disposal	
Sample Disposal	Field Analyst / Laboratory
Storage at Laboratory	Laboratory

Table 17
Summary of Calibration and QC Procedures for Screening Methods [a]

Method	Applicable Parameter	QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action [b]	Data Flagging Criteria
USEPA Method 160.3/160.1/ASTM D2216-90/D2216-05	Percent Solids	Field Duplicate	10% of field samples	RPD < 20%	Correct problem, repeat measurement	J
SW846 Method 1010A/1020B/1030	Ignitability	Field Duplicate	10% of field samples	RPD < 20%	Correct problem, repeat measurement	J
SW846 Method 1110	Corrosivity	Duplicate	10% of field samples	RPD < 20%	Correct problem, repeat measurement	J
SW846 Method 9040C with commercially available pH meter	pH (water)	2-point calibration required for each instrument	Once per day	± 0.05 pH units for every buffer	If calibration is not achieved, check meter, buffer solutions, and probe; replace if necessary; repeat calibration	Flagging criteria not appropriate
		pH 7 buffer	At each sample location	± 0.1 pH units	Correct problem, recalibrate	Flagging criteria not appropriate
		Field Duplicate	10% of field samples	± 0.1 pH units	Correct problem, repeat measurement	J
SW846 Method 9045D	pH (soil)	2-point calibration required for each instrument	Once per day	± 0.05 pH units for every buffer	Check with new buffer; if still out, repair meter, repeat calibration check	Flagging criteria not appropriate
		pH 7 buffer	At each sample location	± 0.1 pH units	Recalibrate	Flagging criteria not appropriate
		Field Duplicate	10% of field samples	± 0.1 pH units	Correct problem, repeat measurement. If still out, repeat calibration and reanalyze samples	J

Table 17
Summary of Calibration and QC Procedures for Screening Methods [a]

Method	Applicable Parameter	QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action [b]	Data Flagging Criteria
SW846 Method 9050A with commercially available conductivity meter	specific conductance	Calibration with KCl standard	Once per day at beginning of testing	± 5%	If calibration is not achieved, check meter, standards, and probe; repeat calibration	Flagging criteria not appropriate
		Field Duplicate	10% of field samples	± 5%	Correct problem, repeat measurement	J
USEPA Method 130.1	Hardness	Field Duplicate	10% of field samples	Burning rate within ± 10%	Correct problem, repeat measurement	J
USEPA Method 170.1 with commercially available thermometer	Temperature	Field Duplicate	10% of field samples	± 1.0 ˚C	Correct problem, repeat measurement	J
USEPA Method 180.1 with commercially available turbidity meter	Turbidity	Calibration with one formazin standard per instrument range used	Once per day at beginning of test	± 5 units, 0-100 range ± 0.5 units, 0-0.2 range ± 0.2 units, 0-1 range	If calibration is not achieved, check meter; replace if necessary, recalibrate	Flagging criteria not appropriate
		Field Duplicate	10% of field samples	RPD ≤ 20%	Correct problem, repeat measurement	J
E310.1/Hach Method 8203 or similar	Alkalinity	Field Duplicate	10% of field samples	RPD < 20%	Correct problem, repeat measurement	J
E360.1	Dissolved oxygen	Field Duplicate	10% of field samples	RPD < 20%	Correct problem, repeat measurement	J

Table 17
Summary of Calibration and QC Procedures for Screening Methods [a]

Method	Applicable Parameter	QC Check	Minimum Frequency	Acceptance Criteria	Corrective Action [b]	Data Flagging Criteria
Organic Vapor Analysis	Hydrocarbon vapor	Samples with elevated readings will be submitted for definitive analysis.				
Hach Methods		In accordance with Hach Method Reference. Field duplicate to be collected for 10% of field samples and RPD should be within 20%.				
ASTM D1498 with commercially available ORP instrument	Oxidation-reduction potential	Sensitivity verification	Daily	ORP should decrease when pH is increased	If ORP increases, correct the polarity of electrodes. If ORP still does not decrease, clean electrodes and repeat procedure.	Flagging criteria not appropriate
		Calibration with one standard.	Daily.	Two successive readings $\pm$10 millivolts	Correct problem, recalibrate	Flagging criteria not appropriate
		Field Duplicate	10% of field samples	$\pm$10 millivolts	Correct problem, repeat measurement	J

Notes:
a. If commercial instrument is used for the analysis, the calibration and QA/QC procedure shall be consistent with the manufacturer's manual or reference.
b. All corrective actions shall be documented, and the records shall be maintained by Parsons.
c. Please refer to SS-WP or specific analytical method for analysis not covered in this table.

Table 18-A. Inorganic Data Qualifier Flags

Data Qualifier	Definition
J	The associated value is an estimated quantity.
UJ	The material was analyzed for, but was not detected. The associated value is an estimate and may be inaccurate or imprecise.
R	The data was unusable. (Note: Analyte may or may not be present.).
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.

Table 18-B. Organic Data Qualifier Flags

Data Qualifier	Definition
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
N	The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."
NJ	The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Table 20
Summary of Data Validation Criteria [1]

Item	Criteria	Action
Holding Time and Sample Condition	Table 5-A/B of SAP	J data with exceedance, R data if limits grossly exceeded (e.g., exceeding 2 times of holding time).
Blank	No target analyte detected above method detection limit or reporting limit.	See Note 3.
Surrogate	Table 8 of SAP	if recovery>10% and upper limit, J all detects if recovery>10% but below lower limit, J all results if recovery<10%, J detects and R nondetects. [2]
Interference Check Sample (Inorganics Only)	80-120%	J associated detects if recovery is between 121-150%; J all sample results if recovery falls within 50-79%; R sample results for which recovery is less than 50%; R detects if ICS recovery is above 150%.
Instrument Performance Check	GC/MS instrument performance check criteria see specific method.	Professional judgment.
LCS/LCSD	Organics: Laboratory limits (or 70-130% when lab limits not available), others see Table 9 of SAP.	No action for organics based on LCS/LCSD only for organics. For all others, J all associated sample results if below lower limits; J all associated detects if above upper limits. R all data if LCS/LCSD recovery <50%. R all detects if LCS/LCSD recovery>150%.
Matrix Spike	Table 10 of SAP 80-120% (Method 300.0 for sulfate and chloride) 90-110% (Method 353.2 for nitrate and nitrite) 90-110% (all others in aqueous not specified in Method) 75-125% (all others in solids not specified in Method)	No action for organics based on MS/MSD only For all others, J all associated sample results if below lower limits; J all associated detects if above upper limits. [3]
Initial Calibration	CLP VOC/SVOC: %RSD=30%, RRF>=0.05 Method 8260B/8270C: %RSD=15%, RRF>=0.05 Method 524.2: %RSD=20%, RRF>=0.05 Pesticides/PCBs (CLP and SW 846 methods): %RSD=20%, RT within established window. Metals: initial calibration verification recovery within 90~110% (Hg 80~120%, CN 85~115%).	if %RSD>limit, J detects only. if %RSD>90%, R nondetects and J detects if RRF<0.05, R nondetects and J detects. For metals, if recovery > upper limit, J detects only. If recovery is between 75-89% (65-79% for Hg; 70-84% for CN) J all associated results. If recovery is outside the range 75-125% (CN, 70-130%; Hg, 65-135%), reject all associated results. Qualify five samples on either side of verification standard out of limits.
Continuing Calibration	CLP OLM04.3: %D=25%, RRF>0.05 Method 8260B/8270C: %D=20%, RRF>=0.05 CLP OLC03.2 and Method524.2: %D=30%, RRF>=0.05 Pesticides (CLP and SW 846 methods) and PCB (CLP): %D=25%, RT within established window, breakdown of DDT and endrin <=20%, combined breakdown<=30%. PCB (Method 8082): %D=15%, RT within established window. Metals: continuing calibration verification recovery within 90~110% (Hg 80~120%, CN 85~115%).	if %RSD>limit, J detects and UJ nondetects. if %RSD>90%, R nondetects and J detects if RRF<0.05, R nondetects and J detects [2] For metals, if recovery > upper limit, J detects only. If recovery is between 75-89% (65-79% for Hg; 70-84% for CN) J all associated results. If recovery is outside the range 75-125% (CN, 70-130%; Hg, 65-135%), reject all associated results. Qualify five samples on either side of verification standard out of limits.

Table 20
Summary of Data Validation Criteria [1]

Item	Criteria	Action
Contract Required Quantitation Limit Check Standard (Inorganics Only)	80-120%	J all results within affected range (for ICP within 2CRDL from standard, for CN within 50% of standard) if recovery is between 50-79%; J detects within affected range if recovery is between 121-150%; R all data within affected range if recovery is less than 50%; R detects within affected range if recovery is greater than 150%. Qualify 50% of the samples on either side of standard outside limits.
Analyte Results	For analytes measured using GC/MS, relative ion intensities should be consistent with the standards. RRT within 0.06RRT in the corresponding calibration or RT within the established window.	Professional judgment.
Internal Standards (Organics Only)	With the exception of Method 524.2 and CLP OLC03.2, the internal standard area response limits are -50% to +100% of the associated continuing calibration standard. Retention time within 0.50 minutes of internal standard RT for associated calibration. Method 524.2: internal standard recovery within -50% to +100% for each initial mid point calibration and -30% to +100% of the corresponding continuing calibration check. Retention time within 3 standard deviations of the mean retention compounds in the associated initial mid-point calibration standard. CLP OLC03.2: the internal standard area response limits are -40% to +40% of the associated continuing calibration standard. Retention time within 20 seconds of internal standard RT for associated calibration.	if recovery>25% and upper limit, J all detects if recovery>25% but below lower limit, J all results if recovery<25%, J detects and R nondetects. For CLP OLC03.2, see Region 2 SOP for actions. Professional judgment for RT exceedance.
ICP Serial Dilution (Metals Only)	Difference < 10%.	J all associated data for which %D is greater than 10% but less than 100%. R all associated sample results for which %D is greater than or equal to 100%. Qualify only results whose associated raw data are > 10xIDL (or > CRDL when 10xIDL< CRDL)
ICP Linear Range (Metals Only)	All raw sample results within the established ICP linear range.	J all results with associated raw results outside the ICP linear range.
Duplicates	See Table 12 of SAP if not specified, 25% for aqueous and 50% for solids	J the duplicate pair results. Professional judgment for results close to RL. [3]
Solids Percentage	>50%	J detects and UJ nondetects if solids percentage is less than or equal to 50% but greater than 10%. J detects and R nondetects if solids percentage is less than 10%.

Notes:
1. This table is a summary of data validation criteria and action based on the Region 2 SOPs. Refer to Region 2 SOPs (on-line resources available at http://www.epa.gov/region02/qa/documents.htm) for specific analytical method and any methods not included in this table.
2. For SVOCs, pesticides, and PCBs, refer to respective Region 2 SOPs for details.
3. See specific Region 2 SOPs.

TABLE 25
EQUIPMENT CHECKLIST FOR CORE SAMPLING

Health and Safety Items
Personnel protective equipment incluidng, but not limited to, the following:
Tyvek
Fulll face respirator and particulate cartridges
Disposable nitrile gloves (powderless)
Latex booties or yellow overboots
Hard hat
Steel-toed boots
Rain gear
Ear plugs
Field first aid kit
Decontamination Items
10 millimeter plastic sheeting
Aluminum foil
Rinse bottles
Alconox
2% Nitric acid
Isopropyl alcohol
Hexane
Paper towels
Deionized water provided by the laboratory
Carboy for potable water
Decontamination tubs (5-gallon buckets)
Long-handled brushes
Deionized water provided by the laboratory for field blanks
Paperwork
Field logbook and black ball point pens
Building Material Sampling Plan with appendices
Daily report forms
Site map
Chain-of-Custody records
Measuring Equipment
Folding ruler marked in tenths of an inch
Sampling Equipment
Pump-up sprayer and distilled water
Distilled Water
Portable coring drill
Diamond tipped coring bits and extensions
Wedge
Hammer
Castor dolly
Wet Vacuum
Food-grade Ziplpoc® bags (1-gallon each)
Packaging and shipping supplies
Clear packing tape
Duct tape
Custody Seals
Bubble wrap
Ice
Ziplpoc® bags (1-gallon each)

TABLE 25
EQUIPMENT CHECKLIST FOR CORE SAMPLING

Miscellaneous
Camera and film (35 millimeter) or digital camera
Flagging
Caution tape
Drum liners
Bung wrench/crescent wrench
Drums

5.0	Laboratory Management Capability	52

Section I - General Requirements

The Laboratory shall use proven instruments and techniques to identify and measure the concentrations of a variety of environmental parameters listed in Exhibit C. The Laboratory shall employ state-of-the-art analytical procedures to perform all analyses specified by the Contract Lab Sample Information Sheet (Figure #1 attached), including all necessary preparations for analysis.

1.0 Purpose

The New York State Department of Environmental Conservation (NYSDEC) in 1980 implemented a program to obtain analytical services from private analytical laboratories. The purpose of the program is to provide analytical data for use by NYSDEC in support of its investigation, clean-up, and monitoring activities under the Clean Water Act, the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) and the Superfund Amendments and Reauthorization Act of 1986 (SARA). In support of this program NYSDEC has developed this multi-media, multi-concentration Analytical Service Protocol (ASP).

2.0 Description of Service

The ASP provides a framework for laboratories to apply various USEPA analytical methods for the isolation, detection, and quantitative measurement of target compounds in water, soil/sediment, tissue, and hazardous waste environmental samples. The ASP provides methods that may be used, and the specific quality control and reporting requirements by which the laboratory will generate the data. This service uses a wide variety of analytical methods to analyze the target compounds.

3.0 Data Uses

This analytical service provides data which NYSDEC uses for a variety of purposes, such as determining the nature and extent of contamination at a hazardous waste site, assessing priorities for response based on risks to human health and the environment, determining appropriate cleanup actions, determining when remedial actions are complete, and determining compliance with regulatory permit limits and environmental standards. The data may be used in all stages in the investigation of a hazardous waste site, including site inspections, Hazard Ranking System scoring, remedial investigations/feasibility studies, remedial design, treatability studies, and removal actions. In addition, this service provides data that are available for use in enforcement/litigation activities.

4.0 Summary of Requirements

4.1 Introduction to the ASP. The ASP is designed as part of the documentation for a contract between NYSDEC and a commercial laboratory performing analyses in support of NYSDEC programs. The ASP is comprised of eight exhibits. Exhibit A provides an overview of the ASP and its general requirements. Exhibit B contains a description of the reporting and deliverables requirements, in addition to the data reporting forms and the forms instructions. Exhibit C specifies the target compound list for this ASP with the contract-required quantitation limits for

sample matrices. Exhibit D details the specific analytical procedures to be used with this ASP and resulting contracts. Exhibit E provides descriptions of required quality assurance/quality control (QA/QC), standard operating procedures, and procedures used for evaluating analytical methodologies, QA/QC performance, and the reporting of data. Exhibit F contains chain-of-custody and sample documentation requirements, which the Laboratory shall follow. To ensure proper understanding of the terms utilized in this ASP, a glossary can be found in Exhibit G (when a term is used in the text without explanation, the glossary meaning shall be applicable). Specifications for reporting data in computer-readable form appear in Exhibit H.

4.1.1 Exhibit D provides the Laboratory with the specific analytical procedures to be used and defines the specific application of these procedures to this contract. The procedures described are a compilation of methods required by several different monitoring programs and activities. The Laboratory shall utilize the appropriate program specified procedures for the analysis of each sample, based on information contained on the Contract Lab Sample Information Sheet. These procedures include instructions for sample preparation, screening, identification, quantification, and data evaluation. Where appropriate, specific ions used for searching the mass spectral data for each compound are included. The Laboratory shall perform sample preparation and analysis procedures as prescribed in Exhibit D, while meeting specified sample preservation and holding time requirements as specified in Exhibit I.

4.1.2 The Laboratory shall prepare necessary extracts, digestates, and dilutions of samples. The Laboratory shall screen organic extracts by methods of its choice (soil characterization mandatory; water characterization optional) at an initial extract concentration. Then, based on the screening response, the Laboratory shall use the specific analytical methods described in Exhibit D to extract and concentrate samples to achieve the Contract Required Quantitation Limits (CRQL) listed in Exhibit C. Exhibit D lists the analytical methods and starting points to be achieved for each parameter.

4.1.3 The Laboratory shall adhere to the quality assurance/quality control requirements specified in Exhibit E for all samples analyzed under this protocol.

4.1.4 During organic preparation, the Laboratory shall fortify all samples, blanks, matrix spikes, and matrix spike duplicates with the appropriate surrogate spiking compounds listed in Exhibits D and E. Additionally, all sample semivolatile extracts and aliquots for volatile organics analysis shall be spiked with the internal standard compounds listed in Exhibits D and E before injection or purging.

4.1.5 Additionally, for each sample analyzed by GC/MS, the Laboratory shall conduct mass spectral library searches to determine the possible identity of up to ten (10) volatile components and up to twenty (20) semivolatile components that are neither system monitoring compounds, surrogates, internal standards, or on the program specific volatile or semivolatile Target Compound List (TCL) (Exhibit C).

4.1.6 Exhibit F contains chain-of-custody and sample documentation requirements that the Laboratory must follow in processing samples under this

Protocol, and specifies requirements for written laboratory standard operating procedures.

4.1.7 Sample analysis, sample documentation, and other deliverables shall be reported as specified in Exhibit B. Specifications for reporting data in computer-readable format appear in Exhibit H.

4.1.8 To ensure proper understanding of language utilized in this Protocol, Exhibit G contains a glossary of terms. When a term is used in the text without explanation, the glossary meaning shall be applicable. Glossary definitions do not replace or take precedence over specific information included in the Protocol text.

4.1.9 The samples to be analyzed by the Laboratory may be from known or suspected hazardous waste sites and, potentially, may contain hazardous organic and/or inorganic materials at high concentration levels. The Laboratory should be aware of the potential hazards associated with the handling and analyses of these samples. It is the Laboratory's responsibility to take all necessary measures to ensure the health and safety of its employees.

4.1.10 In addition, the Laboratory must be aware of the importance of maintaining the integrity of the data generated under the Protocol as it is used to make major decisions regarding public health and environmental welfare. In addition, it may be used in litigation against potentially responsible parties in the enforcement of Superfund legislation.

4.1.11 In the vast majority of shipments, samples will be delivered directly to the laboratory facility by overnight delivery service. However, in the infrequent instance that it is necessary, the Laboratory shall be responsible for any handling or processing required for the receipt of sample shipments, including pickup of samples at the nearest servicing airport, bus station, or other carrier service within the laboratory's geographical area. The Laboratory shall pick up sample shipments within twenty-four (24) hours of notification.

4.1.12 Various Divisions within NYSDEC to fulfill workplan or consent order requirements may use any and all methods contained within this Protocol for direct contracting of laboratory services.

4.1.13 The Laboratory shall prepare sample containers in accordance with the specifications in Exhibit I, unless specifically directed to do otherwise by the Bureau of Watershed Assessment and Research (BWAR) or the Project Officer (PO).

4.1.14 Invoices for work performed under this Protocol as a direct analytical services contractor to NYSDEC **MUST** be submitted in the **EXACT** format shown in the example in Figure # 2 following. Invoices not in this format will be returned to the Laboratory for resubmission.

4.1.15 Prior to accepting any samples from the NYSDEC, the Laboratory shall have, in-house, the appropriate standards for all target compounds listed in Exhibit C.

4.2 Overview of Major Task Areas. For each sample, the Contractor shall perform the tasks described in this section. Specific requirements for each task are detailed in the exhibits as referenced.

4.2.1 Task I: Chain-of-Custody

4.2.1.1 Chain-of-Custody. The Laboratory shall receive and maintain samples under proper chain-of-custody procedures. All associated document control and inventory procedures shall be developed and followed. Documentation, as described therein, shall be required to show that all procedures are being strictly followed. This documentation shall be reported as the Complete Sample Delivery Group File (CSF) (see Exhibit B). The Laboratory shall establish and use appropriate procedures to handle confidential information received from the Agency. See Exhibit F for specific requirements.

4.2.1.2 Sample Scheduling/Shipments. Sample shipments to the Laboratory's facility will be scheduled and coordinated by the NYSDEC Bureau of Watershed Assessment and Research (BWAR) and or the Project Officer (PO). The Laboratory shall communicate with BWAR/PO personnel by telephone, as necessary throughout the process of sample scheduling, shipment, analysis, and data reporting, to ensure that samples are properly processed. At the time of sample scheduling, the Laboratory will be notified if the Modified SW-846 Method 5035 is to be used in the preparation and analysis of low level soil samples for volatiles.

4.2.1.2.1 Samples will be shipped routinely to the Laboratory through an overnight delivery service. However, as necessary, the Contractor shall be responsible for any handling or processing required for the receipt of sample shipments, including pick-up of samples at the nearest servicing airport, bus station, or other carrier service within the Laboratory's geographical area. The Laboratory shall be available to receive sample shipments at any time the delivery service is operating, including Saturdays.

4.2.1.2.2 If there are problems with the samples (e.g., mixed media, containers broken or leaking) or sample documentation/paperwork (e.g., Contract Laboratory Sample Information Sheets (CLSIS) not with shipment, sample and CLSIS numbers do not correspond), the Laboratory shall immediately contact BWAR/PO for resolution. The Laboratory shall immediately notify BWAR/PO regarding any problems and laboratory conditions that affect the timeliness of analyses and

data reporting. In particular, the Laboratory shall notify BWAR/PO personnel in advance regarding sample data that will be delivered late and shall specify the estimated delivery date.

4.2.1.2.3 To effectively monitor the temperature of the sample shipping cooler, NYSDEC may include a sample shipping cooler temperature blank with each cooler shipped. The temperature blank will be clearly labeled: NYSDEC COOLER TEMPERATURE INDICATOR.

4.2.1.2.3.1 When the NYSDEC supplies a cooler temperature indicator bottle in the sample shipping cooler, the Laboratory shall use the NYSDEC supplied cooler temperature indicator bottle to determine the cooler temperature. The Laboratory shall measure the temperature of the cooler at the time of sample receipt.

4.2.1.2.3.2 The temperature of the sample shipping cooler shall be measured and recorded immediately upon opening the cooler, and prior to unpacking the samples or removing the packing material.

4.2.1.2.3.3 To determine the temperature of the cooler, the Laboratory shall locate the cooler temperature indicator bottle in the sample shipping cooler, remove the cap, and insert a calibrated thermometer into the cooler temperature indicator bottle. Prior to recording the temperature, the Laboratory shall allow a minimum of 3 minutes, but not greater than 5 minutes, for the thermometer to equilibrate with the liquid in the bottle. At a minimum, the calibrated thermometer (±1°C) shall have a measurable range of 0 to 50 degrees Celsius. Other devices which can measure temperature may be used if they can be calibrated to ±1°C and have a range of 0 to 20°C. If a temperature indicator bottle is not present in the cooler, an alternative means of determining cooler temperature shall be used. However, under no circumstances shall a thermometer or any other device be inserted into a sample bottle for the purpose of determining cooler temperature. The Laboratory shall contact BWAR/PO and inform them that a temperature indicator bottle was not present in the cooler. The Laboratory shall document the alternative technique used to determine cooler temperature in the SDG Narrative.

4.2.1.2.3.4 If the temperature of the sample shipping cooler's temperature indicator exceeds 10 degrees Celsius, the Laboratory shall

contact BWAR/PO, inform them of the temperature deviation, and obtain instructions on how to proceed. The BWAR/PO will either require that no sample analysis(es) be performed or that the Laboratory proceed with the analysis(es). The Laboratory shall document the BWAR/PO decision in the SDG Narrative. Also in the SDG Narrative, the Laboratory shall list by fraction, the NYSDEC sample number of all samples, which were shipped in a cooler, which exceeded 10 degrees Celsius.

4.2.1.2.3.5 The Laboratory shall record the temperature of the cooler on the DC-1 Form, under Remark # 9 - Cooler Temperature, and in the SDG Narrative.

4.2.1.2.4 The Laboratory shall accept all samples scheduled by BWAR/PO, provided that the total number of samples received in any calendar month does not exceed the monthly limitation expressed in the contract. Should the Laboratory elect to accept additional samples, the Laboratory shall remain bound by all contract requirements for analysis of those samples accepted.

4.2.1.2.5 The Laboratory shall be required to routinely return sample shipping containers (e.g., coolers) to the appropriate sampling office within 14 calendar days following shipment receipt (see Clause entitled Government Furnished Supplies and Materials).

4.2.2 Task II: Analysis of Samples

4.2.2.1 Overview. - Sample analyses will be scheduled by groups of samples, each defined as a SDG and identified by a unique NYSDEC Case and SDG number assigned by BWAR. A Case number identifies to NYSDEC fiscal personnel the funding source that will be used in processing the sample invoice. An SDG signifies a group of samples collected at one site or geographical area over a finite time period, and will include one or more field samples with associated blanks. Samples may be shipped to the Laboratory in a single shipment or multiple shipments over a period of time, depending on the size of the SDG.

4.2.2.1.1 A Sample Delivery Group (SDG) is defined by the following, whichever is most frequent:

Each cooler of field samples received, OR

Each 20 field samples (excluding PE samples) within an SDG, OR

Each 7 calendar day period (excluding Sundays and Government holidays) during which field samples in an SDG are received (said period beginning with the receipt of the first sample in the SDG).

4.2.2.2 Preparation Techniques. The Laboratory will prepare samples as described in Exhibit D. For semivolatile and pesticide/Aroclor samples, an aliquot is extracted with a solvent and concentrated. The concentrated extract is subjected to fraction-specific cleanup procedures and then analyzed by GC/MS for semivolatile or GC/EC for the pesticide/Aroclor target compounds listed in Exhibit C. For volatile samples, an aliquot is purged with an inert gas, trapped on a solid sorbent, and then desorbed onto the GC/MS for analysis of the target compounds listed in Exhibit C.

4.2.2.3 Analytical Techniques. The target compounds listed in Exhibit C shall be identified as described in the methodologies given in Exhibit D. Automated computer programs may be used to facilitate the identification of compounds.

4.2.2.4 Qualitative Verification of Compounds. The volatile and semivolatile compounds identified by GC/MS techniques shall be verified by an analyst competent in the interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. This procedure requires the use of multiple internal standards.

4.2.2.4.1 If a compound initially identified by GC/MS techniques cannot be verified, but in the technical judgment of the mass spectral interpretation specialist the identification is correct, then the Laboratory shall report that identification and proceed with quantitation.

4.2.2.4.2 The pesticide/Aroclor compounds identified by GC/EC techniques shall be verified by an analyst competent in the interpretation of gas chromatograms and by comparison of the retention times of the suspected unknowns with the retention times of respective standards of the suspected compounds. Compounds shall also be confirmed by GC/MS techniques if the compounds are of sufficient concentration to be detected by the GC/MS.

4.2.2.5 Quantitation of Verified Compounds. The Laboratory shall quantitate components identified by GC/MS techniques by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall perform quantitation utilizing the internal standards specified in Exhibit D. The Laboratory shall quantitate components analyzed by GC/EC techniques by the external standard method stipulated in Exhibit D. The Laboratory shall also perform an initial three-point calibration, verify its linearity, determine the breakdown of labile components, and determine calibration factors for all standards analyzed by GC/EC techniques as described in Exhibit D.

4.2.2.6 Tentative Identification of Non-Target Sample Components. For each analysis of a sample, the Laboratory shall conduct mass spectral library searches to determine tentative compound identifications as follows: For each volatile sample, the Laboratory shall

conduct a search to determine the possible identity of up to 30 organic compounds of greatest concentration which are not system monitoring compounds or internal standards and are not listed in Exhibit C under volatiles or semivolatiles. For each semivolatile sample, the Laboratory shall conduct a search to determine the possible identification of up to 30 organic compounds of greatest concentration, which are not surrogates or internal standards and are not listed in Exhibit C under volatiles or semivolatiles. In performing searches, the NIST/EPA/NIH (May 1992 release or later) and/or Wiley (1991 release or later), or equivalent, mass spectral library shall be used.

NOTE: *Substances with responses less than 10% of the nearest internal standard are not required to be searched in this fashion.*

4.2.2.7 Quality Assurance/Quality Control Procedures. The Laboratory shall strictly adhere to all specific QA/QC procedures prescribed in Exhibits D and E. Records documenting the use of the protocol shall be maintained in accordance with the document control procedures prescribed in Exhibit F, and shall be reported in accordance with Exhibit B and Exhibit H.

4.2.2.7.1 The Laboratory shall maintain a Quality Assurance Plan (QAP) with the objective of providing sound analytical chemical measurements. This program shall incorporate the quality control procedures, any necessary corrective action, and all documentation required during data collection as well as the quality assessment measures performed by management to ensure acceptable data production.

4.2.2.7.2 Additional quality control shall be conducted in the form of the analysis of laboratory evaluation samples submitted to the Laboratory by the NYSDEC. The results of all such quality control or laboratory evaluation samples may be used as the basis for an equitable adjustment to reflect the reduced value of the data to the NYSDEC or rejection of data for: sample(s), a fraction within an SDG, or the entire SDG, and/or may be used as the basis for contract action. "Compliant performance" is defined as that which yields correct compound identification and concentration values as determined by the NYSDEC, as well as meeting the contract requirements for analysis (Exhibit D), quality assurance/quality control (Exhibit E), data reporting and other deliverables (Exhibits B and H), and sample custody, sample documentation, and standard operating procedure documentation (Exhibit F).

4.2.2.8 The Laboratory may be requested by NYSDEC to perform modified analyses. These modifications may include, but are not limited to, additional compounds, sample matrices other than soil/sediment or water, and lower quantitation limits. These requests will be made by the BWAR/PO in writing, prior to sample scheduling. If the Laboratory voluntarily elects to perform these modified analyses, these analyses will

be performed at a price agreed to by BWAR/PO. In addition, all applicable requirements specified in the Protocol will remain in effect.

4.2.3 Task III: Reporting Requirements

4.2.3.1 EPA has provided the Laboratory with formats for the reporting of data (Exhibits B and H). The Laboratory shall be responsible for completing and submitting analysis data sheets and computer-readable data on diskette (or via an alternate means of electronic transmission approved in advance by the NYSDEC) in the format specified in this Protocol and within the time specified in the Contract Performance/Delivery Schedule in Exhibit B.

4.2.3.2 Use of formats other than those designated by NYSDEC will be deemed as noncompliant. Such data are unacceptable. Resubmission in the specified format at no additional cost to the NYSDEC shall be required.

4.2.3.3 Computer-generated forms may be submitted in the hardcopy data package(s) provided that the forms are in **exact NYSDEC format**. This means that the order of data elements is the same as on each NYSDEC-required form, including form numbers and titles, page numbers, and header information.

4.2.3.4 The data reported by the Laboratory on the hardcopy data forms and the associated computer-readable data submitted by the Laboratory shall contain identical information. If discrepancies are found during government inspection, the Laboratory shall be required to resubmit either the hardcopy forms or the computer-readable data, or both sets of data, at no additional cost to the NYSDEC.

4.3 Technical and Management Capability

4.3.1 Personnel. The Laboratory shall have adequate personnel at all times during the performance of the contract to ensure that NYSDEC receives data that meet the terms and conditions of the contract and Protocol.

4.3.2 Instrumentation. The Laboratory shall have sufficient gas chromatograph/electron capture/data system (GC/EC/DS), gas chromatograph/mass spectrometer/data system (GC/MS/DS), including magnetic tape storage devices, and gel permeation chromatography system (GPC) capability to meet all the terms and conditions of the contract and Protocol.

4.3.3 Facilities. The Laboratory shall maintain a facility suitable for the receipt, storage, analysis, and delivery of the product meeting the terms and conditions of the contract and Protocol.

Section II - Specific Requirements

1.0 Introduction

The Laboratory shall receive and handle samples under the chain-of-custody and sample documentation procedures described in Exhibit F. Any discrepancies in documents or missing information is to be immediately brought to the attention of the BWAR/PO. A sample consists of all components, perhaps more than one phase, contained inside appropriate receptacles. More than one container may be used for a single sample; individual containers may contain preservatives for different analysis portions. Containers may be glass or plastic.

The Laboratory shall provide the required analytical expertise and instrumentation for analyses of the listed environmental parameters equal to or lower than the quantitation limits specified in Exhibit C. In Exhibit D, NYSDEC provides the laboratory with the specific sample preparation techniques and analytical procedures to be used along with a procedural rationale, and a schematic flow chart depicting the complete low level-medium level analytical scheme.

The Laboratory shall prepare and analyze samples within the maximum holding time specified in Exhibit I even if these times are less than the maximum 30-day completion time allowed in this Protocol.

****
* Note: The Laboratory is advised that the samples received under *
* this Protocol are often from known or suspected hazardous *
* waste sites and may contain higher (greater than 15%) levels *
* of organic and inorganic materials of a potentially hazardous *
* nature and of unknown structure and concentration and *
* should be handled throughout the analysis with appropriate *
* caution. It is the Laboratory's responsibility to take all *
* necessary measures to ensure laboratory safety. *
****

Methods for preparation of aqueous and solid samples are prescribed in Exhibit D.

For each sample received, the Laboratory may be required to perform any or all of the analyses described in Exhibit D in this Protocol. (The documentation that accompanies the sample(s) to the laboratory facility shall indicate specific analytical requirements for that sample or set of samples, by task and/or by specific target parameters.)

For the purpose of this Protocol, the analysis of a sample is defined as any, or all, of the tasks and constituents identified in Exhibits C and D, and related QA/QC as specified in Exhibit E.

***Note**: All QA/QC requirements are an inherent part of this Protocol requirement and are included in any contract bid price. The only exception being that specifically designated external QA/QC samples such as matrix duplicates, matrix spikes, matrix spike duplicates, matrix spike blanks, Laboratory Control Samples, and trip blanks are separate billable samples.*

Sample shipments to the Laboratory's facility will be scheduled and coordinated by the NYSDEC BWAR/PO.

The Laboratory shall communicate with NYSDEC authorized personnel by telephone as necessary throughout the process of sample scheduling, shipment, analysis and data reporting, to ensure that samples are properly processed. This shall include immediately notifying BWAR or the Project Officer of any irregularities with samples or sample paperwork received (noting discrepancies from verbal order placed by NYSDEC authorized personnel, problems encountered in sample analyses that will affect the data produced, and laboratory conditions that impact on timeliness of analyses and data reporting. In particular, the Laboratory shall notify BWAR in advance regarding sample data that will be late and shall specify an estimated delivery date.

Each sample received by the Laboratory should be labeled with a NYSDEC sample number, and accompanied by a Contract Lab Sample Information Sheet bearing the sample number and descriptive information regarding the sample. The Laboratory shall complete and sign the Chain-of-Custody received with the sample, recording the date of sample receipt and sample condition on receipt for each sample container. The Laboratory shall initiate an internal Chain-of-Custody for all samples submitted under this Protocol that will track the sample throughout the Laboratory. The Laboratory shall submit the signed copy of each Chain-of-Custody to BWAR with the sample data package (see contract delivery schedule). If there are problems either with the samples (e.g., mixed media, containers broken or leaking) or paperwork (e.g. Contract Lab Sample Information Sheet not with shipment; samples and sample numbers do not correspond) the Laboratory shall immediately contact BWAR for resolution.

The NYSDEC sample numbers shall be used by the Laboratory in identifying samples received under this protocol both verbally and in reports/correspondence.

The Laboratory shall accept all samples scheduled by NYSDEC provided that the total number of samples received in any calendar month does not exceed the monthly limitation expressed in the contract. Should the Laboratory elect to accept additional samples, the Laboratory shall remain bound by all contract requirements for analysis of those samples accepted.

The following are program specific requirements:

2.0 Superfund-CLP Inorganics

Analyze Samples for Identity and Quantitation of Specific Inorganic Constituents.

2.1 For each sample received, the Laboratory may be required to perform the analyses described in paragraphs 2.2, 2.3, and 2.4 following. The documentation that accompanies the sample(s) to the laboratory facility shall indicate specific analytical requirements for that sample or set of samples.

2.2 Exhibit D, CLP, Inorganics specifies the analytical procedures that must be used. It includes instructions and references for preparation of samples containing low-to-medium concentrations of inorganics for ICP analysis; flame, graphite furnace and cold vapor AA analysis; and cyanide analysis. The identification and quantitation of analytes other than cyanide shall be accomplished using the ICP or AA methods specified in Exhibit D, CLP, Inorganics whichever method will achieve the Contract

Required Quantitation Limit (CRQL) in Exhibit C. Cyanide shall be analyzed by the individual procedures specified in Exhibit D, CLP, Inorganics.

2.3 All samples must initially be run undiluted (i.e., final product of sample preparation procedure). When an analyte concentration exceeds the calibrated or linear range, appropriate dilution and reanalysis of the prepared sample is required, as specified in Exhibit D, CLP, Inorganics.

2.4 For the purpose of this protocol, a full sample analysis is defined as analysis for any or all of the (CLP-TCL) consitituents identified in Exhibit C as specified by the Contract Lab Sample Information Sheet in accordance with the methods in Exhibit D and performance of related QA/QC as specified in Exhibit E. Duplicate sample, laboratory control sample, and spike sample analyses shall each be considered a separate full sample analysis. All other QA/QC requirements are considered an inherent part of this Protocol and are included in the contract sample unit price.

3.0 Superfund-CLP Organics

The Laboratory shall use its analytical experience and equipment to perform qualitative and quantitative analyses of the TCL organic chemical pollutants listed in Exhibit C. Preparation of the samples shall be done as described in Exhibit D, CLP, Organics. The Laboratory shall follow the protocols established by the NYSDEC for sample preparation, analysis, storage and preservation before and after the analysis (see Exhibit D, CLP, Organics).

During preparation, the Laboratory shall fortify all samples, blanks, matrix spikes, and matrix spike duplicates with surrogate spiking compounds (listed in Exhibit E). Additionally, all sample semi-volatile extracts and aliquots for volatile organics analysis shall be spiked with internal standard compounds (listed in Exhibit E) before injection or purging.

In Exhibit D, CLP, Organics, the NYSDEC provides the Laboratory with the specific analytical procedures to be used along with the definition of the specific application of these methods to this Protocol. This includes instructions for sample preparation, gas chromatographic screening, mass spectrometric identification and data evaluation. Specific ions used for searching the mass spectral data for each compound are included.

For each sample, the Laboratory shall perform the following:

3.1 Receive and Prepare Hazardous Waste Samples

3.1.1 Receive and handle samples under chain-of-custody procedures described in Exhibit F.

3.1.2 Prepare samples as described in Exhibit D. VOA analysis of water or soil samples must be completed within **10 (TEN)** days of VTSR (Validated Time of Sample Receipt). Separatory funnel extractions for pesticides in water samples must be completed within **5 (FIVE)** days of VTSR. Sonication extractions for pesticides and/or semivolatiles in soil samples must be completed within **5 (FIVE)** days of VTSR. Continuous liquid-liquid extraction for semivolatile samples

must be started within **5 (FIVE)** days, and completed within **7 (SEVEN)** days of VTSR.

Extracts of either water or soil samples must be analyzed within 40 days of extraction. This does not release the Laboratory from the contract or work plan specified data turnaround time.

3.2 Extraction and Analysis for Identification of Specific Organic Compounds.

3.2.1 Extracts and diluted aliquots prepared in paragraph 3.1. shall be analyzed by GC and GC/MS techniques given in Exhibit D, CLP, Organics for the CLP-TCL substances referenced in Exhibit C as specified by the Contract Lab Sample Information Sheet.

3.2.2 The target compounds listed in CLP-TCL, Exhibit C, shall be identified as described in the methodologies given in Exhibit D, CLP, Organics. Automated computer programs may be used to facilitate the identification.

3.3 Qualitative Verification of the Compounds Identified in Section 3.2.

3.3.1 The compounds analyzed by GC/MS techniques and initially identified in Section 3.2 shall be verified by an analyst competent in the interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. Two criteria must be satisfied to verify the identifications:

3.3.1.1 Elution of the sample component at the same GC relative retention time as the standard component, and

3.3.1.2 Correspondence of the sample component and standard component mass spectra.

3.3.2 For establishing correspondence of the GC relative retention time (RRT), the sample component RRT must compare within ±0.06 RRT units of the RRT of the standard component. For reference, the calibration standard must be run on the same 12-hour time period as the sample.

For comparison of standard and sample component mass spectra, mass spectra obtained on the Laboratory's GC/MS are required. Once obtained, these standard spectra may be used for identification purposes only if the Laboratory's GC/MS meets the DFTPP or BFB daily tuning requirements of Tables 1.1 and 1.2 in Exhibit E. The standard spectra used may be from a laboratory generated library or obtained from the calibration standard run used to obtain reference RRTs. The requirements for qualitative verification by comparison of mass spectra are as follows:

3.3.2.1 All ions present in the standard mass spectrum at a relative intensity greater than 10 percent (most abundant ion in the spectrum equals 100 percent) must be present in the sample spectrum.

3.3.2.2 The relative intensities of ions specified in 3.3.2.1 must agree within plus or minus 20 percent between the standard and sample spectra.

3.3.2.3 Ions greater than 10 percent in the sample spectrum but not present in the standard spectrum must be considered and accounted for by the analyst making the comparison. When GC/MS computer data processing programs are used to obtain the sample component spectrum, both the processed and the raw spectra must be evaluated. The verification process should favor false positives.

3.3.3 If a compound analyzed by GC/MS techniques and initially identified in Section 3.2 cannot be verified by all of the criteria in items 3.3.1 and 3.3.2 above, but in the technical judgment of the mass spectral interpretation specialist the identification is correct, then the Laboratory shall report that identification, and proceed with quantification in Section 3.4.

3.3.4 The pesticide/Aroclor compounds listed in Exhibit C and analyzed by GC techniques shall have their identifications verified by an analyst competent in the interpretation of gas chromatograms. Two criteria must be satisfied to verify the identifications:

3.3.4.1 Elution of the sample component within the retention time window (established by the procedures in Exhibit E) of the standard component analyzed on the same GC column and instrument, as specified in Exhibit D, CLP, Organics.

3.3.4.2 Analysis of the sample and standard on a second GC column with a stationary phase with retention characteristics dissimilar to that used in 3.3.4.1 above, and meeting the same criteria for elution of the sample component and the standard as in 3.3.4.1 above.

3.4 Quantification of Compounds Verified in Section 3.3.

3.4.1 The Laboratory shall quantify components analyzed by GC/MS techniques and identified in Section 3.2 and verified in Section 3.3 by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall perform quantification utilizing the internal standards specified in Exhibit E, Part 2, Tables 2.1 or 2.2.

3.4.2 The Laboratory shall determine response factors for each 12-hour time period of GC/MS analysis and shall include a calibration check of the initial five-point calibration as described in Exhibit E.

3.4.3 The Laboratory shall quantify components analyzed by GC/EC techniques and identified in Section 3.2 and verified in Section 3.3 by the external standard method stipulated in Exhibit D, CLP, Organics.

3.4.4 The Laboratory shall perform an initial three-point calibration, verify its linearity, determine the breakdown of labile components, and determine calibration factors for all standards analyzed by GC/EC techniques as described in Exhibit D, CLP, Organics and Exhibit E.

3.5 Tentative Identification of Non-TCL Sample Components.

3.5.1 For each sample analyzed by GC/MS techniques, the Laboratory shall conduct mass spectral library searches to determine tentative compound identifications as follows. For each volatile fraction, the Laboratory shall conduct a search to determine the possible identity of the ten (10) organic compounds of greatest concentration which are not system monitoring compounds and are not listed in the CLP-TCL list in Exhibit C. For each semivolatile fraction, the Laboratory shall conduct a search to determine the possible identification of the (20) non-surrogate organic compounds of greatest concentration which are not listed in Exhibit C. In performing searches, the most recent release of the NIST/EPA/MSDC mass spectral library must be used.

***NOTE**: Substances with responses less than 10 percent of the nearest internal standard are not required to be searched in this fashion.*

3.5.2 Only after visual comparison of sample spectra with the spectra from the library searches will the mass spectral interpretation specialist assign a tentative identification. If the compound does not meet the identification criteria of Section 3.3, it shall be reported as unknown. The mass spectral specialist should give additional classification of the unknown compound, if possible (i.e., unknown aromatic, unknown hydrocarbon, unknown acid type, unknown chlorinated compound). If probable molecular weights can be distinguished, include them.

3.5.3 The Laboratory shall not report as tentatively identified compounds (TIC) any CLP-TCL compounds from volatile fraction (i.e., do not report late-eluting volatile compounds as TICs in the semivolatile analysis). However, The Laboratory may report pesticide target compounds that appear as semivolatile tentatively identified compounds.

3.6 Quality Assurance/Quality Control Procedures.

3.6.1 All specific quality assurance procedures prescribed in Exhibits D and E shall be strictly adhered to by the Laboratory. Records documenting the use of the Protocol shall be maintained in accordance with the document control procedures prescribed in Exhibit F, and shall be reported in accordance with Exhibit B, Reporting Requirements and Deliverables, and Exhibit H, Data Dictionary and Format for Data Deliverables in Computer-Readable Format.

3.6.2 The Laboratory shall establish a Quality Assurance Program Plan (QAPP) with the objective of providing sound analytical chemical measurements. This program shall incorporate the quality control procedures, any necessary corrective action, and all documentation required during data collection as well as the quality assessment measures performed by management to ensure acceptable data production.

3.6.3 The Laboratory shall perform one spiked sample analysis (matrix spike), one duplicate spiked sample analysis (matrix spike duplicate), and one spiked blank analysis (matrix spike blank) for each group of samples of a similar matrix (for water or soil samples) and concentration level (for volatile and semivolatile soil samples only) for the following, whichever is most frequent, unless otherwise specified in a Project Workplan:

- Each Case of field samples received, OR
- Each 20 samples in a Case, OR
- Each 7 calendar day period during which field samples in a Case were received (said period beginning with the receipt of the first sample in that Sample Delivery Group).

Matrix spikes and matrix spike duplicates shall be carried through the entire analytical process from extraction to final GC/MS or GC/EC analysis, including all Protocol Performance/Delivery Requirements.

3.6.4 The Laboratory shall prepare and analyze one laboratory reagent blank (method blank) for each group of samples of a similar matrix (for water or soil samples), extracted by a similar method (separatory funnel, continuous liquid-liquid extraction, or sonication, as specified in Exhibit D), and a similar concentration level (for volatile and semivolatile soil samples only) for the following, whichever is most frequent:

- Each Case of field samples received, OR
- Each 20 samples in a Case, including matrix spikes and reanalyses, OR
- Each 7 calendar day period during which field samples in a Case were received (said period beginning with the receipt of the first sample in that Sample Delivery Group), OR
- Whenever samples are extracted.

Volatile analysis requires one method blank for each 12-hour time period when volatile target compounds are analyzed.

Semivolatile and pesticide method blanks shall be carried through the entire analytical process from extraction to final GC/MS or GC/EC analysis, including all Protocol Performance/Delivery Requirements.

3.6.5 The Laboratory shall verify instrument performance for each 12-hour time period, to include the following: Decafluorotriphenylphosphine (DFTPP) and/or Bromofluorobenzene (BFB) as applicable, and a specific calibration using standards of defined concentration to monitor response, retention time, and mass spectra.

3.6.6 Additional quality control shall be conducted in the form of the analysis of laboratory evaluation samples submitted to the Laboratory by the NYSDEC. The results of all such control or laboratory evaluation samples may be used as grounds for termination of noncompliant Laboratories. "Compliant performance" is defined as that which yields correct compound identification and concentration values as determined by the NYSDEC, as well as meeting the contract requirements for analysis (Exhibit D), quality assurance/quality control (Exhibit E), data reporting and other deliverables (Exhibits B and H), and sample custody, sample documentation and SOP documentation (Exhibit F).

4.0 40 CFR Inorganics and Conventionals (Part 136)

4.1 In Exhibit D, 100, 200, 300, and 400 Series, NYSDEC provides the Laboratory with specific analytical procedures that may be used. Specific regulatory requirements that may limit the usage of these methods are provided in Section IV of this Exhibit A. These methods include instructions and references for sample preparation of samples containing low-to-medium concentrations of inorganics and organics for ICP analysis, flame, flameless and cold vapor AA analysis and classical wet-chemical analysis. The identification and quantification of elements shall be accomplished using either ICP or AA methods for metals whichever method will achieve the contract required quantitation limit (Exhibit C). Conventionals shall be analyzed by the individual procedures specified in Exhibit D.

4.2 The Laboratory shall establish and use on a continuing basis QA/QC procedures including the daily or (as required) more frequent use of standard reference solutions from USEPA or the National Institute of Standards and Technology (NIST), or secondary standards traceable thereto, where available at appropriate concentrations, i.e., standard solutions designed to insure that operating parameters of equipment and procedures, from sample collection through identification and quantification, produce reliable data. Exhibit E specifies the QA/QC procedures required. Additional quality assurance and quality control may be required on a semi-annual basis in the form of Performance Evaluation Samples submitted by NYSDEC for analysis and instrument verifications. (See Exhibit E)

4.3 For the purpose of this Protocol one analysis unit by ICP spectroscopy, flame, flameless, cold vapor AA and conventionals shall be considered the analysis of the appropriate blank samples, check samples and standards (with the frequency specified in Exhibit E) and the sample for one or more parameters listed in Exhibit C as specified by the Contract Lab Sample Information Sheet. A full sample analysis shall be considered one or more of the analysis units defined above. Duplicate sample, laboratory control sample, and matrix spiked sample analyses shall each be considered a separate and billable sample analysis.

4.4 Definition of a Sample - A sample consists of all components, perhaps more than one phase, contained inside appropriate receptacles. More than one container may be used for a single sample; individual containers may contain preservatives for different analysis portions. Containers may be glass or plastic.

4.5 The Laboratory shall adhere to chain-of-custody and document control procedures described in Exhibit G. Documentation as described therein shall be required to show that all procedures are being strictly followed. This documentation must be reported for each sample as specified in Exhibit B. The data must be reported in the exact format of the NYSDEC forms, specified in Exhibit B.

4.6 The Laboratory must designate and utilize key personnel meeting the minimum requirements, as specified in Section III of this Exhibit, and comply with all terms and conditions of the contract. NYSDEC reserves the right to review personnel qualifications and reject those not meeting the minimum experience requirements. Experience is defined as more than 50 percent of the personnel's productive work time in active participation of a given task.

5.0 40 CFR Inorganics and Conventionals (Parts 261, 264, 268, 270)

5.1 In Exhibit D, SW846, NYSDEC provides the Laboratory with specific analytical procedures to be used. Specific regulatory requirements that may limit the usage of these methods are provided in Section IV of this Exhibit A. These methods include instructions and references for sample preparation of samples containing low-to-medium concentrations of inorganics and organics for ICP analysis, flame, flameless and cold vapor AA analysis and classical wet-chemical analysis. The identification and quantification of elements shall be accomplished using either ICP or AA methods for metals whichever method will achieve the contract required quantitation limit (Exhibit C). Conventionals shall be analyzed by the individual procedures specified in Exhibit D.

5.2 The Laboratory shall establish and use on a continuing basis QA/QC procedures including the daily or (as required) more frequent use of standard reference solutions from USEPA or the National Bureau of Standards, or secondary standards traceable thereto, where available at appropriate concentrations, i.e., standard solutions designed to insure that operating parameters of equipment and procedures, from sample collection through identification and quantification, produce reliable data. Exhibit E specifies the QA/QC procedures required. Additional quality assurance and quality control may be required on a semi-annual basis in the form of Performance Evaluation Samples submitted by NYSDEC for analysis and instrument verifications. (See Exhibit E)

5.3 For the purpose of this protocol one analysis unit by ICP spectroscopy, flame, flameless, cold vapor AA and conventionals shall be considered the analysis of the appropriate blank samples, check samples and standards (with the frequency specified in Exhibit E) and the sample for one or more parameters listed in Exhibit C as specified by the Contract Lab Sample Information Sheet. A full sample analysis shall be considered one or more of the analysis units defined above. Duplicate sample, laboratory control sample, and matrix spiked sample analyses shall each be considered a separate and billable sample analysis.

5.4 Definition of a Sample - A sample consists of all components, perhaps more than one phase, contained inside appropriate receptacles. More than one container may be used for a single sample; individual containers may contain preservatives for different analysis portions. Containers may be glass or plastic.

5.5 The Laboratory shall adhere to chain-of-custody and document control procedures described in Exhibit G. Documentation as described therein shall be required to show that all procedures are being strictly followed. This documentation must be reported for each sample as specified in Exhibit B. The data must be reported in the exact format of the NYSDEC forms, specified in Exhibit B.

5.6 The Laboratory must designate and utilize key personnel meeting the minimum requirements, as specified in Section III of this Exhibit, and comply with all terms and conditions of the contract. NYSDEC reserves the right to review personnel qualifications and reject those not meeting the minimum experience requirements. Experience is defined as more than 50 percent of the personnel's productive work time in active participation of a given task.

6.0 40CFR Organics (Part 136)

The Laboratory shall use its analytical experience and equipment to perform qualitative and quantitative analyses of the organic chemical pollutants listed in Exhibit C. Preparation of the samples shall be done as described in Exhibit D, 600 and 1600 Series. The Laboratory shall follow the protocols established by the NYSDEC for sample preparation, analysis, storage and preservation, before and after the analysis (see Exhibit D).

During preparation, the Laboratory shall fortify all standards, samples, blanks, matrix spikes, and matrix spike duplicates with surrogate spiking compounds (listed in Exhibit E). Additionally, all sample semivolatile extracts and aliquots for volatile organics analysis shall be spiked with internal standard compounds (listed in Exhibit E) before injection or purging.

In Exhibit D, 600 and 1600 Series, NYSDEC provides the Laboratory with the specific analytical procedures to be used. Specific regulatory requirements that may limit the usage of these methods are provided in Section IV of this Exhibit A. These methods include instructions for sample preparation, gas chromatographic, thin layer chromatographic and high performance liquid chromatographic analysis, mass spectrometric identification and data evaluation. Specific ions used for searching the mass spectral data for each compound are included.

For each sample, the Laboratory shall perform the following:

6.1 Receive and Prepare Organic Samples.

6.1.1 Receive and handle samples under the chain-of-custody procedures described in Exhibit G.

6.1.2 Prepare samples as described in Exhibit D. VOA analyses shall be performed within **10 (TEN)** days of sample receipt. Sample extractions shall be started within **5 (FIVE)** days, and completed within **7 (SEVEN)** days of sample receipt. Sample extracts must be completely analyzed within 40 days of extraction. (**NOTE**: This does not preclude the Protocol requirement of a 30-day turnaround of analytical data.)

6.2 Extraction and Analysis for Identification of Specific Organic Compounds.

6.2.1 Extracts and diluted aliquots prepared in Section 6.1. shall be analyzed by GC and GC/MS techniques given in Exhibit D for the 40CFR organic substances referenced in Exhibit C as specified in the Contract Lab Sample Information Sheet.

6.2.2 The target compounds listed in Exhibit C, 40 CFR shall be identified as described in the methodologies given in Exhibit D. Automated computer programs may be used to facilitate the identification.

6.3 Qualitative Verification of the Compounds Identified in Section 6.2.

6.3.1 The compounds initially identified by GC/MS using methods 624, 625, 1624, or 1625 in Section 6.2 shall be verified by an analyst competent in the

interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. Two criteria must be satisfied to verify the identifications: (1) elution of the sample component at the same GC relative retention time as the standard component, and (2) correspondence of the sample component and standard component mass spectra. This procedure requires the use of multiple internal standards.

6.3.2 The compounds initially identified by GC or HPLC procedures in Section 6.2 shall be verified by an analyst competent in the interpretation of chromatograms generated by the method performed, by comparison of the sample chromatogram to the chromatogram of a standard of the suspected compound. GC verification must be accomplished by the elution of the sample component at the same GC relative retention time as the standard component on two dissimilar GC columns. The Laboratory may confirm analytes by GC/MS, however, verification of comparable MDLs must be provided in the data package.

6.3.3 For establishing correspondence of the GC relative retention time (RRT), the sample component RRT must compare within ±0.06 RRT units of the RRT of the standard component. For reference, the calibration standard must be run on the same 12-hour time period as the sample.

For comparison of standard and sample component mass spectra, mass spectra obtained on the Laboratory's GC/MS are required. Once obtained, these standard spectra may be used for identification purposes only if the Laboratory's GC/MS meets the DFTPP and BFB daily tuning requirements of Tables 1.1 and 1.2 in Exhibit E. The standard spectra used may be from a laboratory generated library or obtained from the calibration standard run used to obtain reference RRTs.

These requirements for qualitative verification by comparison of mass spectra are as follows:

6.3.3.1 All ions present in the standard mass spectrum at a relative intensity greater than 10 percent (most abundant ion in the spectrum equals 100 percent) must be present in the sample spectrum.

6.3.3.2 The relative intensities of ions specified in (1) must agree within plus or minus 20 percent between the standard and sample spectra.

6.3.3.3 Ions greater than 10 percent in the sample spectrum but not present in the standard spectrum must be considered and accounted for by the analyst making the comparison. When GC/MS computer data processing programs are used to obtain the sample component spectrum, both the processed and the raw spectra must be evaluated. In Section 6.3, the verification process should favor false positives.

6.4 Quantification of Compounds Verified in Section 6.3.

6.4.1 The Laboratory shall quantify components identified in Section 6.2 and verified in Section 6.3 by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall

perform quantitation utilizing the internal standards specified in Exhibit E, Part 2, Tables 2.1 or 2.2.

6.4.2 The Laboratory shall determine response factors for each 12-hour time period and shall include a calibration check of the initial five point calibration as described in Exhibit E.

6.5 Tentative Identification of Non-TCL Sample Components.

6.5.1 For each sample analyzed by GC/MS, the Laboratory shall execute library searches on substances not listed in the 40CFR Organics list in Exhibit C. A maximum of 10 substances of greatest apparent concentration not listed in the 40CFR organics list in Exhibit C for each volatile organic fraction, and a maximum of 20 substances of greatest apparent concentration not listed in Exhibit C for the combined base/ neutral/acid fraction shall be tentatively identified via a forward search of the most recent available NIST/EPA/MSDC mass spectral library. (Substances with responses less than 10 percent of the nearest internal standard are not required to be searched in this fashion.) Only after visual comparison of sample spectra with the spectra from the library searches will the mass spectral interpretation specialist assign a tentative identification. If the unknown does not meet the identification criteria of Section 6.3 it should be reported as unknown.

7.0 40CFR Organics (Parts 261, 264, 268, 270)

The Laboratory shall use its analytical experience and equipment to perform qualitative and quantitative analyses of the organic chemical pollutants listed in Exhibit C. Preparation of the samples shall be done as described in Exhibit D, SW846. The Laboratory shall follow the protocols established by the NYSDEC for sample preparation, analysis, storage and preservation before and after the analysis (see Exhibit D).

During preparation, the Laboratory shall fortify all standards, samples, blanks, matrix spikes, and matrix spike duplicates with surrogate spiking compounds (listed in Exhibit E). Additionally, all sample semivolatile extracts and aliquots for volatile organics analysis shall be spiked with internal standard compounds (listed in Exhibit E) before injection or purging.

In Exhibit D, SW846, the NYSDEC provides the Laboratory with the specific analytical procedures to be used. Specific regulatory requirements that may limit the usage of these methods are provided in Section IV of this Exhibit A. These methods include instructions for sample preparation, gas chromatographic, thin layer chromatographic and high performance liquid chromatographic analysis, mass spectrometric identification and data evaluation. Specific ions used for searching the mass spectral data for each compound are included.

For each sample, the Laboratory shall perform the following:

7.1 Receive and Prepare Organic Samples.

7.1.1 Receive and handle samples under the chain-of-custody procedures described in Exhibit G.

7.1.2 Prepare samples as described in Exhibit D. VOA analyses shall be performed within **10 (TEN)** days of sample receipt, regardless of sample matrix. Sample extractions shall be started within **5 (FIVE)** days, and completed within **7 (SEVEN)** days of sample receipt, regardless of sample matrix. Sample extracts must be completely analyzed within 40 days of extraction. (**NOTE**: This does not preclude the Protocol requirement of a 30-day turnaround of analytical data.)

7.2 Extraction and Analysis for Identification of Specific Organic Compounds.

7.2.1 Extracts and diluted aliquots prepared in Section 7.1. shall be analyzed by GC and GC/MS techniques given in Exhibit D for the 40 CFR organic substances referenced in Exhibit C as specified in the Contract Lab Sample Information Sheet.

7.2.2 The target compounds listed in Exhibit C, 40 CFR shall be identified as described in the methodologies given in Exhibit D. Automated computer programs may be used to facilitate the identification.

7.3 Qualitative Verification of the Compounds Identified in Section 7.2.

7.3.1 The compounds initially identified by GC/MS using methods 8240, 8260, 8250, or 8270 in Section 7.2 shall be verified by an analyst competent in the interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. Two criteria must be satisfied to verify the identifications: (1) elution of the sample component at the same GC relative retention time as the standard component, and (2) correspondence of the sample component and standard component mass spectra. This procedure requires the use of multiple internal standards.

7.3.2 The compounds initially identified by GC or HPLC procedures in Section 7.2 shall be verified by an analyst competent in the interpretation of chromatograms generated by the method performed, by comparison of the sample chromatogram to the chromatogram of a standard of the suspected compound. GC verification must be accomplished by the elution of the sample component at the same GC relative retention time as the standard component on two dissimilar GC columns. The Laboratory may confirm analytes by GC/MS, however, verification of comparable MDLs must be provided in the data package.

7.3.3 For establishing correspondence of the GC relative retention time (RRT), the sample component RRT must compare within ±0.06 RRT units of the RRT of the standard component. For reference, the calibration standard must be run on the same 12-hour time period as the sample.

For comparison of standard and sample component mass spectra, mass spectra obtained on the Laboratory's GC/MS are required. Once obtained, these standard spectra may be used for identification purposes only if the Laboratory's GC/MS meets the DFTPP and BFB daily tuning requirements of Tables 1.1 and 1.2 in Exhibit E. The standard spectra used may be from a laboratory-generated library or obtained from the calibration standard run used to obtain reference RRTs.

These requirements for qualitative verification by comparison of mass spectra are as follows:

7.3.3.1 All ions present in the standard mass spectrum at a relative intensity greater than 10 percent (most abundant ion in the spectrum equals 100 percent) must be present in the sample spectrum.

7.3.3.2 The relative intensities of ions specified in (1) must agree within plus or minus 20 percent between the standard and sample spectra.

7.3.3.3 Ions greater than 10 percent in the sample spectrum but not present in the standard spectrum must be considered and accounted for by the analyst making the comparison. When GC/MS computer data processing programs are used to obtain the sample component spectrum, both the processed and the raw spectra must be evaluated. In Section 7.3, the verification process should favor false positives.

7.4 Quantification of Compounds Verified in Section 7.3.

7.4.1 The Laboratory shall quantify components identified in Section 7.2 and verified in Section 7.3 by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall perform quantitation utilizing the internal standards specified in Exhibit E.

7.4.2 The Laboratory shall determine response factors for each 12-hour time period and shall include a calibration check of the initial five point calibration as described in Exhibit E.

7.5 Tentative Identification of Non-TCL Sample Components.

7.5.1 For each sample analyzed by GC/MS, the Laboratory shall execute library searches on substances not listed in the 40CFR Organics list in Exhibit C. A maximum of 10 substances of greatest apparent concentration not listed in the 40CFR organics list in Exhibit C for each volatile organic fraction, and a maximum of 20 substances of greatest apparent concentration not listed in Exhibit C for the combined base/ neutral/acid fraction shall be tentatively identified via a forward search of the most recent available NIST/EPA/MSDC mass spectral library. (Substances with responses less than 10 percent of the nearest internal standard are not required to be searched in this fashion.) Only after visual comparison of sample spectra with the spectra from the library searches will the mass spectral interpretation specialist assign a tentative identification. If the unknown does not meet the identification criteria of Section 7.3 it should be reported as unknown.

8.0 Organics (500 Series)

The Laboratory shall use its analytical experience and equipment to perform qualitative and quantitative analyses of the organic chemical pollutants listed in Exhibit C. Preparation of the samples shall be done as described in Exhibit D, 500 Series. The Laboratory shall follow the protocols established by the NYSDEC for sample preparation, analysis, reporting and deliverables, storage and preservation before and after the analysis (see Exhibit D).

During preparation, the Laboratory shall fortify all samples, standards, blanks, matrix spikes, and matrix spike duplicates with surrogate spiking compounds (listed in Exhibit E). Additionally, all sample semi-volatile extracts and aliquots for volatile organics analysis shall be spiked with internal standard compounds (listed in Exhibit E) before injection or purging.

In Exhibit D, 500 Series, the NYSDEC provides the Laboratory with the specific analytical procedures to be used. These methods include instructions for sample preparation, gas chromatographic, thin layer chromatographic and high performance liquid chromatographic analysis, mass spectrometric identification and data evaluation. Specific ions used for searching the mass spectral data for each compound are included.

For each sample, the Laboratory shall perform the following:

8.1 Receive and Prepare Organic Samples.

8.1.1 Receive and handle samples under the chain-of-custody procedures described in Exhibit G.

8.1.2 Prepare samples as described in Exhibit D. VOA analyses shall be performed within **10 (TEN)** days of sample receipt. Semivolatile extractions shall be started within **5 (FIVE)** days, and completed within **7 (SEVEN)** days of sample receipt. Sample extracts must be completely analyzed within 40 days of extraction. (**NOTE**: This does not preclude the Protocol requirement of a 30-day turnaround of analytical data.)

8.2 Extraction and Analysis for Identification of Specific Organic Compounds.

8.2.1 Extracts and diluted aliquots prepared in Section 8.1. shall be analyzed by GC and GC/MS techniques given in Exhibit D for the 40 CFR organic substances referenced in Exhibit C as specified in the Contract Lab Sample Information Sheet.

8.2.2 The target compounds listed in Exhibit C, 40 CFR shall be identified as described in the methodologies given in Exhibit D. Automated computer programs may be used to facilitate the identification.

8.3 Qualitative Verification of the Compounds Identified in Section 8.2.

8.3.1 The compounds initially identified by GC/MS in Section 8.2 shall be verified by an analyst competent in the interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. Two criteria must be satisfied to verify the identifications: (1) elution of the sample component at the same GC relative retention time as the standard component, and (2) correspondence of the sample component and standard component mass spectra. This procedure requires the use of multiple internal standards.

8.3.2 The compounds initially identified by GC or HPLC procedures in Section 8.2 shall be verified by an analyst competent in the interpretation of chromatograms generated by the method performed, by comparison of the sample

chromatogram to the chromatogram of a standard of the suspected compound. GC verification must be accomplished by the elution of the sample component at the same GC relative retention time as the standard component on two dissimilar GC columns. The Laboratory may confirm analytes by GC/MS, however, verification of comparable MDLs must be provided in the data package.

8.3.3 For establishing correspondence of the GC relative retention time (RRT), the sample component RRT must compare within ±0.06 RRT units of the RRT of the previous standard. The calibration standard must be run as indicated in the appropriate method.

For comparison of standard and sample component mass spectra, mass spectra obtained on the Laboratory's GC/MS are required. Once obtained, these standard spectra may be used for identification purposes only if the Laboratory's GC/MS meets the DFTPP and BFB daily tuning requirements of Tables 1.1 and 1.2 in Exhibit E. The standard spectra used may be from a laboratory generated library or obtained from the calibration standard run used to obtain reference RRTs.

These requirements for qualitative verification by comparison of mass spectra are as follows:

8.3.3.1 All ions present in the standard mass spectrum at a relative intensity greater than 10 percent (most abundant ion in the spectrum equals 100 percent) must be present in the sample spectrum.

8.3.3.2 The relative intensities of ions specified in (1) must agree within plus or minus 20 percent between the standard and sample spectra.

8.3.3.3 Ions greater than 10 percent in the sample spectrum but not present in the standard spectrum must be considered and accounted for by the analyst making the comparison. When GC/MS computer data processing programs are used to obtain the sample component spectrum, both the processed and the raw spectra must be evaluated. In Section 8.3, the verification process should favor false positives.

8.4 Quantification of Compounds Verified in Section 8.3.

8.4.1 The Laboratory shall quantify components identified in Section 8.2 and verified in Section 8.3 by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall perform quantitation utilizing the internal standards specified in Exhibit E, Part 2, Tables 2.1 or 2.2.

8.4.2 The Laboratory shall determine response factors at the method specified frequency and shall include a calibration check of the initial five point calibration as described in Exhibit E.

8.5 Tentative Identification of Non-TCL Sample Components.

8.5.1 For each sample analyzed by GC/MS, the Laboratory shall execute library searches on substances not listed in the 40 CFR Organics list in

Exhibit C. A maximum of 10 substances of greatest apparent concentration not listed in the 40 CFR organics list in Exhibit C for each volatile organic fraction, and a maximum of 20 substances of greatest apparent concentration not listed in Exhibit C for the combined base/ neutral/acid fraction shall be tentatively identified via a forward search of the most recent available NIST/EPA/MSDC mass spectral library. (Substances with responses less than 10 percent of the nearest internal standard are not required to be searched in this fashion.) Only after visual comparison of sample spectra with the spectra from the library searches will the mass spectral interpretation specialist assign a tentative identification. If the unknown does not meet the identification criteria of Section 8.3 it should be reported as unknown.

9.0 Non-Conventional Pesticides

The Laboratory shall use its analytical experience and equipment to perform qualitative and quantitative analyses of the organic chemical pollutants listed in Exhibit C. Preparation of the samples shall be done as described in Exhibit D, 600 and 1600 Series. The Laboratory shall follow the protocols established by the NYSDEC for sample preparation, analysis, storage and preservation before and after the analysis (see Exhibit D).

During preparation, the Laboratory shall fortify all samples, standards, blanks, matrix spikes, and matrix spike duplicates with surrogate spiking compounds (listed in Exhibit E). Additionally, all sample semi-volatile extracts and aliquots for volatile organics analysis shall be spiked with internal standard compounds (listed in Exhibit E) before injection or purging.

In Exhibit D, 600 and 1600, the NYSDEC provides the Laboratory with the specific analytical procedures to be used. Specific regulatory requirements that may limit the usage of these methods are provided in Section IV of this Exhibit A. These methods include instructions for sample preparation, gas chromatographic, thin layer chromatographic and high performance liquid chromatographic analysis, mass spectrometric identification and data evaluation. Specific ions used for searching the mass spectral data for each compound are included.

For each sample, the Laboratory shall perform the following:

9.1 Receive and Prepare Organic Samples.

9.1.1 Receive and handle samples under the chain-of-custody procedures described in Exhibit G.

9.1.2 Prepare samples as described in Exhibit D. Sample extractions shall be started within **5 (FIVE)** days and completed within **7 (SEVEN)** days of sample receipt. Sample extracts must be completely analyzed within 40 days of extraction. (**NOTE**: This does not preclude the protocol requirement of a 30-day turnaround of analytical data.)

9.2 Extraction and Analysis for Identification of Specific Organic Compounds.

9.2.1 Extracts and diluted aliquots prepared in Section 9.1. shall be analyzed by GC and GC/MS techniques given in Exhibit D for the 40 CFR organic

substances referenced in Exhibit C as specified in the Contract Lab Sample Information Sheet.

9.2.2 The target compounds listed in Exhibit C, shall be identified as described in the methodologies given in Exhibit D. Automated computer programs may be used to facilitate the identification.

9.3 Qualitative Verification of the Compounds Identified in Section 9.2.

9.3.1 The compounds initially identified by GC/MS in Section 9.2 shall be verified by an analyst competent in the interpretation of mass spectra by comparison of the suspect mass spectrum to the mass spectrum of a standard of the suspected compound. Two criteria must be satisfied to verify the identifications: (1) elution of the sample component at the same GC relative retention time as the standard component, and (2) correspondence of the sample component and standard component mass spectra. This procedure requires the use of multiple internal standards.

9.3.2 The compounds initially identified by GC or HPLC procedures in Section 9.2 shall be verified by an analyst competent in the interpretation of chromatograms generated by the method performed, by comparison of the sample chromatogram to the chromatogram of a standard of the suspected compound. GC verification must be accomplished by the elution of the sample component at the same GC relative retention time as the standard component on two dissimilar GC columns. The Laboratory may confirm analytes by GC/MS, however, verification of comparable MDLs must be provided in the data package.

9.3.3 For establishing correspondence of the GC relative retention time (RRT), the sample component RRT must compare within ±0.06 RRT units of the RRT of the standard component. For reference, the calibration standard must be run at the frequency specified in the method.

For comparison of standard and sample component mass spectra, mass spectra obtained on the Laboratory's GC/MS are required. Once obtained, these standard spectra may be used for identification purposes only if the Laboratory's GC/MS meets the DFTPP and BFB daily tuning requirements of Tables 1.1 and 1.2 in Exhibit E. The standard spectra used may be from a laboratory generated library or obtained from the calibration standard run used to obtain reference RRTs.

These requirements for qualitative verification by comparison of mass spectra are as follows:

9.3.3.1 All ions present in the standard mass spectrum at a relative intensity greater than 10 percent (most abundant ion in the spectrum equals 100 percent) must be present in the sample spectrum.

9.3.3.2 The relative intensities of ions specified in (1) must agree within plus or minus 20 percent between the standard and sample spectra.

9.3.3.3 Ions greater than 10 percent in the sample spectrum but not present in the standard spectrum must be considered and

accounted for by the analyst making the comparison. When GC/MS computer data processing programs are used to obtain the sample component spectrum, both the processed and the raw spectra must be evaluated. In Section 9.3, the verification process should favor false positives.

9.4 Quantification of Compounds Verified in Section 9.3.

9.4.1 The Laboratory shall quantify components identified in Section 9.2 and verified in Section 9.3 by the internal standard method stipulated in Exhibit D. Where multiple internal standards are required by NYSDEC, the Laboratory shall perform quantitation utilizing the internal standards specified in Exhibit E, Part 2, Tables 2.1 or 2.2.

9.4.2 The Laboratory shall determine response factors at the method specified frequency and shall include a calibration check of the initial five point calibration as described in Exhibit E.

9.5 Tentative Identification of Non-TCL Sample Components.

9.5.1 For each sample analyzed by GC/MS, the Laboratory shall execute library searches on substances not listed in the 40 CFR Organics list in Exhibit C. A maximum of 10 substances of greatest apparent concentration not listed in the 40 CFR organics list in Exhibit C for each volatile organic fraction, and a maximum of 20 substances of greatest apparent concentration not listed in Exhibit C for the combined base/ neutral/acid fraction shall be tentatively identified via a forward search of the most recent available NIST/EPA/MSDC mass spectral library. (Substances with responses less than 10 percent of the nearest internal standard are not required to be searched in this fashion.) Only after visual comparison of sample spectra with the spectra from the library searches will the mass spectral interpretation specialist assign a tentative identification. If the unknown does not meet the identification criteria of Section 9.3 it should be reported as unknown.

10.0 Quality Assurance/Quality Control Procedures

10.1 All specific quality assurance procedures prescribed (Exhibit E, QA/QC Requirements) shall be strictly adhered to by the Laboratory. Records documenting the use of the protocol shall be maintained in accordance with the document control procedures prescribed in Exhibit F, and reported in accordance with Exhibit B, "Reporting Requirements and Deliverables".

10.2 The Laboratory shall establish and use on a continuing basis QA/QC procedures including the daily or (as required) more frequent use of standard reference solutions from USEPA, the National Institute of Standards and Technology or secondary standards traceable thereto, where available at appropriate concentrations (i.e., standard solutions designed to ensure that operating parameters of equipment and procedures, from sample collection through identification and quantitation, produce reliable data). Exhibit E specifies the QA/QC procedures required.

10.3 The Laboratory shall perform one spiked sample analysis (matrix spike), one duplicate/spiked duplicate sample analysis (matrix duplicate/matrix spike duplicate),

and one matrix spike blank for each group of samples of a similar matrix (for water or soil samples) and concentration level (for soil samples only), once:

- each Sample Delivery Group (SDG) of field samples received, OR
- each 20 field samples in an SDG, OR
- each 7 calendar day period during which field samples in a SDG were received (said period beginning with the receipt of the first sample in that SDG),

OR AS DIRECTED BY THE BUREAU OF WATERSHED ASSESSMENT AND RESEARCH OR THE PROJECT OFFICER.

whichever is most frequent.

Specific samples to be spiked will be identified to the Laboratory by either BWAR or the Project Officer. Matrix spikes, matrix spike duplicates or matrix spike blank as required by the method shall be carried through the entire analytical process from extraction to final GC/MS or GC/EC analysis, including all Contract Performance/ Delivery Requirements (see Exhibit B and E).

10.4 The Laboratory shall prepare and analyze one laboratory reagent blank (method blank) for each group of samples of a similar matrix (for water or soil samples), extracted by a similar method (separatory funnel or continuous liquid-liquid extraction), and a similar concentration level (for soil samples only), once:

- each SDG of field samples received, OR
- each 20 field samples in a SDG, OR
- each 7 calendar day period during which field samples in a SDG were received (said period beginning with the receipt of the first sample in that SDG), OR
- whenever samples are extracted,

whichever is most frequent.

Volatile analysis requires one method blank for each 12-hour time period when volatile TCL compounds are analyzed.

Semivolatile and pesticide method blanks shall be carried through the entire analytical process from extraction to final GC/MS or GC/EC analysis, including all Contract Performance/Delivery Requirements (see Contract Schedule).

10.5 The Laboratory shall perform instrument calibration (by "hardware tune") at each method specified frequency, to include: decafluorotriphenyl-phosphine (DFTPP) and/or bromofluorobenzene (BFB) as applicable, and a specific calibration using standards of defined concentration to monitor response, retention time and mass spectra.

Additional quality control shall be conducted in the form of the analysis of Performance Evaluation check samples submitted to the Laboratory as authorized by NYSDEC. The results of comparison studies are due within 30 calendar days of receipt of the samples.

The results of all such control or PE check samples may be used as grounds for termination of noncompliant laboratories. "Compliant performance" is defined as that which yields correct compound identification and concentration values as determined by NYSDEC, as well as meeting the contract requirements for analysis (Exhibits C and D), quality assurance/quality control (Exhibit E), data reporting and other deliverables (Exhibits B and H), and sample custody, sample documentation and SOP documentation (Exhibit F).

10.6 After award of a contract and before the first sample results are due and on a semiannual basis thereafter, using standard reference materials, the Laboratory shall determine the analytical instrument detection limits (IDLs). The Laboratory should compare these instrumental detection limits with sample detection limits to determine if in-house quality control procedures are effective.

For inorganics the IDL is determined by multiplying by the Students t-Test value the standard deviation obtained for the analysis of a standard solution (each analyte in reagent water) at a concentration of 3x-5x the estimated IDL on three days with a minimum of seven measurements per day.

For organics the IDL is determined by multiplying by the Students t-Test value the standard deviation obtained for minimum of three replicate analyses of a standard solution at a concentration of 3x-5x the estimated IDL (each analyte in reagent water).

These analyses shall be performed using the instrumental conditions in Exhibit D on standards in solvent for base/neutrals, acids, and pesticides/PCBs and on standards diluted into reagent water for volatile organics and inorganics. The standard deviation (s_c) at this concentration is then calculated with n-1 degrees of freedom. The instrument detection limits shall be calculated as follows:

$$IDL = t_{n-1} \times s_c$$

where t_{n-1} is the Students t-Test value for a 99% confidence level at the n-1 level and n is the number of replicates. For three replicates, $t_{n-1} = 6.965$ and for twenty-one replicates, $t_{n-1} = 2.528$.

These values shall be supplied to the data users (see Exhibit B, "Reporting Requirements and Deliverables").

11.0 Reporting Requirements

NYSDEC has provided to the Laboratory formats for the reporting of data (Exhibits B and H). The Laboratory shall be responsible for completing and returning weekly reports, analysis data sheets and submitting computer-readable data on floppy diskette in the format specified in this Protocol and within the time specified in the Contract Performance/Delivery Schedule.

11.1 Use of formats other than those designated by NYSDEC will be deemed as noncompliance. Such data are unacceptable. Resubmission in the specified format at no additional cost to the government will be required. In addition the Laboratory may be subject to late reporting penalties.

11.2 Computer generated forms may be submitted in the hardcopy data package(s) provided that the forms are in EXACT NYSDEC FORMAT. This means that

the order of data elements is the same as on each NYSDEC required form, including form numbers and titles, page numbers and header information.

11.3 The data reported by the Laboratory on the hardcopy data forms and the associated computer-readable data submitted by the Laboratory must contain identical information. If during government inspection discrepancies are found, the Laboratory shall be required to resubmit either or both sets of data at no additional cost to the government within 10 days of the date of a written request to do so. All requests regarding clarifications, omissions, or transcription errors must be adequately addressed within the 10-day time period.

12.0 Laboratory Equipment Requirements

The Laboratory shall provide analytical equipment and technical expertise for this Protocol as specified below: The Laboratory shall maintain, at a minimum, all analytical equipment allocated for a contract or work plan under this Protocol.

12.1 Inductively coupled plasma (ICP) emission spectrometer with the capability to analyze metals sequentially or simultaneously and/or atomic absorption spectrometer (AA) equipped for flame analysis.

12.2 Atomic absorption (AA) spectrometer equipped with graphite furnace.

12.3 Atomic absorption spectrometer equipped for cold vapor AA (or a specific mercury analyzer) analysis capabilities.

12.4 Analytical equipment/apparatus for classical wet chemical analyses as described in Exhibit D.

12.5 Gas chromatograph(s) equipped with a purge and trap device and electrolytic conductivity and photoionization detectors for volatile organic analysis.

12.6 The Laboratory shall have sufficient gas chromatographs equipped with electron capture detectors and data systems to meet the pesticide/PCB analysis required by a contract or project work plan. The GC/EC/DS for Superfund-CLP pesticide analysis shall be equipped with wide bore capillary columns and a suitable detector and data system as described in Exhibit D, CLP, Organics.

12.7 The GC analyses performed under this protocol shall be performed using method specified columns and shall be equipped with detectors specified for those individual analyses as described in Exhibit D.

12.8 Gas chromatograph/mass spectrometer/data system (GC/ MS/DS) equipped with a purge and trap device for volatile organic analysis. A separate, dedicated instrument is required for the analysis of low concentration volatile organics by Methods 525.2 and Exhibit D, CLP, Organics.

The Laboratory's GC/MS instrument system for volatiles shall have the following:

12.8.1 The GC/MS shall be equipped with a glass jet separator when using packed columns.

12.8.2 The computer shall be interfaced by hardware to the mass spectrometer and be capable of acquiring continuous mass scans for the duration of the chromatographic program.

12.8.3 The computer shall be equipped with mass storage devices for saving all data from the GC/MS runs.

12.8.4 Computer software shall be available to allow searching GC/MS runs for specific ions and plotting the intensity of the ions with respect to time or scan number.

12.8.5 A computer data system must be interfaced to the mass spectrometer that allows the continuous acquisition and storage, on machine readable media, of all mass spectra obtained throughout the duration of the chromatographic program. The computer must have software that allows searching any GC/MS data file for ions of a specified mass and plotting such ion abundances versus time or scan number. This type of plot is defined as an Extracted Ion Current Profile (EICP). Software must also be available that allows integrating the abundance in any EICP between specified time or scan number limits. Also, for the non-target compounds, software must be available that allows for the comparison of sample spectra against reference library spectra. The most recent release of the NIST/EPA/MSDC mass spectral library shall be used as the reference library. The data system must be capable of flagging all data files that have been edited manually by laboratory personnel.

12.9 Gas chromatograph/mass spectrometer/data system (GC/MS/DS) for semi-volatile organic analysis.

The Laboratory's GC/MS instrument system for semi-volatiles shall have the following:

12.9.1 The computer shall be interfaced by hardware to the mass spectrometer and be capable of acquiring continuous mass scans for the duration of the chromatographic program.

12.9.2 The computer shall be equipped with mass storage devices for saving all data from the GC/MS runs.

12.9.3 Computer software shall be available to allow searching GC/MS runs for specific ions and plotting the intensity of the ions with respect to time or scan number.

12.9.4 The GC/MS shall be equipped with a split/splitless injector and GC to MS interface capable of extending a fused silica capillary column into the ion source. The column is to be 30 meters long by 0.25 or 0.32 mm inside diameter, bonded DB-5, fused silica or equivalent.

12.9.5 A computer data system must be interfaced to the mass spectrometer that allows the continuous acquisition and storage, on machine readable media, of all mass spectra obtained throughout the duration of the chromatographic program. The computer must have software that allows searching any GC/MS data file for ions of a specified mass and plotting such ion abundances versus time or scan number. This type of plot is defined as an

Extracted Ion Current Profile (EICP). Software must also be available that allows integrating the abundance in any EICP between specified time or scan number limits. Also, for the non-target compounds, software must be available that allows for the comparison of sample spectra against reference library spectra. The most recent release of the NIST/EPA/MSDC mass spectral library shall be used as the reference library. The data system must be capable of flagging all data files that have been edited manually by laboratory personnel.

12.10 The Laboratory shall provide adequate instrument redundancy, through multiple instruments and/or extensive in-house stocks of replacement parts and circuit boards, to ensure that at least one operating instrument of each type necessary may reasonably be expected to be available at any one time. The Laboratory shall maintain, at the minimum, all analytical equipment allocated for this Protocol at the time of the on-site audit.

12.11 The Laboratory shall use a magnetic tape storage device capable of recording data suitable for long-term off-line storage. The Laboratory shall retain all raw GC/MS data acquired during the entire contract or project period on magnetic tape in appropriate instrument manufacturer format. The Laboratory is required to retain these tapes, with associated hardcopy tape logbook identifying tape contents (see Exhibit E) for a period of three (3) years from the end of the contract or project. The Laboratory shall provide the magnetic tapes to the NYSDEC within seven (7) days of request by the BWAR or the Project Officer.

12.12 The Laboratory shall have a computerized MS library search system capable of providing a forward comparison, utilizing the standard spectra contained in the mass spectral library. The most recent release of the NIST/EPA/MSDC mass spectral library must be used.

12.12.1 The system shall provide a numerical ranking of the standard spectra most closely corresponding to the sample spectra examined.

12.12.2 The data system shall remove background signals from suspect chemical pollutant spectra.

12.13 The Laboratory shall have in-house (at the laboratory facility) and operable, a device capable of analyzing purgeable organics as described in Exhibit D.

12.14 The Laboratory shall have, in-house, the appropriate standards for <u>all</u> target compounds listed in Exhibit C, which are specified in a contract or project work plan, prior to accepting any samples under this Protocol.

12.15 The Laboratory shall have an IBM or IBM-compatible minicomputer or PC capable of recording required sample data on 1.44 M-Byte 3.5 inch diskettes, in ASCII text file format and in accordance with the file, record and field specifications listed in Exhibit H.

13.0 Laboratory Personnel

The minimum functional requirements necessary to meet the terms and conditions of this Protocol are listed in items 13.1 - 13.18 below. The Laboratory shall designate and utilize qualified key personnel to perform these functions. A single individual may not

serve in more than two of the following supervisory positions, except for the Quality Assurance/Quality Control Officer position, which must be held by someone with no other responsibilities.

13.1 Laboratory Supervisor

13.2 Project Manager

13.3 Quality Assurance/Quality Control Officer

13.4 ICP Spectroscopist

13.5 ICP Operator

13.6 Flameless Atomic Absorption (AA) Spectroscopist

13.7 Flame and Cold Vapor Atomic Absorption Spectroscopist

13.8 Inorganic Sample Preparation Specialist

13.9 Classical Wet Chemical Techniques Analyst

13.10 Inorganic Chemist (Backup)

13.11 GC/MS Laboratory Supervisor

13.12 GC/MS/DS Operator

13.13 Systems Manager

13.14 Programmer Analyst

13.15 Mass spectral interpretation specialist

13.16 GC Laboratory Supervisor

13.17 Pesticide Residue Analysis Expert for organochlorine pesticides and PCBs

13.18 Purge and Trap Volatile Organics Analysis Expert

13.19 Sample Preparation Laboratory Supervisor

13.20 Sample Extraction/Concentration Specialist

13.21 Sample Custodian responsible for sample receipt, storage, and tracking, including chain-of-custody procedures.

13.22 Data Reporting and Delivery Officer

Additional Requirements

14.0 Information Requests

The Laboratory shall respond within seven days to written requests from data recipients for additional information or explanations that result from NYSDEC inspection activities unless otherwise specified in the contract or project work plan.

15.0 Unused Samples and Extracts

The Laboratory is required to retain unused sample volume and used sample containers for a period of 120 days after data submission. From time of receipt until disposal, the Laboratory shall maintain all samples and unused sample volumes stored at 4°C (±2°C), protected from light. Samples and unused sample volumes must be stored separately from sample extracts and standards.

The Laboratory shall preserve all sample extracts after analysis in bottles/vials with Teflon-lined septa and shall maintain stored extracts at 4°C (±2°C). The Laboratory is required to retain the sample extracts for 180 days after data submission. During that time, the Laboratory shall submit the extracts within 7 days after request, by the Project Officer or the Bureau of Watershed Assessment and Research as specified in Exhibit B.

16.0 Chain-of-Custody/Document Control Procedures

The Laboratory shall adhere to chain-of-custody and document control procedures described in Exhibit F. Documentation, as described therein, shall be required to show that all procedures are being strictly followed. This documentation shall be reported as the Complete SDG File Purge (see Exhibit B).

17.0 Sample Scheduling

Sample shipments to the Laboratory's facility will be scheduled by DEC Project Officers and coordinated by the Bureau of Watershed Assessment and Research (BWAR) acting on behalf of the Project Officer. The Laboratory shall communicate with BWAR personnel by telephone as necessary throughout the process of sample scheduling, shipment, analysis and data reporting, to ensure that samples are properly processed.

If there are problems with the samples (e.g., mixed media, containers broken or leaking) or sample documentation/paperwork (e.g., Contract Lab Sample Information Sheet not with shipment, sample bottle and Sample Information Sheet numbers do not correspond) the Laboratory shall immediately contact BWAR for resolution. The Laboratory shall immediately notify BWAR regarding any problems and laboratory conditions that affect the timeliness of analyses and data reporting. In particular, the Laboratory shall notify BWaR personnel, or the Project Officer in advance regarding sample data that will be delivered late and shall specify the estimated delivery date.

18.0 Sample Delivery Groups

Sample analyses will be scheduled by groups of samples, each defined as a Sample Delivery Group (SDG) and identified by a unique NYSDEC SDG number assigned by the Project Officer. An SDG signifies a group of samples collected at one site or geographical areas over a finite time period, and will include one or more field samples with associated blanks. Samples may be shipped to the Laboratory in a single shipment

or multiple shipments over a period of time, up to 7 days, depending on the size of the SDG.

A Sample Delivery Group (SDG) is defined by the following, whichever is most frequent, unless otherwise specified in a Project Workplan:

- all field samples received with the same SDG #, OR
- each 20 field samples within an SDG, OR
- each 7 day calendar period during which field samples in an SDG are received (said period beginning with the receipt of the first sample in the SDG).

All data (hardcopy and computer-readable format) for all samples in a Sample Delivery Group are due concurrently to all data recipients 30 days after receipt of the last sample received in the Sample Delivery Group. Data for all samples in a Sample Delivery Group must be submitted together (in one package) in the order specified in Exhibit B. The Sample Delivery Group number is identified on the Contract Lab Sample Information Sheet. The SDG number must be reported on all data reporting forms.

The SDG Receipt Date is the day the last sample in the SDG is received. Data for all samples in the SDG are due 30 days following this date.

The Laboratory is responsible for identifying each Sample Delivery Group as samples are received, through proper sample documentation (see Exhibit B) and communication with BWAR personnel.

19.0 Contract Lab Sample Information Sheets

Each sample received by the Laboratory will be labeled with a DEC sample number, and accompanied by a Contract Lab Sample Information Sheet form bearing the Case number, SDG number, sample number and descriptive information regarding the sample and a chain-of-custody sheet. The Laboratory shall complete and sign the chain-of-custody sheet, recording the date of sample receipt and sample condition on receipt for each sample container.

The Laboratory shall submit signed copies of Contract Lab Sample Information Sheets and the chain-of-custody forms for all samples in a Sample Delivery Group with the analytical report for that SDG. These sheets shall be submitted in Sample Delivery Group sets (i.e., all sheets for a Sample Delivery Group shall be clipped together) with an SDG Cover Sheet containing information regarding the Sample Delivery Group, as specified in Exhibit B.

20.0 Weekly Sample Submission Summary

The Laboratory shall submit, via e-mail, a Weekly Sample Submission Summary no later than the Wednesday following the week being reported. This information must be transmitted electronically as a Microsoft Excel compatible file. NYSDEC will provide the file structure.

21.0 Identifying Numbers

NYSDEC Case numbers, SDG numbers, and DEC sample numbers shall be used by the Laboratory in identifying samples received under this Protocol both verbally and in reports/correspondence.

22.0 Sample Shipments

Samples will routinely be shipped to the Laboratory through an overnight delivery service. However, as necessary, the Laboratory shall be responsible for any handling or processing required for the receipt of sample shipments, including pick-up of samples at the nearest servicing airport, bus station or other carrier service within the Laboratory's geographical area. The Laboratory shall be available to receive sample shipments at any time the delivery service is operating, including Saturdays.

23.0 Acceptance of Samples

The Laboratory shall accept all samples scheduled by DEC, provided that the total value of samples received in any calendar month does not exceed the monthly limitation expressed in the contract. Should the Laboratory elect to accept additional samples, the Laboratory shall remain bound by all contract requirements for analysis of those samples accepted.

Section III - Detailed Technical And Management Requirements

As cited in Section II, the Laboratory shall have the following technical and management capabilities.

***NOTE**: For those technical functions which require a minimum educational degree and experience, an advanced degree in chemistry or any scientific/engineering discipline, (e.g., Master's or Doctorate) does not substitute for the minimum experience requirements.*

Any personnel changes affecting the key personnel as stated in Exhibit A, Section III, Items 1 and 2, the Laboratory shall notify in writing the Bureau of Watershed Assessment and Research (BWAR) within 14 days of the personnel change. The Laboratory shall provide a detailed resume to BWAR for the replacement personnel within 14 days of the Laboratory's assignment of the personnel. The resume shall include position description of titles, education (pertinent to this Protocol), number of years of experience (pertinent to this Protocol) month and year hired, previous experience and publications.

1.0 Technical Functions

1.1 Quality Assurance Officer

1.1.1 Responsible for overseeing the quality assurance aspects of the data and reporting directly to upper management to meet all terms and conditions of this Protocol.

1.1.2 Qualifications:

1.1.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.1.2.2 Experience:

Minimum of five years of environmental laboratory experience, including at least one year of applied experience with QA principles and practices in an analytical laboratory.

1.2 GC/MS Laboratory Supervisor

1.2.1 Responsible for all technical efforts of the GC/MS laboratory to meet all terms and conditions of this Protocol.

1.2.2 Qualifications:

1.2.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.2.2.2 Experience:

Minimum of three years of laboratory experience in operating a GC/MS, including at least one year of supervisory experience.

1.3 GC/MS Operator Qualifications

1.3.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.3.2 Experience:

One year of experience in operating and maintaining GC/MS/DS in conjunction with the educational requirement; or, in lieu of the educational requirement, three additional years of experience in operating and maintaining GC/MS/DS and interpreting GC/MS data.

1.4 Mass Spectral Interpretation Specialist Qualifications

1.4.1 Education:

1.4.1.1 Minimum of Bachelor's degree in chemistry or any physical science.

1.4.1.2 Training course(s) in mass spectral interpretation.

1.4.2 Experience:

Minimum of two years of experience in mass spectral interpretation.

1.5 GC Laboratory Supervisor

1.5.1 Responsible for all technical efforts of the GC Laboratory to meet all terms and conditions of this Protocol.

1.5.2 Qualifications:

1.5.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.5.2.2 Experience:

Minimum of three years of laboratory experience in operating a GC/EC, including at least one year of supervisory experience.

1.6 GC Operator

1.6.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.6.2 Experience:

One year of experience in operating and maintaining GC/EC in conjunction with the educational requirement; or, in lieu of the educational requirement, three additional years of experience in operating and maintaining GC/EC and interpreting GC/EC data.

1.7 Pesticide Residue Analysis Expert Qualifications

1.7.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.7.2 Experience:

Minimum of two years in operating and maintaining GC and interpreting GC chromatograms.

1.8 Organic Sample Preparation Laboratory Supervisor

1.8.1 Responsible for all technical efforts of sample preparation for organic analysis to meet all terms and conditions of the Protocol.

1.8.2 Qualifications:

1.8.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.8.2.2 Experience:

Minimum of three years of laboratory experience in organic sample preparation, including at least one year of supervisory experience.

1.9 Organic Extraction/Concentration Expert Qualifications

1.9.1 Education:

Minimum of high school diploma and a college level course in general chemistry or equivalent.

1.9.2 Experience:

Minimum of one year experience in extraction/concentration.

1.10 Organic Analysis Technical Staff Redundancy

The Laboratory shall have a minimum of one (1) chemist available at any one time as a back-up technical person with the following qualifications, to ensure continuous operations to accomplish the required work as specified by this Protocol.

1.10.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.10.2 Experience:

Minimum of one year experience in each of the following areas:

1.10.2.1 GC/MS operation and maintenance for volatiles and semivolatiles analyses.

1.10.2.2 Mass spectral interpretation.

1.10.2.3 Extraction

1.10.2.4 Pesticide/Aroclor analysis.

1.11 Inorganics Laboratory Supervisor

1.11.1 Responsible for all technical efforts of the Inorganics Laboratory to meet all terms and conditions of this Protocol.

1.11.2 Qualifications:

1.11.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.11.2.2 Experience:

Minimum of three years of laboratory experience, including at least one year in a supervisory position.

1.12 ICP Spectroscopist Qualifications

1.12.1 Education:

1.12.1.1 Minimum of Bachelor's degree in chemistry or any physical science.

1.12.1.2 Specialized training in ICP Spectroscopy.

1.12.2 Experience:

Minimum of two years of applied experience with ICP analysis of environmental samples.

1.13 ICP Operator Qualifications

1.13.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.13.2 Experience:

Minimum of one year of experience in operating and maintaining ICP instrumentation, in conjunction with the educational requirement; or, in lieu of the educational requirement, three additional years of experience in operating and maintaining ICP instrumentation.

1.14 Atomic Absorption (AA) Operator Qualifications

1.14.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.14.2 Experience:

Minimum of one year of experience in operating and maintaining AA instrumentation for each of the following AA techniques: (a) flame (if flame will be used), (b) graphite furnace, and (c) cold vapor, in conjunction with the educational requirement; or, in lieu of the educational requirement, three additional years of experience in operating and maintaining AA instrumentation, including flame, graphite furnace, and cold vapor techniques.

1.15 Metals/Wet-Chemistry Sample Preparation Laboratory Supervisor

1.15.1 Responsible for all technical efforts of metals and wet-chemical sample preparations to meet all terms and conditions of this Protocol.

1.15.2 Qualifications:

1.15.2.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.15.2.2 Experience:

Minimum of three years of laboratory experience, including at least one year of supervisory experience.

1.16 Inorganic Sample Preparation Specialist Qualifications

1.16.1 Education:

Minimum of high school diploma and a college level course in general chemistry or equivalent.

1.16.2 Experience:

Minimum of six months of experience in an analytical laboratory.

1.17 Classical Techniques (Wet-Chemical) Analyst Qualifications

1.17.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.17.2 Experience:

Minimum of six months of experience with classical chemistry laboratory procedures, in conjunction with the educational requirements; or, in lieu of the educational requirement, two years of additional equivalent experience.

1.18 System Manager

1.18.1 Responsible for the management and quality control of all computing systems (hardware, software, documentation and procedures), generating, updating, and quality controlling automated deliverables to meet all terms and conditions of this Protocol.

1.18.2 Qualifications:

1.18.2.1 Education:

Minimum of Bachelor's degree with four or more intermediate courses in programming, information management, database management systems, or systems requirements analysis.

1.18.2.2 Experience:

Minimum of three years experience in data or systems management or programming including one year of experience with the software being utilized for data management and generation of laboratory reports.

1.19 Programmer Analyst

1.19.1 Responsible for the installation, operation and maintenance of software and programs generating, updating, and quality controlling analytical databases and automated deliverables to meet all terms and conditions of this Protocol.

1.19.2 Qualifications:

1.19.2.1 Education:

Minimum of Bachelor's degree with four or more intermediate courses in programming, information management, database management systems, or systems requirements analysis.

1.19.2.2 Experience:

Minimum of three years experience in systems or applications programming including one year of experience with the software being utilized for data management and generation of laboratory reports.

1.20 Inorganic Technical Staff Redundancy

In order to ensure continuous operations to accomplish the required work as specified under this Protocol, the Laboratory shall have a minimum of one (1) chemist available at all times as a back-up technical person with the following qualifications:

1.20.1 Education:

Minimum of Bachelor's degree in chemistry or any physical science.

1.20.2 Experience:

Minimum of one year of experience in each of the following areas:

1.20.2.1 ICP operation and maintenance.

1.20.2.2 AA operation and maintenance.

1.20.2.3 Classical chemistry analytical procedures.

1.20.2.4 Sample preparation for metals/wet-chemical analysis.

1.21 Sample Custodian

1.21.1 Education:

Minimum of high school diploma or equivalency diploma.

1.21.2 Experience:

One year of general laboratory experience.

2.0 Facilities

The adequacy of the facilities and equipment is of equal importance as the technical staff to accomplish the required work as specified by this Protocol.

2.1 Sample Receipt Area

Adequate, contamination-free, well-ventilated work space provided with chemical resistant bench top and fume hood for receipt and safe handling of NYSDEC samples.

2.2 Secure Storage Area

Sufficient locked refrigerator space to maintain unused NYSDEC sample volume for 90 days after data submission and sample extracts for 90 days after data submission. Samples must be stored in an atmosphere demonstrated to be free from all potential contaminants. **NOTE**: Volatile samples must be stored in a refrigerator used only for storage of volatile samples submitted under this Protocol. Samples, sample extracts, and standards must be stored separately to prevent cross contamination. Semivolatile and pesticide/Aroclor standards and extracts must be stored separately from volatile standards and extracts. Inorganic samples and digestates must be stored securely and separately from organic samples. Area access must be restricted to sample custodians.

2.3 Sample Preparation Area

The sample preparation area shall be separate and isolated from the volatile analysis area. It shall have adequate, contamination-free, well-ventilated work space provided with:

2.3.1 Benches with chemical resistant tops and exhaust hoods. **NOTE**: Standards must be prepared in a glove box or isolated area.

2.3.2 Source of distilled or demineralized organic-free water.

2.3.3 Analytical balance(s) located away from draft and rapid change in temperature.

3.0 Instrumentation

At a minimum, the Laboratory shall have the instruments listed in Table 1.1 operative at the time of the on-site laboratory audit and committed for the full duration of any project to be performed under this Protocol.

4.0 Data Management and Handling

4.1 Hardware - Laboratory shall have an IBM or IBM-compatible mini-computer or PC capable of recording required sample data on 3.5 inch double-sided, double-density 1.44 M-byte diskettes in ASCII text file format and in accordance with the file, record and field specifications listed in Protocol, Exhibit H.

Other minimum requirements include:

- Hard disk of at least 20 M-bytes.
- Asynchronous, Hayes-compatible modem capable of at least 2,400 baud transmission speed. In addition, MNP level 5 compatibility is recommended.
- Modem capable of at least 2,400 baud transmission speed which is compatible with the EPA Telecommunications Network.

Table 1.1

Fraction	No. of Instruments	Type of Instrument
Volatiles	2	GC/MS/DS with purge and trap device
Low Concentration Volatiles	1	Dedicated GC/MS/DS with purge and trap device
Volatiles	2	GC/HECD/PID with dual column
Semivolatiles (BNA)	2	GC/MS/DS
Pesticides/Aroclors	2	GC/EC with dual column
ICP Metals	2	EITHER ICP Emission Spectrophotometer AND/OR Flame Atomic Absorption Spectrophotometer
Graphite Furnace AA Metals	2	Atomic Absorption Spectrophotometer with Graphite Furnace Atomizer or Axial ICP or ICP-MS or any redundant combination
Mercury	2	Mercury Cold Vapor AA Analyzer or AA Instrument modified for Cold Vapor Analysis

4.2 Software - Software, utilized in generating, updating and quality controlling analytical databases and automated deliverables shall have the following additional capabilities:

- Editing and updating databases.

- QC of automated deliverables.

- Controlled access using user ID and file password protection.

4.3 The Laboratory shall also be able to submit reports and data packages as specified in Exhibit B of this Protocol. To complete this task, the Laboratory shall be required to provide space, tables and adequate copy machines to meet the Protocol requirements.

5.0 Laboratory Management Capability

The Laboratory must have an organization with well-defined responsibilities for each individual in the management system to ensure sufficient resources for the NYSDEC contract or project(s) and to maintain a successful operation. To establish this capability, the Laboratory shall designate personnel to carry out the following responsibilities for the NYSDEC contract or project(s). Functions include, but are not limited to, the following:

5.1 Technical Staff

Responsible for all technical efforts for the NYSDEC contract or project(s). The Laboratory shall have adequate number of technical personnel to meet the requirements of this Protocol.

5.2 Project Manager

Responsible for overall aspects of NYSDEC contract or project(s) (from sample receipt through data delivery) and shall be the primary contact for the Bureau of Watershed Assessment and Research or Project Officers.

5.3 Sample Custodian

Responsible for receiving the NYSDEC samples (logging, handling and storage).

5.4 Quality Assurance Officer

Responsible for overseeing the quality assurance aspects of the data and reporting directly to upper management.

5.5 Document Control Officer

Responsible for all aspects of data deliverables: organization, packaging, copying, and delivery. Responsible for ensuring that all documents generated are placed in the Complete SDG File for inventory and are delivered to the appropriate NYSDEC Regional personnel or other receiver.

Section IV -- NYSDEC Data Package Summary Forms 62

Section I -- Contract Reports/Deliverables Distribution

The following table details the Protocol reporting deliverables requirements and specifies the distribution that is required for each deliverable.

***NOTE**: Specific recipient names and addresses are subject to change during the term of the contract. The Bureau of Watershed Assessment and Research (BWAR) will notify the Laboratory in writing of such changes when they occur.*

Item		No. of Copies	Delivery Schedule	Distribution (1)	(2)	(3)
A.	Standard Operating Procedures	1	60 days after notification of contract award, and as required in Exhibit E.	X		
B.	Quality Assurance Plan	1	60 days after notification of contract award, and as required in Exhibit E.	X		
C.	Weekly Sample Receipt Summary	1	Wednesday following the week covered by the report	X		
*D.	Sample Data Summary Package	2	30 days after receipt of last sample in Sample Delivery Group (SDG)**		X	X
*E.	Sample Data Package	2	30 days after receipt of last sample in SDG		X	X
*F.	Data in Computer-Readable Form	1	30 days after receipt of last sample in SDG	X		
G.	GC/MS Tapes	Lot	Retain for 365 days after data submission, or submit within 7 days after receipt of written request by BWAR	As Directed		

Item		No. of Copies	Delivery Schedule	Distribution (1) (2) (3)
H.	Extracts	Lot	Retain for 90 days after data submission or submit within 7 days after receipt of written request by BWAR	As Directed
*I.	Complete SDG File Purge	1 Pkg	30 days after receipt of last sample in Sample Delivery Group	X
J.	Semiannual Verification of Instrument Parameters	1	Semiannually: 15th day of January, July	X

* Concurrent delivery required. Delivery shall be made such that all designated recipients receive the item on the same calendar day.

** Sample Delivery Group (SDG) is a group of samples within a Case, received over a period of 7 days or less and not exceeding 20 samples. Data for all samples in the SDG are due concurrently, unless specified otherwise in a project workplan. (See Exhibit A, for further description).

***NOTE**: As specified in the Protocol unless otherwise instructed by the BWAR the Laboratory shall dispose of unused sample volume and used sample bottles/containers no earlier than ninety (90) days following submission of analytical data.*

Distribution Addresses:

(1) Analytical Services Section
Bureau of Program Services and Research
NYS Department of Environmental Conservation
50 Wolf Road, Room 392
Albany, New York 12233-3502

(2) NYSDEC Sample Submitters

(3) NYSDEC Project Officers

The BWAR acting on behalf of the Project Officer, will provide the Laboratory with the list of addressees for the nine NYSDEC Regions. BWAR will provide the Laboratory with updated Regional address/name lists as necessary throughout the period of the contract and identify other client recipients on a case-by-case basis.

Section II -- Report Descriptions and Order of Data Deliverables

The Laboratory shall provide reports and other deliverables as specified in Section I. The required content and form of each deliverable is described in this Exhibit.

All reports and documentation MUST BE as follows:

- Legible,
- Clearly labeled and completed in accordance with instructions in this Exhibit,
- Arranged in the order specified in this Section, and
- Paginated consecutively in ascending order starting from the SDG Narrative.

If submitted documentation does not conform to the above criteria, the Laboratory will be required to resubmit such documentation with deficiency(ies) corrected, at no cost to NYSDEC.

Whenever the Laboratory is required to submit or resubmit data as a result of an on-site laboratory evaluation or through a Bureau of Watershed Assessment and Research (BWAR) action, or through a Project Directors request, the data must be clearly marked as ADDITIONAL DATA and sent to all Protocol specified data recipients. A cover letter shall be included which describes what data is being delivered, to which NYSDEC sample(s) it pertains, and who requested the data.

Sections IV and VI of this Exhibit contain copies of the required data reporting forms in Agency-specified formats, along with instructions to assist the Laboratory in accurately providing NYSDEC all required data. Data elements with field parameters for reporting data in computer readable form are contained in Exhibit H.

Descriptions of the requirements for each deliverable item cited in Section I, Contract Reports/Deliverables Distribution Schedule are specified in parts A-G of this Section. Items submitted concurrently MUST BE arranged in the order listed. Additionally, the components of each item MUST BE arranged in the order presented in this Section when the item is submitted.

Examples of specific data deliverables not included herein may be obtained by submitting a written request to the Bureau of Watershed Assessment and Research, stating the information requested, and signed by the Laboratory Manager.

A. - Standard Operating Procedures

See Exhibits E and F for requirements

B. - Quality Assurance Plan

See Exhibits E and F for requirements

C. - Weekly Sample Receipt Summary

Weekly Sample Receipt Summaries shall be submitted by the Wednesday following the week for which they are submitted. This information must be transmitted electronically as a Microsoft Excel compatible file. NYSDEC will provide the file structure.

The Weekly Sample Receipt Summary shall contain the following items:

- Lab name
- Contract number
- NYSDEC Case #
- NYSDEC SDG #
- NYSDEC Sample ID #
- Lab ID #
- Name of NYSDEC Sample Submitter
- Code numbers for requested analyses from Contract Laboratory Sample Information Sheet
- Sample Analysis Price - full sample price from contract for each sample # reported.
- List of NYSDEC sample numbers of all samples in the SDG, identifying the first and last samples received, and their dates of receipt.

***NOTE**: When more than one sample is received in the first or last SDG shipment, the "first" sample received would be the lowest sample number (considering both alpha and numeric designations); the "last" sample received would be the highest sample number (considering both alpha and numeric designations).*

The NYSDEC SDG# is found on the Contract Laboratory Sample Information Sheet. (The SDG number is also reported on all data reporting forms. See Section III, Forms Instruction Guide.)

D. - Sample Data Summary Package

As specified in the Delivery Schedule, one Sample Data Summary Package each shall be delivered to BWAR and the sample collector concurrently with delivery of other required sample data. The Sample Data Summary Package consists of copies of specified items from the Sample Data Package. These items are listed below and described under part C, Sample Data Package.

The Sample Data Summary Package shall be ordered as follows and shall be submitted separately (i.e., separated by rubber bands, clips or other means) directly preceding the Sample Data Package. Sample data forms shall be arranged in increasing NYSDEC sample number order, considering both letters and numbers. E400 is a lower sample number than RH100, as E precedes R in the alphabet.

The Sample Data Summary Package shall contain all data for all samples within one Sample Delivery Group of the Case as follows:

1. NYSDEC Data Package Summary Forms
2. SDG Narrative

3. By fraction (VOA, SV, PEST, INORG, CONV) and by sample within each fraction - tabulated target compound results (Form I-ORG or Form I-IN) and tentatively identified compounds (Form I-ORG, TIC) (VOA and BNA only)

4. By fraction (VOA, SV, and PEST) - surrogate spike analysis results (Form II-ORG) by matrix (water and/or soil) and for soil, by concentration (low or medium)

5. By fraction (VOA, SV, and PEST) - matrix spike/matrix spike duplicate/matrix spike blank results (Form III-ORG) - as required by method.

6. By fraction (VOA, SV, and PEST) - QC Check Sample/Standard Recovery Summary - If required by method.

7. By fraction (INORG and CONV only) - duplicate sample results (Form VI-IN)

8. By fraction (INORG and CONV only) - spike sample results (Form V-IN)

9. By fraction (VOA, SV, PEST, INORG, CONV) - blank data (Form IV-ORG and Form III-IN) and tabulated results (Form I-ORG and Form I-IN) including tentatively identified compounds (Form I-ORG, TIC)(VOA and BNA only).

10. By fraction (VOA and SV only) - internal standard area data (Form VIII-ORG).

E. - Sample Data Package

The Sample Data Package is divided into the eight major units described below. The last six units are each specific to an analytical fraction (volatiles, semivolatiles, pesticides/Aroclors, GC organics, inorganics, and conventional wet-chemistry). If the analysis of a fraction is not required, then that fraction-specific unit is not required as a deliverable.

The Sample Data Package shall include data for analyses of all samples in one Sample Delivery Group, including field samples, reanalyses, blanks, duplicates, spikes, matrix spikes, matrix spike duplicates, and matrix spike blanks.

All data produced in support of Superfund investigations/remediations as identified by checked boxes under the Contract Laboratory Section of the Contract Laboratory Sample Information Sheet (See Exhibit A)shall be reported as specified for the Superfund Category (paragraph 1.). All data generated in support of the SPDES program as identified by a CASE # beginning with the letter "E" shall be reported using ASP Category-B (paragraph 3.). All other samples shall be reported using either ASP Category A or ASP Category B described in paragraphs 2. and 3. The specific reporting level to be used shall be specified by the Contract Laboratory Sample Information Sheet, unless otherwise specified in a project workplan.

The Laboratory shall retain a copy of the Sample Data Package for 365 days after final acceptance of data. After this time, the Laboratory may dispose of the package.

1.0 Superfund Category

1.1 SDG Narrative

This document shall be clearly labeled "SDG Narrative" and shall contain: Laboratory name; Case number; Sample Delivery Group number (SDG); sample numbers in the SDG, differentiating between initial analyses and re-analyses; Contract number; and detailed documentation of any quality control, sample, shipment and/or analytical problems encountered in processing the samples reported in the data package.

Whenever data from sample re-analysis are submitted, the Laboratory shall state in the SDG Narrative for each re-analysis, whether it considers the re-analysis to be billable, and if so, why.

The Laboratory must also include any problems encountered: both technical and administrative, corrective actions taken, and resolution and an explanation for all flagged edits (i.e., manual edits) on quantitation lists.

The SDG Narrative shall contain the following statement, verbatim: "I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package and in the computer-readable data submitted on floppy diskette has been authorized by the Laboratory Manager or his designee, as verified by the following signature." This statement shall be directly followed by signature of the Laboratory Manager or his designee with a typed line below it containing the signer's name and title, and the date of signature.

Additionally, the SDG Narrative itself must be signed in original signature by the Laboratory Manager or his designee and dated.

1.2 Contract Lab Sample Information Sheets

A copy of the Contract Lab Sample Information Sheets (CLSIS) for all of the samples in the SDG. The CLSIS shall be arranged in increasing NYSDEC sample number order, considering both letters and numbering in ordering samples.

1.3 Chain-of-Custody Forms

Copies of both the external and internal chain-of-custody sheets for all samples within the SDG.

1.4 Superfund-CLP Volatiles Data

1.4.1 QC Summary

1.4.1.1 System Monitoring Compound Summary (Form II-CLP-VOA)

1.4.1.2 Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank Summary (Form III-CLP-VOA)

1.4.1.3 Method Blank Summary (Form IV-CLP-VOA)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank, by instrument.)

1.4.1.4 GC/MS Instrument Performance Check (Form V-CLP-VOA).

BFB in chronological order; by instrument.

1.4.1.5 Internal Standard Area and RT Summary (Form VIII-CLP-VOA)

In chronological order; by instrument.

1.4.1.6 Instrument Detection Limits

1.4.2 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I-CLP-VOA, including Form I-CLP-VOA-TIC), followed by the raw data for volatile samples. These sample packets should then be placed in increasing NYSDEC sample number order, considering both letters and numbers in ordering samples.

1.4.2.1 Target Compound Results - Organic Analysis Data Sheet (Form I-CLP-VOA).

Tabulated results (identification and quantitation) of the specified Superfund-CLP target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (reference C.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-CLP-VOA, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

1.4.2.2 Tentatively Identified Compounds (Form I-CLP-VOA-TIC).

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-CLP-VOA-TIC is the tabulated list of the highest probable match for up to 10 organic compounds not system monitoring compounds and are not listed in Exhibit C (Superfund-TCL) for the appropriate program under which the samples were submitted, including the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentrations. For estimating concentration, assume a response factor of 1, and estimate

the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent, i.e., use peak height for all comparisons or use total area count for all comparisons.*

1.4.2.3 Reconstructed Total Ion Chromatograms (RIC) for each sample or sample extract.

RICs must be normalized to the largest non-solvent component and contain the following header information:

- NYSDEC sample number
- Date and time of analysis
- GC/MS instrument ID
- Lab file ID

Internal standard and system monitoring compounds are to be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak.

If automated system procedures are used for preliminary identification and/or quantification of the Superfund Target Compound List (Superfund-TCL) compounds, the complete data system report must be included in all sample data packages in addition to the reconstructed ion chromatogram. The complete data system report shall include all of the information listed below. For laboratories which do not use the automated data system procedures, a laboratory "raw data sheet", which contains the following information, must be included in the sample data package in addition to the chromatogram.

- NYSDEC sample number
- Date and time of analysis
- RT or scan number of identified Superfund-TCL compounds
- Ion used for quantitation with measured area
- Copy of area table from data system
- GC/MS instrument ID
- Lab file ID

In all instances where the data system report has been edited, or where manual integration or quantitation has been performed, the GC/MS operator must identify such edits or manual procedures by initialing and dating the changes made to the report.

1.4.2.4 For each sample, by each compound identified, the following shall be included in the data package:

1.4.2.4.1 Copies of raw spectra and copies of background-subtracted mass spectra of target compounds listed in Exhibit C (Superfund-TCL) that are identified in the sample and corresponding background-subtracted TCL standard mass spectra. Spectra must be labeled with NYSDEC sample number, lab file ID, date and time of analysis, and GC/MS instrument ID; compound names must be clearly marked on all spectra.

1.4.2.4.2 Copies of mass spectra of organic compounds not listed in Exhibit C (Superfund-TCL) (Tentatively Identified Compounds), with associated best-match spectra (three best matches), labeled as in 1.4.2.4.1 above.

1.4.3 Standards Data

1.4.3.1 Initial Calibration Data (Form IV-CLP-VOA) - in order by instrument if more than one instrument used.

1.4.3.1.1 VOA standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for the initial (five point) calibration, labeled as in 1.4.2.3 above. Spectra are not required.

1.4.3.1.2 All initial calibration data that pertain to samples in the data package must be included, regardless of when it was performed and for which case. When more than one initial calibration is performed, the data must be put in chronological order, by instrument.

1.4.3.2 Continuing Calibration (Form VII-CLP-VOA) - in order by instrument, if more than one instrument used.

1.4.3.2.1 VOA standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for all continuing (12 hour) calibrations, labeled as in 1.4.2.3. Spectra are not required.

1.4.3.2.2 When more than one continuing calibration is performed, forms must be in chronological order, within fraction and instrument.

1.4.4 Raw QC Data

1.4.4.1 BFB (for each 12-hour period, for each GC/MS system utilized)

1.4.4.1.1 Bar graph spectrum, labeled as in 1.4.2.3.

1.4.4.1.2 Mass listing, labeled as in 1.4.2.3.

1.4.4.1.3 Reconstructed total ion chromatogram (RIC), labeled as in 1.4.2.3.

1.4.4.2 Blank Data - in chronological order.

***NOTE**: This order is different from that used for samples.*

1.4.4.2.1 Tabulated results (Form I-CLP-VOA)

1.4.4.2.2 Tentatively Identified Compounds (Form I-CLP-VOA-TIC) - even if none found.

1.4.4.2.3 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.4.2.3.

1.4.4.2.4 Superfund-TCL spectra with lab generated standard, labeled as in 1.4.2.4. Data systems which are incapable of dual display shall provide spectra in the following order:

- Raw Superfund-TCL compound spectra
- Enhanced or background subtracted spectra
- Laboratory generated Superfund-TCL standard spectra

1.4.4.2.5 GC/MS library search spectra for Tentatively Identified Compounds (TIC), labeled as in 1.4.2.4.

1.4.4.2.6 Quantitation/Calculation of Tentatively Identified Compound(s) (TIC) concentrations

1.4.4.3 Matrix Spike Blank Data

1.4.4.3.1 Tabulated results (Form I-CLP-VOA) of all Superfund-TCL compounds. Form I-CLP-VOA-TIC is required.

1.4.4.3.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.4.2.4. Spectra are required.

1.4.4.4 Matrix Spike Data

1.4.4.4.1 Tabulated results (Form I-CLP-VOA) of all Superfund-TCL compounds. Form I-CLP-VOA-TIC is <u>not</u> required.

1.4.4.4.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.4.2.4. Spectra are <u>not</u> required.

1.4.4.5. Matrix Spike Duplicate Data

1.4.4.5.1 Tabulated results (Form I-CLP-VOA) of all Superfund-TCL Compounds. Form I-CLP-VOA-TIC is <u>not</u> required.

1.4.4.5.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.3.2.4. Spectra are not required.

1.4.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

1.4.6 Copy of Extraction Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

1.5 Superfund-CLP Semivolatiles Data

1.5.1 QC summary

1.5.1.1 Surrogate Percent Recovery Summary (Form II-CLP-SV)

1.5.1.2 Matrix Spike/Matrix Spike Duplicate Summary (Form III-CLP-SV)

1.5.1.3 Method Blank Summary (Form IV-CLP-SV)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank.)

1.5.1.4 GC/MS Instrument Performance Check (Form V-CLP-SV).

DFTPP in chronological order; by instrument.

1.5.1.5 Internal Standard Area and RT Summary (Form VIII-CLP-SV).

1.5.1.6 Instrument Detection Limits.

1.5.2 Sample Data.

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I-CLP-SV, including Form I SV-TIC), followed by the raw data for semivolatile samples. These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

1.5.2.1 TCL Results - Organic Analysis Data Sheet (Form I-CLP-SV-1, SV-2).

Tabulated results (identification and quantitation) of the specified Superfund-CLP target compounds (Exhibit C). The validation and release

of these results is authorized by a specific, signed statement in the SDG Narrative (reference C.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-CLP-SV-1,-SV-2, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

1.5.2.2 Tentatively Identified Compounds (Form I-CLP-SV-TIC)

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-CLP-SV-TIC is the tabulated list of the highest probable match for up to 20 of the nonsurrogate organic compounds not listed in Exhibit C (Superfund-TCL). It includes the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentration. For estimating concentration, assume a response factor of 1, and estimate the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent, i.e., use peak height for all comparisons <u>or</u> use total area count for all comparisons.*

1.5.2.3 Reconstructed total ion chromatograms (RIC) for each sample, sample extract, standard, blank, and spiked sample.

RICs must be normalized to the largest nonsolvent component, and must contain the following header information:

- NYSDEC sample number
- Date and time of analysis
- GC/MS instrument ID
- Lab file ID

Internal standard and surrogate spiking compounds are to be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak.

If automated data system procedures are used for preliminary identification and/or quantification of the Superfund Target Compound List (Superfund-TCL) compounds, the complete data system report must be included in all sample data packages, in addition to the reconstructed ion chromatogram. The complete data system report shall include all of the information listed below. For laboratories which do not use the automated data system procedures, a laboratory "raw data sheet," containing the following

information, must be included in the sample data package in addition to the chromatogram.

- NYSDEC sample number
- Date and time of analysis
- RT or scan number of identified Superfund-TCL compounds
- Ion used for quantitation with measured area
- Copy of area table from data system
- GC/MS instrument ID
- Lab file ID

In all instances where the data system report has been edited, or where manual integration or quantitation has been performed, the GC/MS operator must identify such edits or manual procedures by initialing and dating the changes made to the report.

1.5.2.4 For each sample, by each compound identified, the following shall be included in the data package:

1.5.2.4.1 Copies of raw spectra and copies of background-subtracted mass spectra of target compounds listed in Exhibit C (Superfund-TCL) that are identified in the sample and corresponding background-subtracted Superfund-TCL standard mass spectra. Spectra must be labeled with NYSDEC sample number, lab file ID, date and time of analysis, and GC/MS instrument ID; compound names must be clearly marked on all spectra.

1.5.2.4.2 Copies of mass spectra of nonsurrogate organic compounds not listed in Exhibit C (Superfund-TCL) (Tentatively Identified Compounds) with associated best-match spectra (three best matches), labeled as in 1.5.2.4.1.

1.5.2.4.3 GPC chromatograms (if GPC performed).

1.5.3 Standards Data

1.5.3.1 Initial Calibration Data (Form VI-CLP-SV-1, SV-2) - in order by instrument, if more than one instrument used.

1.5.3.1.1 Semivolatile standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for the initial (five point) calibration, labeled in 1.5.2.3. Spectra are not required.

1.5.3.1.2 All initial calibration data that pertain to samples in the data package must be included, regardless of when it was performed and for which SDG. When more than one initial

calibration is performed, the data must be put in chronological order, by instrument.

1.5.3.2 Continuing calibration (Form VII-CLP-SV-1, SV-2) - in order by instrument, if more than one instrument used.

1.5.3.2.1 Semivolatile standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for all continuing (12 hour) calibrations, labeled as in 1.5.2.3. Spectra are not required.

1.5.3.2.2 When more than one continuing calibration is performed, forms must be in chronological order, by instrument.

1.5.3.3 Semivolatile GPC Calibration Data - UV detector traces showing peaks that correspond to the compounds in the semivolatile GPC calibration mixture. Traces must be labeled with GPC column identifier, date of calibration, and with compound names labeled either directly out from the peak, or on a printout of retention times, if retention times are printed over the peak. Do not include Form IX Pest-2, as the compounds used on that form are not appropriate for semivolatile sample extracts.

1.5.4 Raw QC Data

1.5.4.1 DFTPP (for each 12-hour period, for each GC/MS system utilized)

1.5.4.1.1 Bar graph spectrum, labeled as in 1.5.2.3.

1.5.4.1.2 Mass listing, labeled as in 1.5.2.3.

1.5.4.1.3 Reconstructed total ion chromatogram (RIC), labeled as in 1.5.2.3.

1.5.4.2 Blank Data - in chronological order by extraction date.

NOTE: *This order is different from that used for samples.*

1.5.4.2.1 Tabulated results (Form I-CLP-SV-1, SV-2)

1.5.4.2.2 Tentatively Identified Compounds (Form I-CLP-SV-TIC) - even if none found.

1.5.4.2.3 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.5.2.3.

1.5.4.2.4 Superfund-TCL spectra with lab generated standard, labeled as in 1.4.2.4. Data systems which are incapable of dual display shall provide spectra in order:

- Raw Superfund-TCL compound spectra
- Enhanced or background subtracted spectra

- Laboratory generated Superfund-TCL standard spectra

1.5.4.2.5 GC/MS library search spectra for Tentatively Identified Compounds (TIC), labeled as in 1.5.2.4.

1.5.4.2.6 Quantitation/Calculation of Tentatively Identified Compound(s) (TIC) concentrations

1.5.4.3 Matrix Spike Blank Data

1.5.4.3.1 Tabulated results (Form I-CLP-SV-1, SV-2) of all Superfund-TCL compounds. Form I-CLP-SV-TIC not required.

1.5.4.3.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.5.2.3. Spectra are required.

1.5.4.4 Matrix Spike Data

1.5.4.4.1 Tabulated results (Form I-CLP-SV-1, SV-2) of all Superfund-TCL compounds. Form I-CLP-SV-TIC not required.

1.5.4.4.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.5.2.3. Spectra are not required.

1.5.4.5 Matrix Spike Duplicate Data

1.5.4.5.1 Tabulated results (Form I-CLP-SV-1, SV-2) of all Superfund-TCL compounds. Form I-CLP-SV-TIC not required.

1.5.4.5.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 1.5.2.3. Spectra are not required.

1.5.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

1.5.6 Copy of Extraction Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

1.6 Superfund-CLP Pesticide/Aroclor Data

1.6.1 QC Summary

1.6.1.1 Surrogate Percent Recovery Summary (Form II-CLP-PEST)

1.6.1.2 Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank Summary (Form III-CLP-PEST)

1.6.1.3 Method Blank Summary (Form IV-CLP-PEST)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank.)

1.6.1.4 Instrument Detection Limits

1.6.2 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I-CLP-PEST), followed by the raw data for pesticide samples. These sample packets should then be placed in increasing NYSDEC sample number order, considering both letters and numbers in ordering samples.

1.6.2.1 Superfund-TCL Results - Organic Analysis Data Sheet (Form I-CLP-PEST).

Tabulated results (identification and quantitation) of the specified Superfund target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (reference E.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-CLP-PEST, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable. **NOTE**: Report analytical results to two significant figures for all pesticide/Aroclor samples.

1.6.2.2 Copies of pesticide chromatograms.

All chromatograms must be labeled with the following information.

- NYSDEC sample number.
- Volume injected (µL).
- Date and time of injection.
- GC column identification (by stationary phase and internal diameter).
- GC instrument identification.

- Positively identified compounds must be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak.

1.6.2.3 Copies of pesticide chromatograms from second GC column confirmation. Chromatograms to be labeled as in 1.6.2.2 above.

1.6.2.4 GC integration report or data system printout.

1.6.2.5 Manual work sheets.

1.6.2.6 If pesticide/Aroclors are confirmed by GC/MS, the Laboratory shall submit copies of reconstructed ion chromatograms, raw spectra and copies of background-subtracted mass spectra of Superfund target compounds listed in Exhibit C (Superfund-TCL) that are identified in the sample and corresponding background-subtracted Superfund-TCL standard mass spectra. Compound names must be clearly marked on all spectra. For multicomponent pesticides/Aroclors confirmed by GC/MS, the Laboratory shall submit mass spectra of 3 major peaks of multicomponent compounds from samples and standards.

1.6.3 Standards Data

1.6.3.1 Initial Calibration of Single Component Analytes (Form VI-CLP-PEST-1 and PEST-2) - all GC columns, all instruments, in chronological order by GC column and instrument.

1.6.3.2 Initial Calibration of Multicomponent Analytes (Form VI-CLP-PEST-3) - all GC columns, all instruments, in chronological order by GC column and instrument

1.6.3.3 Analyte Resolution Summary (Form VI CLP-PEST-4) - all GC columns and instruments, in chronological order by GC column and instrument.

1.6.3.4 Calibration Verification Summary (Form VII CLP-PEST-1) - for all Performance Evaluation Mixtures and Instrument blanks, on all GC columns and instruments, in chronological order by GC column and instrument.

1.6.3.5 Calibration Verification Summary (Form VII CLP-PEST-2) - for all mid point concentrations of Individual Standard Mixtures A and B and Instrument blanks used for calibration verification, on all GC columns and instruments, in chronological order by GC column and instrument.

1.6.3.6 Analytical Sequence (Form VIII CLP-PEST) - all GC columns and instruments, in chronological order by GC column and instrument.

1.6.3.7 Florisil Cartridge Check (Form IX CLP-PEST-1) - for all lots of cartridges used to process samples in the SDG.

1.6.3.8 Pesticide GPC Calibration (Form IX CLP-PEST-2) - all GPC columns, in chronological order by calibration date.

1.6.3.9 Pesticide Identification Summary for Single Component Analytes (Form X CLP-PEST-1) - for all samples with positively identified single component analytes, in order by increasing NYSDEC sample number.

1.6.3.10 Pesticide Identification Summary for Multicomponent Analytes (Form X CLP-PEST-2) - for all samples with positively identified multicomponent analytes, in order by increasing NYSDEC sample number.

1.6.3.11 Chromatograms and data system printouts are required for all standards including the following:

- Resolution Check Mixture.
- Performance Evaluation Mixtures, all.
- Individual Standard Mixture A, at three concentrations, each initial calibration.
- Individual Standard Mixture B, at three concentrations, each initial calibration.
- All multicomponent analytes (Toxaphene and Aroclors), each initial calibration.
- All mid point concentrations of Individual Standard Mixtures A and B used for calibration verification.
- Florisil cartridge check solution, all lots.
- Pesticide GPC Calibration Check Solution, all calibrations relating to samples in the SDG.
- All multicomponent analyte standards analyzed for confirmation.

1.6.3.12 A printout of retention times and corresponding peak areas or peak heights must accompany each chromatogram. In addition, all chromatograms are required to be labeled with the following:

- NYSDEC Sample Number for the standard, i.e., INDA1, INDA2, etc. (See Forms Instructions for details).
- Label all standard peaks for all individual compounds either directly out from the peak or on the printout of retention times if retention times are printed over the peak.
- Total nanograms injected for each standard.
- Date and time of injection.
- GC column identification (by stationary phase and internal diameter).
- GC instrument identification.

1.6.3.13 Pesticide GPC Calibration Data - UV detector traces showing peaks that correspond to the compounds in the pesticide GPC calibration mixture. Traces must be labeled with GPC column identifier, date of calibration, and with compound names labeled either directly out from the peak, or on a printout of retention times, if retention times are printed over the peak.

1.6.4 Raw QC Data

1.6.4.1 Blank Data - in chronological order, by type of blank (method, instrument, sulfur cleanup).

***NOTE**: This order is different from that used for samples.*

1.6.4.1.1 Tabulated results (Form I-CLP-PEST).

1.6.4.1.2 Chromatogram(s) and data system printout(s) (GC) for each GC column and instrument used for analysis, labeled as in 1.6.2.2 above.

1.6.4.2 Matrix Spike Data

1.6.4.2.1 Tabulated results (Form I-CLP-PEST) of all Superfund-TCL compounds.

1.6.4.2.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 1.6.2.2 above.

1.6.4.3 Matrix Spike Duplicate Data

1.6.4.3.1 Tabulated results (Form I-CLP-PEST) of all Superfund-TCL compounds.

1.6.4.3.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 1.6.2.2 above.

1.6.4.4 Matrix Spike Blank Data

1.6.4.4.1 Tabulated results (Form I-CLP-PEST) of all Superfund-TCL compounds.

1.6.4.4.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 1.6.2.2 above.

1.6.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

1.6.6 Copy of Extraction Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix

spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

1.7 Inorganic Data

Sample data shall be submitted with the Inorganic Analysis Data Reporting Forms for all samples in the SDG, arranged in increasing alphanumeric DEC sample number order, followed by the QC analyses data, Quarterly Verification of Instrument Parameters forms, raw data, and copies of the digestion and distillation logs.

1.7.1 Results -- Inorganic Analysis Data Sheet (FORM I-CLP-IN)

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I-CLP-IN. The quantitative values shall be reported in units of micrograms per liter (µg/L) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. No other units are acceptable. Results for solid sample must be reported on a dry weight basis. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

1.7.2 Quality Control Data

1.7.2.1 Initial and Continuing Calibration Verification [FORM II-CLP-IN (Part 1)]

1.7.2.2 CRDL Standard for AA and Linear Range Analysis for ICP [FORM II-CLP-IN (PART 2)]

1.7.2.3 Blanks [FORM III-CLP-IN]

1.7.2.4 ICP Interference Check Sample [FORM IV-CLP-IN]

1.7.2.5 Spike Sample Recovery [FORM V-CLP-IN (PART 1)]

1.7.2.6 Post Digest Spike Sample Recovery [FORM V-CLP-IN (PART 2)]

1.7.2.7 Duplicates [FORM VI-CLP-IN]

1.7.2.8 Laboratory Control Sample [FORM VII-CLP-IN]

1.7.2.9 Standard Addition Results [FORM VIII-CLP-IN]

1.7.2.10 ICP Serial Dilutions [FORM IX-CLP-IN]

1.7.2.11 Holding Times [FORM X-CLP-IN]

1.7.3 Verification of Instrument Parameters

1.7.3.1 Instrument Detection Limits (Quarterly) [FORM XI-CLP-IN]

1.7.3.2 ICP Interelement Correction Factors (Annually) [FORM XII-CLP-IN (PART 1)]

1.7.3.3 ICP Interelement Correction Factors (Annually) [FORM XII-CLP-IN (PART 2)]

1.7.3.4 ICP Linear Ranges (Quarterly) [FORM XIII-CLP-IN]

(Note that copies of Verification of Instrument Parameters forms for the current quarter must be submitted with each data package.)

1.7.4 Raw Data

For each reported value, the Laboratory shall include in the data package all raw data from the instrument used to obtain that value. This applies to all required QA/QC measurements, instrument standardization, as well as sample results. This statement does not apply to the Verifications of Instrument Parameters submitted as part of each data package. Raw data must contain all instrument readouts used for the sample results, including those readouts that may fall below the IDL. All AA and ICP instruments must provide a legible hard copy of the direct real-time instrument readout (i.e., stripcharts, printer tapes, etc.). A photocopy of the direct sequential instrument readout must be included. A hardcopy of the instrument's direct instrument readout for cyanide must be included if the instrumentation has the capability.

The order of raw data in the data package shall be: ICP, Flame AA, Furnace AA, Mercury, and Cyanide. All raw data shall include intensities (ICP) and absorbances with concentration units for flame AA, furnace AA, Mercury and Cyanide. All flame and furnace AA data shall be grouped by element.

Raw data must be labeled with DEC sample number and appropriate codes, shown in Table 1 following to unequivocally identify:

1.7.4.1 Calibration standards, including source and prep date.

1.7.4.2 Initial and continuing calibration blanks and preparation blanks.

1.7.4.3 Initial and continuing calibration verification standards, interference check samples, ICP serial dilution samples, CRDL Standard for ICP and AA, Laboratory Control Sample and Post Digestion Spike.

1.7.4.4 Diluted and undiluted samples (by DEC sample number) and all weights, dilutions and volumes used to obtain the reported values. (If the volumes, weights and dilutions are consistent for all samples in a given SDG, a general statement outlining these parameters is sufficient).

1.7.4.5 Duplicates.

1.7.4.6 Spikes (indicating standard solutions used, final spike concentrations, volumes involved). If spike information (source,

concentration, volume) is consistent for a given SDG, a general statement outlining these parameters is sufficient.

1.7.4.7 Instrument used, any instrument adjustments, data corrections or other apparent anomalies on the measurement record, including all data voided or data not used to obtain reported values and a brief written explanation.

1.7.4.8 All information for furnace analysis clearly and sequentially identified on the raw data, including DEC sample number, sample and analytical spike data, percent recovery, coefficient of variation, full MSA data, MSA correlation coefficient, full MSA data, MSA correlation coefficient, slope and intercepts of linear fit, final sample concentration (standard addition concentration), and type of background correction used: BS for Smith-Heiftje, BD for deuterium Arc, or BZ for Zeeman.

1.7.4.9 Time and date of each analysis. Instrument run logs can be submitted if they contain this information. If the instrument does not automatically provide times of analysis, these must be manually entered on all raw data for initial and continuing calibration verification and blanks, as well as interference check samples and linear range analysis.

1.7.4.10 Integration times for AA analyses.

1.7.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the instrument output report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

1.7.6 Digestion Logs

Logs shall be submitted in the following order: digestion logs for ICP, flame AA, furnace AA and mercury preparations, followed by a copy of the distillation log for cyanide. These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. laboratory control sample, preparation blank) correspond to each batch digested, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) indication of pH <2 or >12, as applicable.

2.0 ASP Category A

2.1 SDG Narrative

This document shall be clearly labeled "SDG Narrative" and shall contain: Laboratory name; SDG number; Sample Delivery Group number (SDG); sample numbers in the SDG, differentiating between initial analyses and re-analyses; Contract number; and detailed documentation of any quality control, sample, shipment and/or analytical problems encountered in processing the samples reported in the data package.

Whenever data from sample re-analysis are submitted, the Laboratory shall state in the SDG Narrative for <u>each</u> re-analysis, whether it considers the re-analysis to be billable, and if so, why.

The Laboratory must also include any problems encountered: both technical and administrative, corrective actions taken, and resolution and explanation for all flagged edits (i.e., manual edits) on quantitation lists.

The SDG Narrative shall contain the following statement, verbatim: "I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package and in the computer-readable data submitted on floppy diskette has been authorized by the Laboratory Manager or his designee, as verified by the following signature." This statement shall be directly followed by signature of the Laboratory Manager or his designee with a typed line below it containing the signer's name and title, and the date of signature.

Additionally, the SDG Narrative itself must be signed in original signature by the Laboratory Manager or his designee and dated.

2.2 Contract Lab Sample Information Sheets

A copy of the Contract Lab Sample Information Sheets (CLSIS) for all of the samples in the SDG. The CLSIS shall be arranged in increasing DEC sample number order, considering both letters and numbering in ordering samples.

2.3 NYSDEC Data Package Summary Forms

2.4 Chain-of-Custody Forms

Copies of both the external and internal chain-of-custody sheets for all samples within the SDG.

2.5 GC/MS Volatiles Data

2.5.1 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet. These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

2.5.1.1 TCL Results - Organic Analysis Data Sheet.

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (reference C.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

2.5.1.2 Tentatively Identified Compounds (Form 1-TIC).

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-TIC is the tabulated list of the highest probable match for up to 10 of the non-surrogate organic compounds not listed in Exhibit C for the appropriate program under which the samples were submitted, including the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentrations. For estimating concentration, assume a response factor of 1, and estimate the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent, i.e., use peak height for all comparisons or use total area count for all comparisons.*

2.6 GC/MS Semivolatiles Data

2.6.1 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I, including Form I-TIC). These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

2.6.1.1 TCL Results - Organic Analysis Data Sheet (Form I-SV-1, SV-2).

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (Paragraph 2.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

The appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

2.6.1.2 Tentatively Identified Compounds (Form I-TIC)

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-TIC is the tabulated list of the highest probable match for up to 10 of the nonsurrogate organic compounds not listed in Exhibit C, including the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentration. For estimating concentration, assume a response factor of 1, and estimate the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the

nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent (i.e., use peak height for all comparisons or use total area count for all comparisons).*

2.7 Pesticide/PCB Data

2.7.1 Sample Data

Sample data shall be arranged in packets with the Traffic Report copy, the Organic Analysis Data Sheet (Form I-PEST). The sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

2.7.1.1 Superfund-TCL Results - Organic Analysis Data Sheet (Form I-PEST).

Tabulated results (identification and quantitation) of the specified Superfund target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (reference 3.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

The appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to two significant figures for all pesticide/PCB samples.*

2.8 GC Organic Data

2.8.1 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet. These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

2.8.1.1 TCL Results - Organic Analysis Data Sheet.

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific signed statement in the SDG Narrative (Paragraph 2.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

The appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable. **NOTE**: Report analytical results to one significant figure if value is less than 10; two significant figures above 10.

2.9 Inorganic Data

Sample data shall be submitted with the Inorganic Analysis Data Reporting Forms for all samples in the SDG, arranged in increasing alphanumeric DEC sample number order.

2.9.1 Results -- Inorganic Analysis Data Sheet (FORM I-IN)

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I-CLP-IN. The quantitative values shall be reported in units of micrograms per liter (µg/L) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. No other units are acceptable. Results for solid sample must be reported on a dry weight basis. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

2.10 Toxicity Characteristic Leaching Procedure (TCLP) Data

Sample data shall be submitted with the Toxicity Characteristic Leaching Procedure Analysis Data Reporting Forms for all samples in the SDG, arranged in increasing alphanumeric DEC sample number order.

2.10.1 Results -- Toxicity Characteristic Leaching Procedure Analysis Data Sheet (FORM I-TCLP)

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I-TCLP. The quantitative values shall be reported in units of micrograms per liter (µg/L) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. No other units are acceptable. Results for solid sample must be reported on a dry weight basis. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

3.0 ASP Category B

3.1 SDG Narrative

This document shall be clearly labeled "SDG Narrative" and shall contain: Laboratory name; Case number; Sample Delivery Group number (SDG); sample numbers in the SDG, differentiating between initial analyses and re-analyses; Contract number; and detailed documentation of any quality control, sample, shipment and/or analytical problems encountered in processing the samples reported in the data package.

Whenever data from sample re-analysis are submitted, the Laboratory shall state in the SDG Narrative for each re-analysis, whether it considers the re-analysis to be billable, and if so, why.

The Laboratory must also include any problems encountered: both technical and administrative, corrective actions taken, and resolution and an explanation for all flagged edits (i.e., manual edits on quantitation lists.

The SDG Narrative shall contain the following statement, verbatim: "I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package and in the computer-readable data submitted on floppy diskette has been authorized by the Laboratory Manager or his designee, as verified by the following signature." This statement shall be directly followed by signature of the Laboratory Manager or his designee with a typed line below it containing the signer's name and title, and the date of signature.

Additionally, the SDG Narrative itself must be signed in original signature by the Laboratory Manager or his designee and dated.

3.2 Contract Lab Sample Information Sheets

A copy of the Contract Lab Sample Information Sheets (CLSIS) for all of the samples in the SDG. The CLSIS shall be arranged in increasing NYSDEC sample number order, considering both letters and numbering in ordering samples.

3.3 NYSDEC Data Package Summary Forms

3.4 Chain-of-Custody Forms

Copies of both the external and internal chain-of-custody sheets for all samples within the SDG.

3.5 GC/MS Volatiles Data

3.5.1 QC Summary

3.5.1.1 System Monitoring Compound Summary

3.5.1.2 Matrix Spike/Matrix Spike Duplicate Summary

3.5.1.3 QC Check Sample/Standard

3.5.1.4 Method Blank Summary

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank, by instrument.)

3.5.1.5 GC/MS Instrument Performance Check

BFB in chronological order; by instrument.

3.5.1.6 Instrument Detection Limits

3.5.2 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I-VOA, including Form I-VOA-TIC), followed by the raw data for volatile samples. These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

3.5.2.1 TCL Results - Organic Analysis Data Sheet (Form I-VOA).

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (Paragraph 3.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-VOA, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

3.5.2.2 Tentatively Identified Compounds (Form I-VOA-TIC).

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-VOA-TIC is the tabulated list of the highest probable match for up to 10 organic compounds not system monitoring compounds and not listed in Exhibit C for the appropriate program under which the samples were submitted, including the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentrations. For estimating concentration, assume a response factor of 1, and estimate the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent, i.e., use peak height for all comparisons or use total area count for all comparisons.*

3.5.2.3 Reconstructed Total Ion Chromatograms (RIC) for each sample or sample extract.

RICs must be normalized to the largest non-solvent component and contain the following header information:

- NYSDEC sample number
- Date and time of analysis
- GC/MS instrument ID

- Lab file ID

Internal standard and system monitoring compounds are to be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak. If automated system procedures are used for preliminary identification and/or quantification of the target compounds, the complete data system report must be included in all sample data packages in addition to the reconstructed ion chromatogram. The complete data system report shall include all of the information listed below. For laboratories which do not use the automated data system procedures, a laboratory "raw data sheet", which contains the following information, must be included in the sample data package in addition to the chromatogram.

- NYSDEC sample number
- Date and time of analysis
- RT or scan number of identified compounds
- Ion used for quantitation with measured area
- Copy of area table from data system
- GC/MS instrument ID
- Lab file ID

In all instances where the data system report has been edited, or where manual integration or quantitation has been performed, the GC/MS operator must identify such edits or manual procedures by initialing and dating the changes made to the report.

3.5.2.4 For each sample, by each compound identified, the following shall be included in the data package:

3.5.2.4.1 Copies of raw spectra and copies of background-subtracted mass spectra of target compounds listed in Exhibit C that are identified in the sample and corresponding background-subtracted TCL standard mass spectra. Spectra must be labeled with NYSDEC sample number, lab file ID, date and time of analysis, and GC/MS instrument ID; compound names must be clearly marked on all spectra.

3.5.2.4.2 Copies of mass spectra of organic compounds not listed in Exhibit C (Tentatively Identified Compounds) with associated best-match spectra (three best matches), labeled as in 3.5.2.4.1 above.

3.5.3 Standards Data

3.5.3.1 Initial Calibration Data (Form IV-VOA) - in order by instrument if more than one instrument used.

3.5.3.1.1 VOA standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for the initial calibration, labeled as in 3.5.2.3 above. Spectra are not required.

3.5.3.1.2 All initial calibration data that pertain to samples in the data package must be included, regardless of when it was performed and for which case. When more than one initial calibration is performed, the data must be put in chronological order, by instrument.

3.5.3.2 Continuing Calibration (Form VII-VOA) - in order by instrument, if more than one instrument used.

3.5.3.2.1 VOA standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for all continuing (12 hour) calibrations, labeled as in 3.5.2.3. Spectra are not required.

3.5.3.2.2 When more than one continuing calibration is performed, forms must be in chronological order, within fraction and instrument.

3.5.4 Raw QC Data

3.5.4.1 BFB (for each 12-hour period, for each GC/MS system utilized)

3.5.4.1.1 Bar graph spectrum, labeled as in 3.5.2.3.

3.5.4.1.2 Mass listing, labeled as in 3.5.2.3.

3.5.4.1.3 Reconstructed total ion chromatogram (RIC), labeled as in 3.5.2.3.

3.5.4.2 Blank Data - in chronological order.

***NOTE**: This order is different from that used for samples.*

3.5.4.2.1 Tabulated results (Form I-VOA)

3.5.4.2.2 Tentatively Identified Compounds (Form I-VOA-TIC) - even if none found.

3.5.4.2.3 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.4.2.3.

3.5.4.2.4 TCL spectra with lab generated standard, labeled as in 3.5.2.4. Data systems which are incapable of dual display shall provide spectra in the following order:

- Raw TCL compound spectra
- Enhanced or background subtracted spectra

- Laboratory generated TCL standard spectra

3.5.4.2.5 GC/MS library search spectra for Tentatively Identified Compounds (TIC), labeled as in 3.5.2.4.

3.5.4.2.6 Quantitation/Calculation of Tentatively Identified Compound(s) (TIC) concentrations

3.5.4.3 Matrix Spike Blank Data

3.5.4.3.1 Tabulated results (Form I-VOA) of all TCL compounds. Form I-VOA-TIC is not required.

3.5.4.3.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.5.2.4. Spectra are not required.

3.5.4.4 Matrix Spike Data

3.5.4.4.1 Tabulated results (Form I-VOA) of all TCL compounds. Form I-VOA-TIC is not required.

3.5.4.4.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.5.2.4. Spectra are not required.

3.5.4.5 Matrix Spike Duplicate Data

3.5.4.5.1 Tabulated results (Form I-VOA) of all TCL Compounds. Form I-VOA-TIC is not required.

3.5.4.5.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.5.2.4. Spectra are not required.

3.5.4.6 QC Check Sample/Standard

3.5.4.6.1 Tabulated results (Form I-VOA) of all TCL Compounds. Form I-VOA-TIC is not required.

3.5.4.6.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.5.2.4. Spectra are not required.

3.5.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

3.5.6 Copy of Extraction Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

3.6 GC/MS Semivolatiles Data

3.6.1 QC summary

3.6.1.1 Surrogate Percent Recovery Summary (Form II-SV)

3.6.1.2 Matrix Spike/Matrix Spike Duplicate Summary (Form III-SV)

3.6.1.3 QC Check Sample/Standard

3.6.1.4 Method Blank Summary (Form IV-SV)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank.)

3.6.1.5 GC/MS Instrument Performance and Mass Calibration (Form V-SV)

DFTPP in chronological order; by instrument.

3.6.1.6 Internal Standard Area and RT Summary (Form VIII-SV)

3.6.1.7 Instrument Detection Limits

3.6.2 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I-CLP-SV, including Form I SV-TIC), followed by the raw data for semivolatile samples. These sample packets should then be placed in increasing DEC sample number order, considering both letters and numbers in ordering samples.

3.6.2.1 TCL Results - Organic Analysis Data Sheet (Form I-SV-1, SV-2).

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (Paragraph 3.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-SV, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if the value is less than 10; to two significant figures above 10.*

3.6.2.2 Tentatively Identified Compounds (Form I-SV-TIC)

This form must be included even if no compounds are found. If so, indicate this on the form by entering "0" in the field for "Number found".

Form I-SV-TIC is the tabulated list of the highest probable match for up to 20 of the nonsurrogate organic compounds not listed in Exhibit C, including the CAS (Chemical Abstracts Registry) number, tentative identification and estimated concentration. For estimating concentration, assume a response factor of 1, and estimate the concentration by comparison of the compound peak height or total area count to the peak height or total area count of the nearest internal standard free of interferences on the reconstructed ion chromatogram.

***NOTE**: The Laboratory must be consistent (i.e., use peak height for all comparisons or use total area count for all comparisons).*

3.6.2.3 Reconstructed total ion chromatograms (RIC) for each sample, sample extract, standard, blank, and spiked sample.

RICs must be normalized to the largest nonsolvent component, and must contain the following header information:

- NYSDEC sample number
- Date and time of analysis
- GC/MS instrument ID
- Lab file ID

In all instances where the data system report has been edited, or where manual integration or quantitation has been performed, the GC/MS operator must identify such edits or manual procedures by initialing and dating the changes made to the report.

Internal standard and surrogate spiking compounds are to be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak. If automated data system procedures are used for preliminary identification and/or quantification of the Target Compound List compounds, the complete data system report must be included in all sample data packages, in addition to the reconstructed ion chromatogram. The complete data system report shall include all of the information listed below. For laboratories which do not use the automated data system procedures, a laboratory "raw data sheet," containing the following information, must be included in the sample data package in addition to the chromatogram.

- NYSDEC sample number
- Date and time of analysis

- RT or scan number of identified TCL compounds
- Ion used for quantitation with measured area
- Copy of area table from data system
- GC/MS instrument ID
- Lab file ID

3.6.2.4 For each sample, by each compound identified, the following shall be included in the data package:

3.6.2.4.1 Copies of raw spectra and copies of background-subtracted mass spectra of target compounds listed in Exhibit C that are identified in the sample and corresponding background-subtracted TCL standard mass spectra. Spectra must be labeled with NYSDEC sample number, lab file ID, date and time of analysis, and GC/MS instrument ID; compound names must be clearly marked on all spectra.

3.6.2.4.2 Copies of mass spectra of nonsurrogate organic compounds not listed in Exhibit C (Tentatively Identified Compounds) with associated best-match spectra (three best matches), labeled as in 3.6.2.3.

3.6.2.4.3 GPC chromatograms (if GPC performed).

3.6.3 Standards Data

3.6.3.1 Initial Calibration Data (Form VI-SV-1, SV-2) - in order by instrument, if more than one instrument used.

3.6.3.1.1 Semivolatile standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for the initial calibration, labeled in 3.6.2.3. Spectra are <u>not</u> required.

3.6.3.1.2 All initial calibration data that pertain to samples in the data package must be included, regardless of when it was performed and for which SDG. When more than one initial calibration is performed, the data must be put in chronological order, by instrument.

3.6.3.2 Continuing calibration (Form VII-SV-1, SV-2) - in order by instrument, if more than one instrument used.

3.6.3.2.1 Semivolatile standard(s) reconstructed ion chromatograms and quantitation reports (or legible facsimile) for all continuing (12 hour) calibrations, labeled as in 3.6.2.3. Spectra are <u>not</u> required.

3.6.3.2.2 When more than one continuing calibration is performed, forms must be in chronological order, by instrument.

3.6.3.3 Internal Standard Area Summary (Form VIII-SV-1, SV-2) in order by instrument, if more than one instrument used.

When more than one continuing calibration is performed, forms must be in chronological order by instrument.

3.6.3.4 Semivolatile GPC Calibration Data - UV detector traces showing peaks that correspond to the compounds in the semivolatile GPC calibration mixture. Traces must be labeled with GPC column identifier, date of calibration, and with compound names labeled either directly out from the peak, or on a printout of retention times, if retention times are printed over the peak. Do not include Form IX Pest-2, as the compounds used on that form are not appropriate for semivolatile sample extracts.

3.6.4 Raw QC Data

3.6.4.1 DFTPP (for each 12-hour period, for each GC/MS system utilized)

3.6.4.1.1 Bar graph spectrum, labeled as in 3.6.2.3.

3.6.4.1.2 Mass listing, labeled as in 3.6.2.3.

3.6.4.1.3 Reconstructed total ion chromatogram (RIC), labeled as in 3.6.2.3.

3.6.4.2 Blank Data - in chronological order, by extraction date.
NOTE: This order is different from that used for samples.

3.6.4.2.1 Tabulated results (Form I-SV-1, SV-2)

3.6.4.2.2 Tentatively Identified Compounds (Form I-SV-TIC) - even if none found.

3.6.4.2.3 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.6.2.3.

3.6.4.2.4 Superfund-TCL spectra with lab generated standard, labeled as in 3.6.2.4. Data systems which are incapable of dual display shall provide spectra in order:

- Raw TCL compound spectra
- Enhanced or background subtracted spectra
- Laboratory generated TCL standard spectra

3.6.4.2.5 GC/MS library search spectra for Tentatively Identified Compounds (TIC), labeled as in 3.6.2.4.

3.6.4.2.6 Quantitation/Calculation of Tentatively Identified Compound(s) (TIC) concentrations

3.6.4.3 Matrix Spike Blank Data

3.6.4.3.1 Tabulated results (Form I-SV-1, SV-2) of all TCL compounds. Form I-SV-TIC not required.

3.6.4.3.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.6.2.3. Spectra are required.

3.6.4.4 Matrix Spike Data

3.6.4.4.1 Tabulated results (Form I-SV-1, SV-2) of all TCL compounds. Form I-SV-TIC not required.

3.6.4.4.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.6.2.3. Spectra are not required.

3.6.4.5 Matrix Spike Duplicate Data

3.6.4.5.1 Tabulated results (Form I-SV-1, SV-2) of all TCL compounds. Form I-SV-TIC not required.

3.6.4.5.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.6.2.3. Spectra are not required.

3.6.4.6 QC Check Sample/Standard

3.6.4.6.1 Tabulated results (Form I-SV-1,SV-2) of all TCL compounds.

3.6.4.6.2 Reconstructed ion chromatogram(s) and quantitation report(s) or legible facsimile (GC/MS), labeled as in 3.6.2.3. Spectra are not required.

3.6.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

3.6.6 Copy of Extraction Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

3.7 GC/ECD Pesticide/Aroclor Data

3.7.1 QC Summary

3.7.1.1 Surrogate Percent Recovery Summary (Form II-PEST)

3.7.1.2 Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank Summary (Form III-PEST)

3.7.1.3 QC Check Sample/Standard Recovery

3.7.1.4 Method Blank Summary (Form IV-PEST)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank.)

3.7.1.5 Instrument Detection Limits

3.7.2 Sample Data

Sample data shall be arranged in packets with the Traffic Report copy, the Organic Analysis Data Sheet (Form I-PEST), followed by the raw data for pesticide samples. The sample packets should then be placed in increasing NYSDEC sample number order, considering both letters and numbers in ordering samples.

3.7.2.1 TCL Results - Organic Analysis Data Sheet (Form I-PEST).

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific, signed statement in the SDG Narrative (Paragraph 3.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-PEST, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

NOTE: Report analytical results to two significant figures for all pesticide/PCB samples.

3.7.2.2 Copies of pesticide chromatograms.

All chromatograms must be labeled with the following information.

- NYSDEC sample number
- Volume injected (µl)
- Date and time of injection
- GC column identification (by stationary phase and internal diameter)
- GC instrument identification
- Positively identified compounds must be labeled with the names of compounds, either directly out from the peak, or on a print-

out of retention times if retention times are printed over the peak.

3.7.2.3 Copies of pesticide chromatograms from second GC column confirmation. Chromatograms to be labeled as in 3.7.2.2 above.

3.7.2.4 GC integration report or data system printout and calibration plots (area vs. concentration) for 4-4'-DDT, 4,4'-DDD, 4,4'-DDE or toxaphene (where appropriate).

3.7.2.5 Manual work sheets.

3.7.2.6 UV traces from GPC (if GPC performed).

3.7.2.7 If pesticide/Aroclors are confirmed by GC/MS, the Laboratory shall submit copies of reconstructed ion chromatograms, raw spectra and copies of background-subtracted mass spectra of Superfund target compounds listed in Exhibit C (Superfund-TCL) that are identified in the sample and corresponding background-subtracted Superfund-TCL standard mass spectra. Compound names must be clearly marked on all spectra. For multicomponent pesticides/Aroclors confirmed by GC/MS, the Laboratory shall submit mass spectra of 3 major peaks of multicomponent compounds from samples and standards.

3.7.3 Standards Data

3.7.3.1 Initial Calibration of Single Component Analytes (Form VI-PEST-1 and PEST-2) - all GC columns, all instruments, in chronological order by GC column and instrument.

3.7.3.2 Initial Calibration of Multicomponent Analytes (Form VI-PEST-3) - all GC columns, all instruments, in chronological order by GC column and instrument

3.7.3.3 Analyte Resolution Summary (Form VI-PEST-4) - all GC columns and instruments, in chronological order by GC column and instrument.

3.7.3.4 Calibration Verification Summary (Form VII-PEST-1) - for all Performance Evaluation Mixtures and Instrument blanks, on all GC columns and instruments, in chronological order by GC column and instrument.

3.7.3.5 Calibration Verification Summary (Form VII-PEST-2) - for all mid point concentrations of Individual Standard Mixtures A and B and Instrument blanks used for calibration verification, on all GC columns and instruments, in chronological order by GC column and instrument.

3.7.3.6 Analytical Sequence (Form VIII-PEST) - all GC columns and instruments, in chronological order by GC column and instrument.

3.7.3.7 Florisil Cartridge Check (Form IX-PEST-1) - for all lots of cartridges used to process samples in the SDG.

3.7.3.8 Pesticide GPC Calibration (Form IX-PEST-2) - all GPC columns, in chronological order by calibration date.

3.7.3.9 Pesticide Identification Summary for Single Component Analytes (Form X-PEST-1) - for all samples with positively identified single component analytes, in order by increasing NYSDEC sample number.

3.7.3.10 Pesticide Identification Summary for Multicomponent Analytes (Form X-PEST-2) - for all samples with positively identified multicomponent analytes, in order by increasing NYSDEC sample number.

3.7.3.11 Chromatograms and data system printouts are required for all standards including the following:

- Resolution Check Mixture.
- Performance Evaluation Mixtures, all.
- Individual Standard Mixture A, at three concentrations, each initial calibration.
- Individual Standard Mixture B, at three concentrations, each initial calibration.
- All multicomponent analytes (Toxaphene and Aroclors), each initial calibration.
- All mid point concentrations of Individual Standard Mixtures A and B used for calibration verification.
- Florisil cartridge check solution, all lots.
- Pesticide GPC Calibration Check Solution, all calibrations relating to samples in the SDG.
- All multicomponent analyte standards analyzed for confirmation.

3.7.3.12 A printout of retention times and corresponding peak areas or peak heights must accompany each chromatogram. In addition, all chromatograms are required to be labeled with the following:

- NYSDEC Sample Number for the standard, i.e., INDA1, INDA2, etc. (See Forms Instructions for details).
- Label all standard peaks for all individual compounds either directly out from the peak or on the printout of retention times if retention times are printed over the peak.
- Total nanograms injected for each standard.
- Date and time of injection.
- GC column identification (by stationary phase and internal diameter).

- GC instrument identification.

3.7.3.13 Pesticide GPC Calibration Data - UV detector traces showing peaks that correspond to the compounds in the pesticide GPC calibration mixture. Traces must be labeled with GPC column identifier, date of calibration, and with compound names labeled either directly out from the peak, or on a printout of retention times, if retention times are printed over the peak.

3.7.4 Raw QC Data

3.7.4.1 Blank Data - in chronological order, by type of blank (method, instrument, sulfur cleanup).

***NOTE**: This order is different from that used for samples.*

3.7.4.1.1 Tabulated results (Form I-PEST).

3.7.4.1.2 Chromatogram(s) and data system printout(s) (GC) for each GC column and instrument used for analysis, labeled as in 3.7.2.2 above.

3.7.4.2 Matrix Spike Data

3.7.4.2.1 Tabulated results (Form I-PEST) of <u>all</u> TCL compounds.

3.7.4.2.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.7.2.2 above.

3.7.4.3 Matrix Spike Duplicate Data

3.7.4.3.1 Tabulated results (Form I-PEST) of <u>all</u> TCL compounds.

3.7.4.3.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.7.2.2 above

3.7.4.4 Matrix Spike Blank Data

3.7.4.4.1 Tabulated results (Form I-PEST) of <u>all</u> TCL compounds.

3.7.4.4.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.7.2.2 above

3.7.4.5 QC Check Sample/Standard

3.7.4.5.1 Tabulated results (Form I-PEST) of <u>all</u> TCL compounds.

3.7.4.5.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.7.2.2 above.

3.6.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

3.6.6 Copy of Extraction Log

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

3.8 GC Organic Data

3.8.1 QC Summary

3.8.1.1 Surrogate Percent Recovery Summary (Form II-GC)

3.8.1.2 Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank Summary (Form III-GC)

3.8.1.3 QC Check Sample/Standard

3.8.1.3.1 Tabulated results (Form I-PEST) of <u>all</u> TCL compounds.

3.8.1.3.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.8.2.2.

3.8.1.4 Method Blank Summary (Form IV-GC)

(If more than a single form is necessary, forms must be arranged in chronological order by date of analysis of the blank.)

3.8.1.5 Instrument Detection Limits

3.8.2 Sample Data

Sample data shall be arranged in packets with the Organic Analysis Data Sheet (Form I GC), followed by the raw data for pesticide samples. These sample packets should then be placed in increasing NYSDEC sample number order, considering both letters and numbers in ordering samples.

3.8.2.1 TCL Results - Organic Analysis Data Sheet (Form I-GC).

Tabulated results (identification and quantitation) of the specified target compounds (Exhibit C). The validation and release of these results is authorized by a specific signed statement in the SDG Narrative (Paragraph 3.1). In the event that the Laboratory Manager cannot validate all data reported for each sample, the Laboratory Manager shall provide a detailed description of the problems associated with the sample in the SDG Narrative.

On Form I-GC, the appropriate concentration units shall be entered. For example, µg/L for water samples or µg/Kg for soil/sediment samples. No other units are acceptable.

***NOTE**: Report analytical results to one significant figure if value is less than 10; two significant figures above 10.*

3.8.2.2 Copies of chromatograms.

All chromatograms must be labeled with the following information:

- NYSDEC sample number
- Volume injected (µL)
- Date and time of injection
- GC column identification (by stationary phase)
- GC instrument identification
- Positively identified compounds must be labeled with the names of compounds, either directly out from the peak, or on a print-out of retention times if retention times are printed over the peak.

3.8.2.3 Copies of chromatograms from second GC column confirmation. Chromatograms to be labeled as in 3.8.2.2.

3.8.2.4 GC integration report or data system printout and calibration plots (area vs. concentration) (where appropriate).

3.8.2.5 Manual work sheets.

3.8.2.6 GPC chromatograms (if GPC performed).

3.8.3 Standards Data

3.8.3.1 Initial Calibration Data

3.8.3.2 Continuing Calibration Data

3.8.3.3 QC Check Sample/Standard (as required per method)

3.8.3.4 Standard chromatograms and data system printouts for <u>all</u> standards.

3.8.3.4.1 All chromatograms are required to have the following:

- Label all standard peaks for all individual compounds either directly out from the peak or on the printout of retention times if retention times are printed over the peak.

- Label the chromatogram for multicomponent standards.
- List total ng injected for each standard.
- A printout of retention times and corresponding peak areas must accompany each chromatogram.
- Date and time of injection.
- GC column identification (by stationary phase).
- GC instrument identification.

3.8.4 Raw QC Data

3.8.4.1 Blank Data - in chronological order.

***NOTE**: This order is different from that used for samples.*

3.8.4.1.1 Tabulated results.

3.8.4.1.2 Chromatogram(s) and data system printout(s) (GC) for each GC column and instrument used for analysis.

3.8.4.2 Matrix Spike Data

3.8.4.2.1 Tabulated results of all TCL compounds.

3.8.4.2.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.8.2.2.

3.8.4.3 Matrix Spike Duplicate Data

3.8.4.3.1 Tabulated results of all TCL compounds.

3.8.4.3.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.8.2.2.

3.8.4.4 QC Check Sample/Standard

3.8.4.4.1 Tabulated results of all TCL compounds.

3.8.4.4.2 Chromatogram(s) and data system printout(s) (GC), labeled as in 3.8.2.2.

3.8.5 Copy of Calculations

The Laboratory must provide a copy of the calculations work sheet showing how final results are obtained from values printed on the quantitation report. If manipulations are performed by a software package, a copy of the formula used must be supplied as well as values for all terms in the formula.

3.8.6 Copy of Extraction Log

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. matrix spike, matrix spike duplicate, matrix spike blank) correspond to each batch extracted, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) final volumes and vial identification numbers.

3.9 Inorganic Data

Sample data shall be submitted with the Inorganic Analysis Data Reporting Forms for all samples in the SDG, arranged in increasing alphanumeric DEC sample number order, followed by the QC analyses data, Quarterly Verification of Instrument Parameters forms, raw data, and copies of the digestion and distillation logs.

3.9.1 Results -- Inorganic Analysis Data Sheet (Form I-IN)

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I-IN. The quantitative values shall be reported in units of micrograms per liter (µg/L) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. No other units are acceptable. Results for solid sample must be reported on a dry weight basis. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

3.9.2 Quality Control Data

3.9.2.1 Initial and Continuing Calibration Verification [FORM II-IN (Part 1)]

3.9.2.2 CRDL Standard for AA and Linear Range Analysis for ICP [FORM II-IN (PART 2)]

3.9.2.3 Blanks [FORM III-IN]

3.9.2.4 ICP Interference Check Sample [FORM IV-IN]

3.9.2.5 Spike Sample Recovery [FORM V-IN (PART 1)]

3.9.2.6 Post Digest Spike Sample Recovery [FORM V-IN (PART 2)]

3.9.2.7 Duplicates [FORM VI-IN]

3.9.2.8 Quality Control Sample [FORM VII-IN]

3.9.2.9 Standard Addition Results [FORM VIII-IN]

3.9.2.10 ICP Serial Dilutions [FORM IX-IN]

3.9.2.11 Holding Times [FORM X-IN]

3.9.3 Verification of Instrument Parameters

3.9.3.1 Instrument Detection Limits (Semiannually) [FORM XI-IN]

3.9.3.2 ICP Interelement Correction Factors (Annually) [FORM XII-IN (PART 1)]

3.9.3.3 ICP Interelement Correction Factors (Annually) [FORM XII-IN (PART 2)]

3.9.3.4 ICP Linear Ranges (Quarterly) [FORM XIII-IN]

(Note that copies of Verification of Instrument Parameters forms for the current quarter must be submitted with each data package.)

3.9.4 Raw Data

For each reported value, the Laboratory shall include in the data package all raw data from the instrument used to obtain that value. This applies to all required QA/QC measurements, instrument standardization, as well as sample results. This statement does not apply to the Verifications of Instrument Parameters submitted as part of each data package. Raw data must contain all instrument readouts used for the sample results, including those readouts that may fall below the IDL. All AA and ICP instruments must provide a legible hard copy of the direct real-time instrument readout (i.e., stripcharts, printer tapes, etc.). A photocopy of the direct sequential instrument readout must be included. A hardcopy of the instrument's direct instrument readout for cyanide must be included if the instrumentation has the capability.

The order of raw data in the data package shall be: ICP, Flame AA, Furnace AA, Mercury, and Cyanide. All raw data shall include intensities (ICP) and absorbances with concentration units for flame AA, furnace AA, Mercury and Cyanide. All flame and furnace AA data shall be grouped by element.

Raw data must be labeled with NYSDEC sample number and appropriate codes, shown in Table 1 following to unequivocally identify:

3.9.4.1 Calibration standards, including source and prep date.

3.9.4.2 Initial and continuing calibration blanks and preparation blanks.

3.9.4.3 Initial and continuing calibration verification standards, interference check samples, ICP serial dilution samples, CRDL Standard for ICP and AA, Laboratory Control Sample and Post Digestion Spike.

3.9.4.4 Diluted and undiluted samples (by DEC sample number) and all weights, dilutions and volumes used to obtain the reported values. (If the volumes, weights and dilutions are consistent for all samples in a given SDG, a general statement outlining these parameters is sufficient).

3.9.4.5 Duplicates.

3.9.4.6 Spikes (indicating standard solutions used, final spike concentrations, volumes involved). If spike information (source, concentration, volume) is consistent for a given SDG, a general statement outlining these parameters is sufficient.

3.9.4.7 Instrument used, any instrument adjustments, data corrections or other apparent anomalies on the measurement record, including all data voided or data not used to obtain reported values and a brief written explanation.

3.9.4.8 All information for furnace analysis clearly and sequentially identified on the raw data, including NYSDEC sample number, sample and analytical spike data, percent recovery, coefficient of variation, full MSA data, MSA correlation coefficient, full MSA data, MSA correlation coefficient, slope and intercepts of linear fit, final sample concentration (standard addition concentration), and type of background correction used: BS for Smith-Heiftje, BD for deuterium Arc, or BZ for Zeeman.

3.9.4.9 Time and date of each analysis. Instrument run logs can be submitted if they contain this information. If the instrument does not automatically provide times of analysis, these must be manually entered on all raw data for initial and continuing calibration verification and blanks, as well as interference check samples and linear range analysis.

3.9.4.10 Integration times for AA analyses.

3.9.5 Digestion Logs

Logs shall be submitted in the following order: digestion logs for ICP, flame AA, furnace AA and mercury preparations, followed by a copy of the distillation log for cyanide. These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. laboratory control sample, preparation blank) correspond to each batch digested, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) indication of pH <2 or >12, as applicable.

3.10 Wet-Chemical Data

Sample data shall be submitted with the Conventional Analysis Data Reporting Forms for all sample in the SDG, arranged in increasing alphanumeric NYSDEC sample number order, followed by the QC analyses data, Quarterly Verification of Instrument Parameters forms, raw data, and copies of the digestion and distillation logs.

3.10.1 Results -- Wet-Chemical Analysis Data Sheet

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I. The quantitative values shall be reported in units of micrograms per liter (µg/L) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. No other units are acceptable. Results for solid samples must be reported on a dry weight basis. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

3.10.2 Quality Control Data

3.10.2.1 Initial and Continuing Calibration Verification

3.10.2.2 CRQL Standard for Wet-Chemical Analysis

3.10.2.3 Blanks

3.10.2.4 Spike Sample Recovery

3.10.2.5 Post Digest Spike Sample Recovery

3.10.2.6 Duplicates

3.10.2.7 Laboratory Control Sample

3.10.2.8 Holding Times

3.10.3 Raw Data

For each reported value, the Laboratory shall include in the data package all raw data from the instrument used to obtain that value and the QA/QC values reported (except for raw data for quarterly verifications of instrument parameters). Raw data must contain all instrument readouts used for the sample results, including those readouts that may fall below the IDG. ALL instruments must provide a legible hard copy of the direct real-time instrument readout (i.e., stripcharts, printer tapes, etc.). A photocopy of the direct sequential instrument readout must be included. A hardcopy of the direct instrument readout for cyanide must be included if the instrumentation has the capability. All raw data shall include absorbances with concentration units (unless instrument direct readout is in

concentration units). A photocopy of manual worksheets used must be included for all non-instrumental parameters.

Raw data must be labeled with NYSDEC sample number to unequivocally identify:

3.10.3.1 Calibration standards, including source and prep date.

3.10.3.2 Initial and continuing calibration blanks and preparation blanks.

3.10.3.3 Initial and continuing calibration verification standards.

3.10.3.4 Diluted and undiluted samples (by NYSDEC sample number) and all weights, dilutions and volumes used to obtain the reported values. (If the volumes, weights and dilutions are consistent for all samples in a given SDG, a general statement outlining these parameters is sufficient).

3.10.3.5 Duplicates.

3.10.3.6 Spikes (indicating standard solutions used, final spike concentrations, volumes involved). If spike information (source, concentration, volume) is consistent for a given SDG, a general statement outlining these parameters is sufficient.

3.10.3.7 Instrument used, any instrument adjustments, data corrections or other apparent anomalies on the measurement record, including all data voided or data not used to obtain reported values and a brief written explanation.

3.10.3.8 Time and date of each analysis. Instrument run logs can be submitted if they contain this information. If the instrument does not automatically provide times of analysis, these must be manually entered on all raw data for initial and continuing calibration verification and blanks, as well as interference check samples and linear range analysis.

3.10.4 Digestion and Distillation Logs

These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e., laboratory control sample, preparation blank) correspond to each batch digested, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) indication of pH <2 or >12, as applicable.

3.11 Toxicity Characteristic Leaching Procedure (TCLP) Data

Sample data shall be submitted with the Toxicity Characteristic Leaching Procedure Analysis Data Reporting Forms for all samples in the SDG, arranged in increasing alphanumeric DEC sample number order, followed by the QC analyses data, Quarterly Verification of Instrument Parameters forms, raw data, and copies of the digestion and distillation logs.

3.11.1 Results -- Toxicity Characteristic Leaching Procedure (TCLP) Analysis Data Sheet (Form I-TCLP)

Tabulated analytical results (identification and quantitation) of the specified analytes (Exhibit C). The validation and release of these results is authorized by a specific, signed statement on the Cover Page. If the Laboratory Manager cannot validate all data reported for each sample, he/she must provide a detailed description of the problems associated with the sample(s) on the Cover Page.

Appropriate concentration units must be specified and entered on Form I-IN. The quantitative values shall be reported in units of milligrams per liter (mg/L). No other units are acceptable. Analytical results must be reported to two significant figures if the result value is less than 10; to three significant figures if the value is greater than or equal to 10. Results for percent solids must be reported to one decimal place.

3.11.2 TCLP Inorganic Quality Control Data

3.11.2.1 Initial and Continuing Calibration Verification [FORM II-IN (Part 1)]

3.11.2.2 CRDL Standard for AA and Linear Range Analysis for ICP [FORM II-IN (PART 2)]

3.11.2.3 Blanks [FORM III-IN]

3.11.2.4 ICP Interference Check Sample [FORM IV-IN]

3.11.2.5 Spike Sample Recovery [FORM V-IN (PART 1)]

3.11.2.6 Post Digest Spike Sample Recovery [FORM V-IN (PART 2)]

3.11.2.7 Duplicates [FORM VI-IN]

3.11.2.8 Quality Control Sample [FORM VII-IN]

3.11.2.9 Standard Addition Results [FORM VIII-IN]

3.11.2.10 ICP Serial Dilutions [FORM IX-IN]

3.11.2.11 Holding Times [FORM X-IN]

3.11.3 Verification of Instrument Parameters

3.11.3.1 Instrument Detection Limits (Semiannually) [FORM XI-IN]

3.11.3.2 ICP Interelement Correction Factors (Annually) [FORM XII-IN (PART 1)]

3.11.3.3 ICP Interelement Correction Factors (Annually) [FORM XII-IN (PART 2)]

3.11.3.4 ICP Linear Ranges (Quarterly) [FORM XIII-IN]

NOTE: *Copies of Verification of Instrument Parameters forms for the current quarter must be submitted with each data package.*

3.11.4 Raw Data

For each reported value, the Laboratory shall include in the data package all raw data from the instrument used to obtain that value. This applies to all required QA/QC measurements, instrument standardization, as well as sample results. This statement does not apply to the Verifications of Instrument Parameters submitted as part of each data package. Raw data must contain all instrument readouts used for the sample results, including those readouts that may fall below the IDL. All AA and ICP instruments must provide a legible hard copy of the direct real-time instrument readout (i.e., stripcharts, printer tapes, etc.). A photocopy of the direct sequential instrument readout must be included. A hardcopy of the instrument's direct instrument readout for cyanide must be included if the instrumentation has the capability.

The order of raw data in the data package shall be: ICP, Flame AA, Furnace AA, Mercury, and Cyanide. All raw data shall include intensities (ICP) and absorbances with concentration units for flame AA, furnace AA, Mercury and Cyanide. All flame and furnace AA data shall be grouped by element.

Raw data must be labeled with NYSDEC sample number and appropriate codes, shown in Table 1 following to unequivocally identify:

3.11.4.1 Calibration standards, including source and prep date.

3.11.4.2 Initial and continuing calibration blanks and preparation blanks.

3.11.4.3 Initial and continuing calibration verification standards, interference check samples, ICP serial dilution samples, CRDL Standard for ICP and AA, Laboratory Control Sample and Post Digestion Spike.

3.11.4.4 Diluted and undiluted samples (by DEC sample number) and all weights, dilutions and volumes used to obtain the reported values. (If the volumes, weights and dilutions are consistent for all samples in a given SDG, a general statement outlining these parameters is sufficient).

3.11.4.5 Duplicates.

3.11.4.6 Spikes (indicating standard solutions used, final spike concentrations, volumes involved). If spike information (source, concentration, volume) is consistent for a given SDG, a general statement outlining these parameters is sufficient.

3.11.4.7 Instrument used, any instrument adjustments, data corrections or other apparent anomalies on the measurement record, including all data voided or data not used to obtain reported values and a brief written explanation.

3.11.4.8 All information for furnace analysis clearly and sequentially identified on the raw data, including NYSDEC sample number,

sample and analytical spike data, percent recovery, coefficient of variation, full MSA data, MSA correlation coefficient, full MSA data, MSA correlation coefficient, slope and intercepts of linear fit, final sample concentration (standard addition concentration), and type of background correction used: BS for Smith-Heiftje, BD for deuterium Arc, or BZ for Zeeman.

3.11.4.9 Time and date of each analysis. Instrument run logs can be submitted if they contain this information. If the instrument does not automatically provide times of analysis, these must be manually entered on all raw data for initial and continuing calibration verification and blanks, as well as interference check samples and linear range analysis.

3.11.4.10 Integration times for AA analyses.

3.11.5 Digestion Logs

Logs shall be submitted in the following order: digestion logs for ICP, flame AA, furnace AA and mercury preparations, followed by a copy of the distillation log for cyanide. These logs must include: (1) date, (2) sample weights and volumes, (3) sufficient information to unequivocally identify which QC samples (i.e. laboratory control sample, preparation blank) correspond to each batch digested, (4) comments describing any significant sample changes or reactions which occur during preparation, and (5) indication of pH <2 or >12, as applicable.

F. - Data In Computer Readable Form

Exhibit H details the requirements for data in computer-readable form. The specific requirements depend on the reporting category requested (Superfund, A, or B) and the analytical method used.

The Laboratory shall provide a computer-readable copy of the data on data report Forms I-XIV for all samples in the Delivery Group, as specified in the Contract Performance/Delivery Schedule. Computer-readable data deliverables shall be submitted on IBM or IBM-compatible 3.5 inch high density 1.44 M-byte diskette. The data shall be recorded in ASCII, text file format, and shall adhere to the file, record and field specifications listed in Exhibit H, Data Dictionary and Format for Data Deliverables in Computer-Readable Format.

DEC is still in the process of developing the Data Dictionary for GC Organics and Wet-Chemistry Parameters. This information will be provided to the laboratory when it becomes available.

When submitted, floppy diskettes shall be packaged and shipped in such a manner that the diskette(s) cannot be bent or folded, and will not be exposed to extreme heat or cold or any type of electromagnetic radiation. The diskette(s) must be included in the same shipment as the hardcopy data and shall, at a minimum, be enclosed in a diskette mailer.

G. - GC/MS Tapes

The Laboratory must store <u>all</u> raw and processed GC/MS data on magnetic tape, in appropriate instrument manufacturer's format. This tape must include data for samples, blanks, matrix spikes, matrix spike duplicates, initial calibrations, continuing calibrations, BFB and DFTPP, as well as all laboratory-generated spectral libraries and quantitation reports required to generate the data package. The Laboratory shall maintain a written

reference logbook of tape files to DEC sample number, calibration data, standards, blanks, matrix spikes, and matrix spike duplicates. The logbook should include DEC sample numbers and standard and blank ID's, identified by Case and Sample Delivery Group.

The Laboratory is required to retain the GC/MS tapes for 365 days after data submission. During that time, the Laboratory shall submit tapes and associated logbook pages within seven days after receipt of a written request from the Bureau of Watershed Assessment and Research.

See Exhibit E for specific requirements.

H. - Extracts

The Laboratory shall preserve sample extracts at 4°C (±2°C) in bottles/vials with Teflon-lined septa. Extract bottles/vials shall be labeled with NYSDEC sample number, Case number and Sample Delivery Group (SDG) number. A logbook of stored extracts shall be maintained, listing NYSDEC sample number and associated Case and SDG numbers.

The Laboratory is required to retain extracts for 90 days following data submission. During that time, the Laboratory shall submit extracts and associated logbook pages within seven days following receipt of a written request from the Bureau of Technical Services and Research or the Project Officer.

I. - Complete SDG File Purge

As specified in the Delivery Schedule, one Complete SDG File (CSF) including the original Sample Data Package shall be delivered to the BWAR concurrently with delivery of the Sample Data Package to the sample submitter or Project Director. The contents of the CSF will be numbered according to the specifications described in Section III and IV of Exhibit B. The Document Inventory Sheet, Form DC-2, is contained in Section IV. The CSF will contain all original documents where possible. No copies will be placed in the CSF unless the originals are bound in a logbook which is maintained by the Laboratory. The CSF will contain all original documents specified in Section III and IV, and Form DC-2 of Exhibit B of this Protocol.

The CSF will consist of the following original documents in addition to the documents in the Sample Data Package:

1. Original Sample Data Package

2. A completed and signed Document Inventory Sheet (Form DC-2).

3. All original shipping documents, including, but not limited to, the following documents:

    a. NYSDEC Chain of Custody Record.

    b. Airbills.

    c. NYSDEC Contract Lab Sample Information Sheets.

    d. Sample Tags (if present) sealed in plastic bags.

4. All original receiving documents, including, but not limited to, the following documents:

a. Form DC-1.

b. Other receiving forms or copies of receiving logbooks.

c. SDG Cover Sheet.

5. All original laboratory records, not already submitted in the Sample Data Package, of sample transfer, preparation and analysis, including, but not limited to, the following documents:

a. Original preparation and analysis forms or copies of preparation and analysis logbook pages.

b. Internal sample and sample extract transfer chain-of-custody records.

c. Screening records.

d. All instrument output, including strip charts from screening activities.

6. All other original SDG-specific documents in the possession of the Laboratory, including, but not limited to, the following documents:

a. Telephone contact logs.

b. Copies of personal logbook pages.

c. All hand written case-specific notes.

d. Any other case-specific documents not covered by the above.

***NOTE**: All Case-related documentation may be used or admitted as evidence in subsequent legal proceedings. Any other Case-specific documents generated after the CSF is sent to NYSDEC, as well as copies that are altered in any fashion, are also deliverables to NYSDEC.*

If the Laboratory does submit SDG-specific documents to NYSDEC after submission of the CSF, the documents should be numbered as an addendum to the CSF and a revised DC-2 form should be submitted, or the documents should be numbered as a new CSF and a new DC-2 form should be submitted to the BWAR only.

(Formerly, Document Control and Chain-of-Custody Package).

The Complete SDG File Purge includes all laboratory records received or generated for a specific SDG that have not been previously submitted to DEC as a deliverable. These items include but are not limited to: sample tags, custody records, sample tracking records, analysts logbook pages, bench sheets, chromatographic charts, computer printouts, raw data summaries, instrument logbook pages, correspondence, and the document inventory (see Exhibit F).

Shipment of the Complete SDG File Purge package by first class mail, overnight carrier, priority mail or equivalent is acceptable. Custody seals must be placed on shipping containers and a document inventory and transmittal letter included. The Laboratory is not required to maintain any documents for a sample SDG after submission of the

Complete SDG File Purge package; however, the Laboratory should maintain a copy of the document inventory and transmittal letter.

J. - Semiannual Verification of Instrument Parameters

The Laboratory shall perform and report semiannually verification of instrument detection limits and linear range by methods specified in Exhibit E for each instrument used under this Protocol. For the ICP instrumentation and methods, the Laboratory shall also report annually interelement correction factors (including method of determination), wavelengths used, and integration times. Semiannual Verification of Instrument Parameters forms for the current period shall be submitted in each Sample Delivery Group data package, using Forms X, XI and XII. Submission of Semiannual Verification of Instrument Parameters shall include the raw data used to determine those values reported.

Section III -- CLP Reporting Forms and Instruction Guide

Required Organic and Inorganic Reporting forms and instructions for completion of the forms can be found in Exhibit D, CLP.

Section IV -- NYSDEC Data Package Summary Forms

I. Sample Identification and Analytical Requirement Summary (Page 1 of 6)

A. Customer Sample Code

Sample code number (assigned by sampling crew). A number must be given to each sample to be analyzed and documented on form.

B. Laboratory Sample Code

Code number given to respective sample by the laboratory and used for identification throughout analysis. If sample receives laboratory sample numbers, please indicate on page 1.

C. Analytical Requirements

1. Check appropriate boxes for parameters to be analyzed.

2. Circle either CLP or Non-CLP and enter year of protocol. If non-CLP, circle type of analyses needed, if necessary, provide analysis as an attachment sheet.

II. Sample Preparation and Analysis Summary, B/N-A, Pesticides/PCB's and VOA

(Pages 2,3,4 of 7)

A. Sample ID

The sample code number which the laboratory will use throughout the analysis for a specific sample.

B. Matrix

Label the sample with matrix of either water, soil, oil, grease, drum solvent, etc.

C. Date Collected

Record the date that sample was collected on site.

D. Date Received at Laboratory

Record the date the Laboratory received the sample. (Verified Time of Sample Receipt - VTSR)

E. Date Extracted

Record the date the sample was extracted.

F. Date Analyzed

Record the date the sample was analyzed.

III. Sample Preparation and Analysis Summary - Organic Analysis

A. Sample ID

The sample code number which the laboratory will use throughout analysis for a specific sample.

B. Matrix

Label the sample with the specific matrix (see #B).

C. Analytical Protocol

Record year and Protocol used (i.e., 2000 NYSDEC ASP or 1989 NYSDEC ASP - Revision 10/95). If non-CLP, list number of method used.

D. Extraction Method

Write the method used for sample extraction.

E. Auxiliary Clean-Up

If cleanup was done on sample, record the method or methods used.

F. Dil/Con Factor

If sample was diluted, record the dilution factor, or if concentrated, record also.

IV. Sample Preparation and Analysis Summary - Inorganics Analysis

A. Sample ID and Matrix columns are completed following procedures for VOA, BNA, Pesticides/PCB's.

B. Metals Requested

List metals that are to be analyzed. If for NYSDEC ASP, write full TCL in column, or more individual metals required.

C. Date Received - VTSR

D. Date Digested

E. Date Analyzed

Date sample was analyzed on instrument.

To be included with all lab data and with each workplan

Section V -- NYSDEC Division Of Solid and Hazardous Materials 6 NYCRR Part 360 Parameters 57

Introduction

NOTE: The values in these tables are quantitation limits, not absolute detection limits. The amount of material necessary to produce a detector response that can be identified and reliably quantified is greater than that needed to simply be detected above the background noise. The quantitation limits in these tables are set at the concentrations in the sample equivalent to the concentration of the lowest calibration standard analyzed for each analyte.

Specific quantitation limits are highly matrix dependent. The quantitation limits listed herein are provided for guidance and may not always be achievable.

CRQL values listed on the following pages are based on the analysis of samples according to the specifications given in Exhibit D. For each fraction and matrix, a brief synopsis of the sample handling and analysis steps is given, along with an example calculation for the CRQL value. All CRQL values are rounded to two significant figures. For soil samples, the moisture content of the samples is not considered in these example calculations.

* Quantitation Limits listed for soil/sediment are based on wet weight. The quantitation limits calculated by the laboratory for soil/sediment, calculated on dry weight basis, as required by the protocol, will be higher.

Note that the CRQL values listed on the preceding page may not be those specified in previous Analytical Services Protocols. These values are set at concentrations in the sample equivalent to the concentration of the lowest calibration standard specified in Exhibit D, Part II. Lower quantitation limits may be achievable for water samples by employing the methods in Exhibit D, Part X for Low Concentration Water for Organic Analyses.

VOLATILES

Water Samples

A 5 mL volume of water is purged with an inert gas at ambient temperature. The volatiles are trapped on solid sorbents, and desorbed directly onto the GC/MS. For a sample with compound X at the CRQL of 10 µg/L:

(10 µg/L) (5 mL) (10^{-3} L/mL) = 50 x 10^{-3} ug = 50 ng on the GC column

Low Level Soil/Sediment Samples

A 5 g aliquot of the soil/sediment sample is added to a volume of water in a purge tube, heated, and purged with an inert gas. The volatiles are trapped, and later desorbed directly onto the GC/MS. For a sample with compound X at the CRQL of 10 µg/Kg:

(10 µg/Kg) (5 g) (10^{-3} Kg/g) = 50 x 10^{-3} µg = 50 ng on the GC column

Medium Level Soil/Sediment Samples

A 4 g aliquot of soil/sediment is extracted with 10 mL of methanol, and filtered through glass wool. Only 1 mL of the methanol extract is taken for screening and analysis. Based on the results of a GC/FID screen, an aliquot of the methanol extract is added to 5 mL of reagent water and purged at ambient temperature. The largest aliquot of extract considered in Exhibit D, Part III is 100 uL. For a sample with compound X at the CRQL of 1200 µg/Kg:

(1200 µg/Kg) (4 g) (10^{-3} Kg/g) = 4800 x 10^{-3} µg = 4800 ng

This material is contained in the 10 mL methanol extract:

(4800 ng) / 10 mL = 480 ng/mL

Of which, 100 µL are purged from the reagent water.

(480 ng/mL) (100 µL) (10^{-3} mL/µL) = 480 x 10^{-1} ng = 50 ng on the GC column

Note that for both low and medium soil/sediment samples, while it may affect the purging efficiency, the volume of reagent water used in the purging process does not affect the calculations.

SEMIVOLATILES

Water Samples

A 1 L volume of water is extracted in a continuous liquid-liquid extractor with methylene chloride at a pH of approximately 2. This extract is reduced in volume to 1.0 mL, and a 2 µL volume is injected onto the GC/MS for analysis. For a sample with compound X at the CRQL of 10 µg/L:

(10 µg/L) (1 L) = 10 µg in the original extract

When the extract is concentrated, this .material is contained in the 1 mL concentrated extract, of which 2 µL are injected into the instrument:

(10 µg/mL) (2 µL) (10^{-3} mL/µL) = 20 x 10^{-3} µg = 20 ng on the GC column

Low Soil Samples

A 30 g soil sample is extracted three times with methylene chloride/acetone at ambient pH, by sonication or Soxhlet. The extract is reduced in volume to 1.0 mL, and a 2 µL volume is injected onto the GC/MS for analysis. For a sample with compound X at the CRQL of 330 µg/Kg:

(330 µg/Kg) (30 g) (10^{-3} Kg/g) = 9900 x 10^{-3} µg = 9.9 µg

When the sample extract is to be subjected to Gel Permeation Chromatography (required) to remove high molecular weight interferences, the volume of the extract is initially reduced to 10 mL. This 10 mL is put through the GPC column, and only 5 mL are collected off the GPC. That 5 mL volume is reduced to 0.5 mL prior to analysis. Therefore:

(9.9 µg/10 mL) (5 mL) = 4.95 µg

This material is contained in the 0.5 mL extract, of which 2 µL are injected lnto the instrument:

(4.95 µg/0.5 mL) (2 µL) (10^{-3} mL/µL) = (1.98 x 10^{-2} µg) 20 ng on the GC column

Medium Soil Samples

A 1 g soil sample is extracted once with 10 mL of methylene chloride/acetone, which is filtered through glass wool to remove particles of soil. The filtered extract is then subjected to GPC clean up, and only 5 mL of extract are collected after GPC. This extract is reduced in volume to 0.5 mL, of which 2 µL are injected onto the GC/MS. For a sample with compound X at the CRQL of 10,000 µg/Kg:

(10,000 µg/Kg) (1 g) (10^{-3} Kg/g) = 10 µg

(continued)

Semivolatiles, Medium Soil, continued -

This material is contained in the 10 mL extract, of which only 5 mL are collected after GPC:

(10 µg) (5 mL/10 mL) = 5 ug

The volume of this extract is reduced to 0.5 mL, of which 2 µL are injected into the instrument:

(5 µg/0.5 mL) (2 µL) (10^{-3} mL/µL) = 20 x 10^{-3} ug = 20 ng on the GC column

Eight semivolatile compounds are calibrated using only a four point initial calibration, with the lowest standard at 50 ng. Therefore, the CRQL values for these eight compounds are 2.5 times higher for all matrices and levels.

PESTICIDES/AROCLORS

Water Samples

A 1 L volume of water is extracted three times with methylene chloride or by a continuous liquid-liquid extractor. This extract is reduced in volume to approximately 3 - 5 mL, and diluted up to 10.0 mL with clean solvent. When Gel Permeation Chromatography is performed, only 5 of the 10 mL of extract are collected after GPC.

Regardless of whether GPC is performed, either 1.0 or 2.0 mL of the 10.0 mL of the original extracts are taken through the remaining clean up steps (Florisil and sulfur removal). The volume taken through Florisil cleanup and the final volume of the extract after the clean up steps depends on the requirements of the autosampler. If the autosampler can handle 1.0 mL final extract volumes, this is the volume taken through Florisil and the final volume. If the autosampler cannot reliably handle 1.0 mL volumes, the volume is 2.0 mL. When using an autosampler, the injection volume may be 1.0 or 2.0 µL. Manual injections must use a 2.0 µL injection volume.

For a sample with compound X at the CRQL of 0.05 µg/L and an autosampler requiring a 1.0 mL volume:

(0.05 µg/L) (1 L) = 0.05 µg in the original extract

This material is contained in the 10.0 mL of extract:

(0.05 µg)/ (10.0 mL) = 0.005 µg/mL

Of which, only 1.0 mL is carried through the remaining clean up steps. For a final extract volume of 1.0 mL and a 1 µL injection volume:

(0.005 µg/L) (1 µL) (10^{-3} mL/µL) = 5 x 10^{-6} µg = 5 pg on the GC column

Soil Samples

There is no differentiation between the preparation of low and medium soil samples in this method for the analysis of pesticides/Aroclors. A 30 g soil sample is extracted three times with methylene chloride/acetone by sonication or Soxhlet extraction. The extract is reduced in volume to 10.0 mL and subjected to Gel Permeation Chromatography. After GPC, only 5.0 mL of extract are collected. However, as with the water sample described above, either 1.0 or 2.0 mL of that extract are subjected to the other clean up steps, so no loss of sensitivity results from the use of GPC. From this point on, the soil sample extract is handled in the same fashion as the extract of a water sample. For a sample with compound X at the CRQL of 1.7 µg/Kg:

(1.7 µg/Kg) (30 g) (10^{-3} Kg/g) = 51 x 10^{-3} µg = 51 ng in the original extract

This material is contained in the 10.0 mL of extract:

(51 ng)/10 mL = 5.1 ng/mL
(continued)

of which, only 1.0 or 2.0 mL are carried through the remaining cleanup steps For a final extract volume of 1.0 mL and a 1 µL injection volume:

$(5.1\ ng/mL)(1\ \mu L)(10^{-3}\ mL/\mu L) = 5.1 \times 10^{-3}\ ng = 5\ pg$ on the GC column.

For either water or soil samples, if the autosampler used requires a 2.0 mL final volume, the concentration in the 10.0 mL of extract above remains the same.

Using a 2 µL injection volume, twice the total number of picograms are injected onto the GC column. However, because the injection volume must be the same for samples and standards, twice as much material is injected onto the column during calibration, and thus the amount of compound X injected from the sample extract is equivalent to the amount of compound X injected from the calibration standard, regardless of injection volume.

If a single injection is used for two GC columns attached to a single injection part, it may be necessary to use an injection volume greater than 2 µL.

18.	Selenium	5
19.	Silver	10
20.	Sodium	5000
21.	Thallium	10
22.	Vanadium	50
23.	Zinc	20
24.	Cyanide	10

1: Any analytical method specified in Exhibit D, CLP-Inorganics may be utilized as long as the documented instrument or method detection limits meet the Contract Required Quantitation Level (CRQL) requirements. Higher quantitation levels may only be used in the following circumstance:

If the sample concentration exceeds five times the quantitation limit of the instrument or method in use, the value may be reported even though the instrument or method detection limit may not equal the Contract Required Quantitation Limit. This is illustrated in the example below:

For lead:
Method in use = ICP
Instrument Detection Limit (IDL) = 40
Sample concentration = 220
Contract Required Quantitation Level (CRQL) = 3

The value of 220 may be reported even though instrument detection limit is greater than Contract Required Quantitation Limit. The instrument or method detection limit must be documented as described in Exhibit E.

2: These CRQLs are the instrument detection limits obtained in pure water that must be met using the procedure in Exhibit E. The quantitation limits for samples may be considerably higher depending on the sample matrix.

Section III -- Regulatory Promulgated Parameters

In addition to the preceding lists, the Laboratory may be asked to analyze for any or all of the conventional water quality parameters as listed in 40CFR Part 136 or for the hazardous waste parameters listed in 40CFR Part 260 through 270.

Quantitation limits to be achieved for these analyses are specified.

METHOD 0010

MODIFIED METHOD 5 SAMPLING TRAIN

1.0 SCOPE AND APPLICATION

1.1 This method is applicable to the determination of Destruction and Removal Efficiency (DRE) of semivolatile Principal Organic Hazardous Compounds (POHCs) from incineration systems (PHS, 1967). This method also may be used to determine particulate emission rates from stationary sources as per EPA Method 5 (see References at end of this method).

2.0 SUMMARY OF METHOD

2.1 Gaseous and particulate pollutants are withdrawn from an emission source at an isokinetic sampling rate and are collected in a multicomponent sampling train. Principal components of the train include a high-efficiency glass- or quartz-fiber filter and a packed bed of porous polymeric adsorbent resin. The filter is used to collect organic-laden particulate materials and the porous polymeric resin to adsorb semivolatile organic species. Semivolatile species are defined as compounds with boiling points >100°C.

2.2 Comprehensive chemical analyses of the collected sample are conducted to determine the concentration and identity of the organic materials.

3.0 INTERFERENCES

3.1 Oxides of nitrogen (NO_x) are possible interferents in the determination of certain water-soluble compounds such as dioxane, phenol, and urethane; reaction of these compounds with NO_x in the presence of moisture will reduce their concentration. Other possibilities that could result in positive or negative bias are (1) stability of the compounds in methylene chloride, (2) the formation of water-soluble organic salts on the resin in the presence of moisture, and (3) the solvent extraction efficiency of water-soluble compounds from aqueous media. Use of two or more ions per compound for qualitative and quantitative analysis can overcome interference at one mass. These concerns should be addressed on a compound-by-compound basis before using this method.

4.0 APPARATUS AND MATERIALS

4.1 Sampling train:

4.1.1 A schematic of the sampling train used in this method is shown in Figure 1. This sampling train configuration is adapted from EPA Method 5 procedures, and, as such, the majority of the required equipment

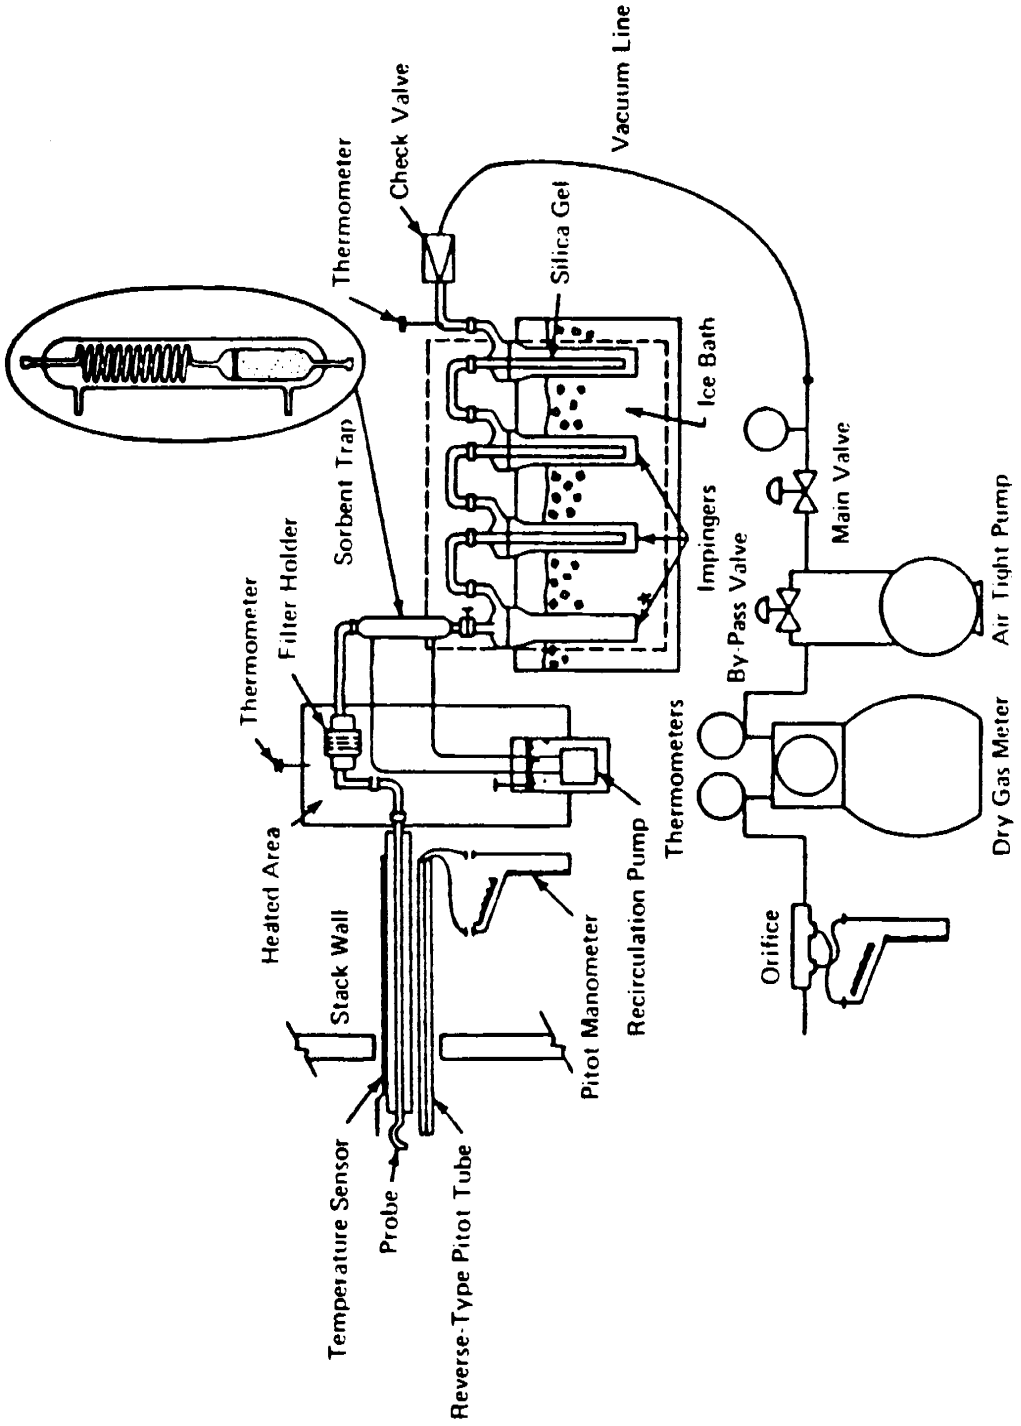

Figure 1. Modified Method 5 Sampling Train.

is identical to that used in EPA Method 5 determinations. The new components required are a condenser coil and a sorbent module, which are used to collect semivolatile organic materials that pass through the glass- or quartz-fiber filter in the gas phase.

4.1.2 Construction details for the basic train components are given in APTD-0581 (see Martin, 1971, in Section 13.0, References); commercial models of this equipment are also available. Specifications for the sorbent module are provided in the following subsections. Additionally, the following subsections list changes to APTD-0581 and identify allowable train configuration modifications.

4.1.3 Basic operating and maintenance procedures for the sampling train are described in APTD-0576 (see Rom, 1972, in Section 13.0, References). As correct usage is important in obtaining valid results, all users should refer to APTD-0576 and adopt the operating and maintenance procedures outlined therein unless otherwise specified. The sampling train consists of the components detailed below.

4.1.3.1 Probe nozzle: Stainless steel (316) or glass with sharp, tapered (30° angle) leading edge. The taper shall be on the outside to preserve a constant I.D. The nozzle shall be buttonhook or elbow design and constructed from seamless tubing (if made of stainless steel). Other construction materials may be considered for particular applications. A range of nozzle sizes suitable for isokinetic sampling should be available in increments of 0.16 cm (1/16 in.), e.g., 0.32-1.27 cm (1/8-1/2 in.), or larger if higher volume sampling trains are used. Each nozzle shall be calibrated according to the procedures outlined in Paragraph 9.1.

4.1.3.2 Probe liner: Borosilicate or quartz-glass tubing with a heating system capable of maintaining a gas temperature of 120 $\pm$ 14°C (248 $\pm$ 25°F) at the exit end during sampling. (The tester may opt to operate the equipment at a temperature lower than that specified.) Because the actual temperature at the outlet of the probe is not usually monitored during sampling, probes constructed according to APTD-0581 and utilizing the calibration curves of APTD-0576 (or calibrated according to the procedure outlined in APTD-0576) are considered acceptable. Either borosilicate or quartz-glass probe liners may be used for stack temperatures up to about 480°C (900°F). Quartz liners shall be used for temperatures between 480 and 900°C (900 and 1650°F). (The softening temperature for borosilicate is 820°C (1508°F), and for quartz 1500°C (2732°F).) Water-cooling of the stainless steel sheath will be necessary at temperatures approaching and exceeding 500°C.

4.1.3.3 Pitot tube: Type S, as described in Section 2.1 of EPA Method 2, or other appropriate devices (Vollaro, 1976). The pitot tube shall be attached to the probe to allow constant monitoring of the stack-gas velocity. The impact (high-pressure) opening plane of the pitot tube shall be even with or above the nozzle entry plane (see EPA Method 2, Figure 2-6b) during sampling. The Type S pitot tube assembly shall have a known coefficient, determined as outlined in Section 4 of EPA Method 2.

4.1.3.4 Differential pressure gauge: Inclined manometer or equivalent device as described in Section 2.2 of EPA Method 2. One manometer shall be used for velocity-head (ΔP) readings and the other for orifice differential pressure (ΔH) readings.

4.1.3.5 Filter holder: Borosilicate glass, with a glass frit filter support and a sealing gasket. The sealing gasket should be made of materials that will not introduce organic material into the gas stream at the temperature at which the filter holder will be maintained. The gasket shall be constructed of Teflon or materials of equal or better characteristics. The holder design shall provide a positive seal against leakage at any point along the filter circumference. The holder shall be attached immediately to the outlet of the cyclone or cyclone bypass.

4.1.3.6 Filter heating system: Any heating system capable of maintaining a temperature of 120 $\pm$ 14°C (248 $\pm$ 25°F) around the filter holder during sampling. Other temperatures may be appropriate for particular applications. Alternatively, the tester may opt to operate the equipment at temperatures other than that specified. A temperature gauge capable of measuring temperature to within 3°C (5.4°F) shall be installed so that the temperature around the filter holder can be regulated and monitored during sampling. Heating systems other than the one shown in APTD-0581 may be used.

4.1.3.7 Organic sampling module: This unit consists of three sections, including a gas-conditioning section, a sorbent trap, and a condensate knockout trap. The gas-conditioning system shall be capable of conditioning the gas leaving the back half of the filter holder to a temperature not exceeding 20°C (68°F). The sorbent trap shall be sized to contain approximately 20 g of porous polymeric resin (Rohm and Haas XAD-2 or equivalent) and shall be jacketed to maintain the internal gas temperature at 17 $\pm$ 3°C (62.5 $\pm$ 5.4°F). The most commonly used coolant is ice water from the impinger ice-water bath, constantly circulated through the outer jacket, using rubber or plastic tubing and a peristaltic pump. The sorbent trap should be outfitted with a glass well or depression, appropriately sized to accommodate a small thermocouple in the trap for monitoring the gas entry temperature. The condensate knockout trap shall be of sufficient size to collect the condensate following gas conditioning. The organic module components shall be oriented to direct the flow of condensate formed vertically downward from the conditioning section, through the adsorbent media, and into the condensate knockout trap. The knockout trap is usually similar in appearance to an empty impinger directly underneath the sorbent module; it may be oversized but should have a shortened center stem (at a minimum, one-half the length of the normal impinger stems) to collect a large volume of condensate without bubbling and overflowing into the impinger train. All surfaces of the organic module wetted by the gas sample shall be fabricated of borosilicate glass, Teflon, or other inert materials. Commercial versions of the

complete organic module are not currently available, but may be assembled from commercially available laboratory glassware and a custom-fabricated sorbent trap. Details of two acceptable designs are shown in Figures 2 and 3 (the thermocouple well is shown in Figure 2).

4.1.3.8 Impinger train: To determine the stack-gas moisture content, four 500-mL impingers, connected in series with leak-free ground-glass joints, follow the knockout trap. The first, third, and fourth impingers shall be of the Greenburg-Smith design, modified by replacing the tip with a 1.3-cm (1/2-in.) I.D. glass tube extending about 1.3 cm (1/2 in.) from the bottom of the outer cylinder. The second impinger shall be of the Greenburg-Smith design with the standard tip. The first and second impingers shall contain known quantities of water or appropriate trapping solution. The third shall be empty or charged with a caustic solution, should the stack gas contain hydrochloric acid (HCl). The fourth shall contain a known weight of silica gel or equivalent desiccant.

4.1.3.9 Metering system: The necessary components are a vacuum gauge, leak-free pump, thermometers capable of measuring temperature to within 3°C (5.4°F), dry-gas meter capable of measuring volume to within 1%, and related equipment, as shown in Figure 1. At a minimum, the pump should be capable of 4 cfm free flow, and the dry-gas meter should have a recording capacity of 0-999.9 cu ft with a resolution of 0.005 cu ft. Other metering systems capable of maintaining sampling rates within 10% of isokineticity and of determining sample volumes to within 2% may be used. The metering system must be used in conjunction with a pitot tube to enable checks of isokinetic sampling rates. Sampling trains using metering systems designed for flow rates higher than those described in APTD-0581 and APTD-0576 may be used, provided that the specifications of this method are met.

4.1.3.10 Barometer: Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases the barometric reading may be obtained from a nearby National Weather Service station, in which case the station value (which is the absolute barometric pressure) is requested and an adjustment for elevation differences between the weather station and sampling point is applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30-m (100 ft) elevation increase (vice versa for elevation decrease).

4.1.3.11 Gas density determination equipment: Temperature sensor and pressure gauge (as described in Sections 2.3 and 2.4 of EPA Method 2), and gas analyzer, if necessary (as described in EPA Method 3). The temperature sensor ideally should be permanently attached to the pitot tube or sampling probe in a fixed configuration such that the tip of the sensor extends beyond the leading edge of the probe sheath and does not touch any metal.

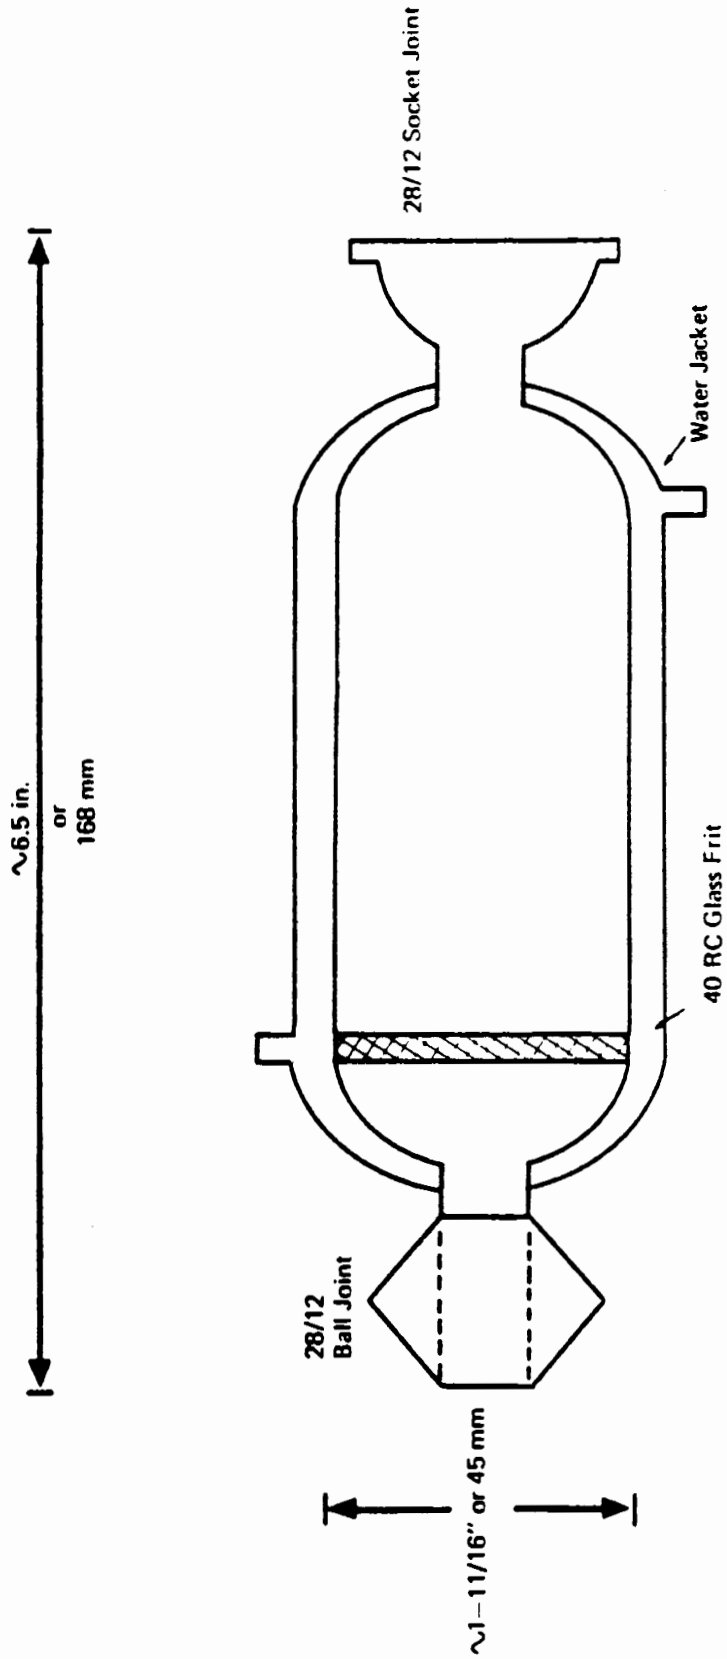

Figure 2. Adsorbent Sampling System.

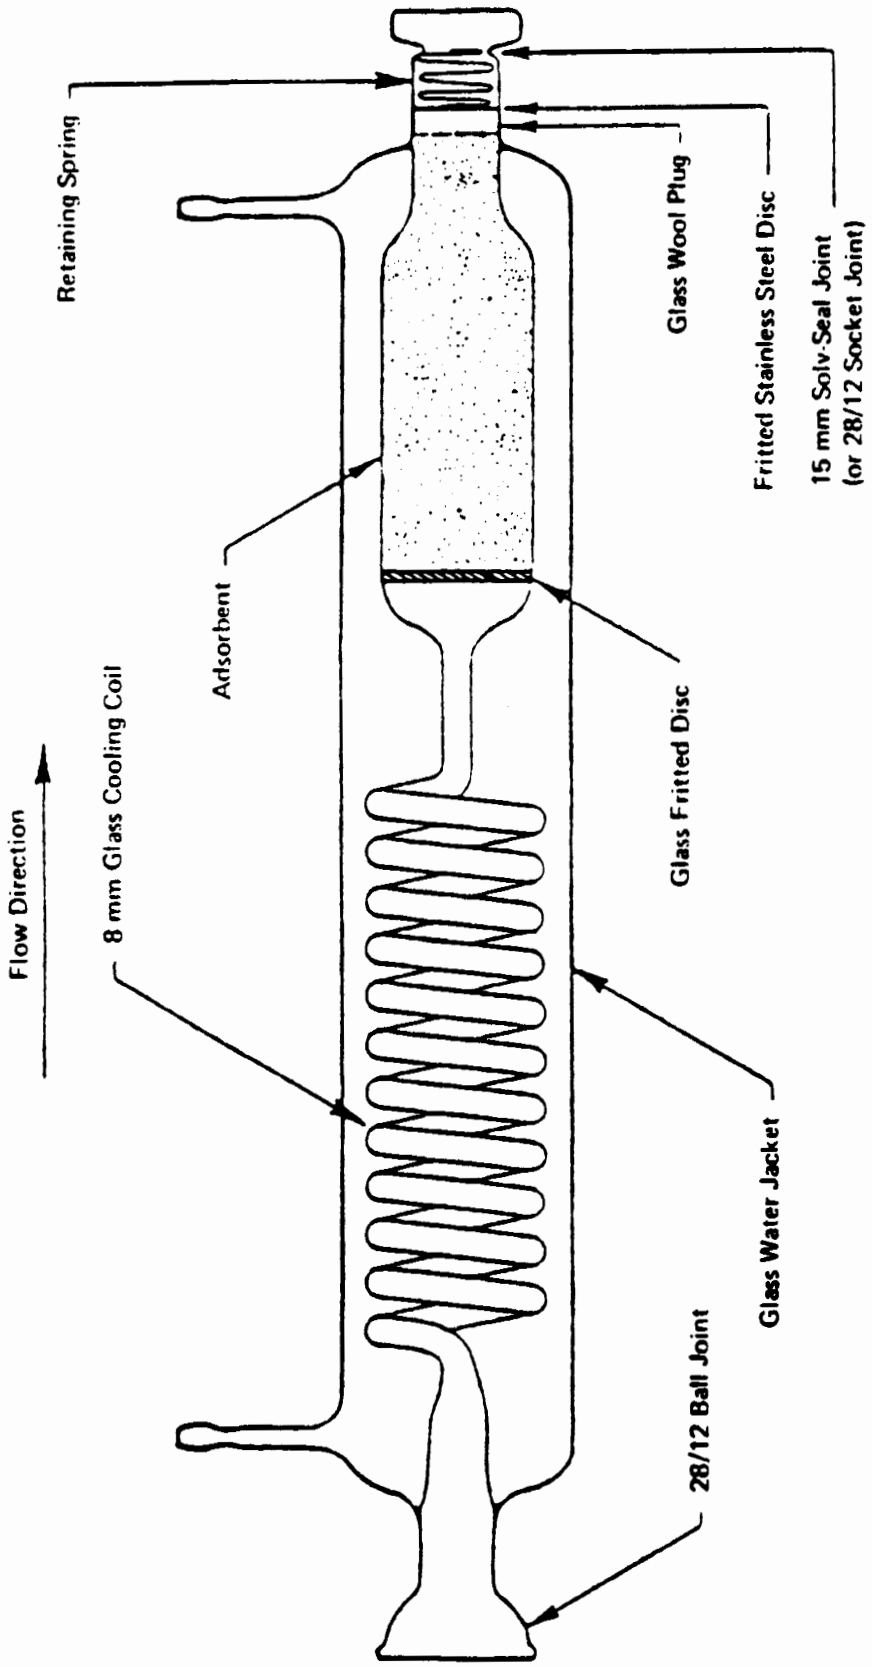

Figure 3. Adsorbent Sampling System.

Alternatively, the sensor may be attached just prior to use in the field. Note, however, that if the temperature sensor is attached in the field, the sensor must be placed in an interference-free arrangement with respect to the Type S pitot tube openings (see EPA Method 2, Figure 2-7). As a second alternative, if a difference of no more than 1% in the average velocity measurement is to be introduced, the temperature gauge need not be attached to the probe or pitot tube.

4.1.3.12 Calibration/field-preparation record: A permanently bound laboratory notebook, in which duplicate copies of data may be made as they are being recorded, is required for documenting and recording calibrations and preparation procedures (i.e., filter and silica gel tare weights, clean XAD-2, quality assurance/quality control check results, dry-gas meter, and thermocouple calibrations, etc.). The duplicate copies should be detachable and should be stored separately in the test program archives.

4.2 Sample Recovery:

4.2.1 **Probe liner:** Probe nozzle and organic module conditioning section brushes; nylon bristle brushes with stainless steel wire handles are required. The probe brush shall have extensions of stainless steel, Teflon, or inert material at least as long as the probe. The brushes shall be properly sized and shaped to brush out the probe liner, the probe nozzle, and the organic module conditioning section.

4.2.2 **Wash bottles:** Three. Teflon or glass wash bottles are recommended; polyethylene wash bottles should not be used because organic contaminants may be extracted by exposure to organic solvents used for sample recovery.

4.2.3 **Glass sample storage containers:** Chemically resistant, borosilicate amber and clear glass bottles, 500-mL or 1,000-mL. Bottles should be tinted to prevent action of light on sample. Screw-cap liners shall be either Teflon or constructed so as to be leak-free and resistant to chemical attack by organic recovery solvents. Narrow-mouth glass bottles have been found to exhibit less tendency toward leakage.

4.2.4 **Petri dishes:** Glass, sealed around the circumference with wide (1-in.) Teflon tape, for storage and transport of filter samples.

4.2.5 **Graduated cylinder and/or balances:** To measure condensed water to the nearest 1 mL or 1 g. Graduated cylinders shall have subdivisions not >2 mL. Laboratory triple-beam balances capable of weighing to $\pm$0.5 g or better are required.

4.2.6 **Plastic storage containers:** Screw-cap polypropylene or polyethylene containers to store silica gel.

4.2.7 **Funnel and rubber policeman:** To aid in transfer of silica gel to container (not necessary if silica gel is weighed in field).

4.2.8 **Funnels:** Glass, to aid in sample recovery.

4.3 Filters: Glass- or quartz-fiber filters, without organic binder, exhibiting at least 99.95% efficiency (<0.05% penetration) on 0.3-um dioctyl phthalate smoke particles. The filter efficiency test shall be conducted in accordance with ASTM standard method D2986-71. Test data from the supplier's quality control program are sufficient for this purpose. In sources containing SO_2 or SO_3, the filter material must be of a type that is unreactive to SO_2 or SO_3. Reeve Angel 934 AH or Schleicher and Schwell #3 filters work well under these conditions.

4.4 Crushed ice: Quantities ranging from 10-50 lb may be necessary during a sampling run, depending on ambient air temperature.

4.5 Stopcock grease: Solvent-insoluble, heat-stable silicone grease. Use of silicone grease upstream of the module is not permitted, and amounts used on components located downstream of the organic module shall be minimized. Silicone grease usage is not necessary if screw-on connectors and Teflon sleeves or ground-glass joints are used.

4.6 Glass wool: Used to plug the unfritted end of the sorbent module. The glass-wool fiber should be solvent-extracted with methylene chloride in a Soxhlet extractor for 12 hr and air-dried prior to use.

5.0 REAGENTS

5.1 Adsorbent resin: Porous polymeric resin (XAD-2 or equivalent) is recommended. These resins shall be cleaned prior to their use for sample collection. Appendix A of this method should be consulted to determine appropriate precleaning procedure. For best results, resin used should not exhibit a blank of higher than 4 mg/kg of total chromatographable organics (TCO) (see Appendix B) prior to use. Once cleaned, resin should be stored in an airtight, wide-mouth amber glass container with a Teflon-lined cap or placed in one of the glass sorbent modules tightly sealed with Teflon film and elastic bands. The resin should be used within 4 wk of the preparation.

5.2 Silica gel: Indicating type, 6-16 mesh. If previously used, dry at 175°C (350°F) for 2 hr before using. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used, subject to the approval of the Administrator.

5.3 Impinger solutions: Distilled organic-free water (Type II) shall be used, unless sampling is intended to quantify a particular inorganic gaseous species. If sampling is intended to quantify the concentration of additional species, the impinger solution of choice shall be subject to Administrator approval. This water should be prescreened for any compounds of interest. One hundred mL will be added to the specified impinger; the third impinger in the train may be charged with a basic solution (1 N sodium hydroxide or sodium acetate) to protect the sampling pump from acidic gases. Sodium acetate should be used when large sample volumes are anticipated because sodium hydroxide will react with carbon dioxide in aqueous media to form sodium carbonate, which may possibly plug the impinger.

5.4 Sample recovery reagents:

5.4.1 **Methylene chloride:** Distilled-in-glass grade is required for sample recovery and cleanup (see Note to 5.4.2 below).

5.4.2 **Methyl alcohol:** Distilled-in-glass grade is required for sample recovery and cleanup.

NOTE: Organic solvents from metal containers may have a high residue blank and should not be used. Sometimes suppliers transfer solvents from metal to glass bottles; thus blanks shall be run prior to field use and only solvents with low blank value (<0.001%) shall be used.

5.4.3 **Water:** Water (Type II) shall be used for rinsing the organic module and condenser component.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Because of complexity of this method, field personnel should be trained in and experienced with the test procedures in order to obtain reliable results.

6.2 Laboratory preparation:

6.2.1 All the components shall be maintained and calibrated according to the procedure described in APTD-0576, unless otherwise specified.

6.2.2 Weigh several 200- to 300-g portions of silica gel in airtight containers to the nearest 0.5 g. Record on each container the total weight of the silica gel plus containers. As an alternative to preweighing the silica gel, it may instead be weighed directly in the impinger or sampling holder just prior to train assembly.

6.2.3 Check filters visually against light for irregularities and flaws or pinhole leaks. Label the shipping containers (glass Petri dishes) and keep the filters in these containers at all times except during sampling and weighing.

6.2.4 Desiccate the filters at 20 ± 5.6°C (68 ± 10°F) and ambient pressure for at least 24 hr, and weigh at intervals of at least 6 hr to a constant weight (i.e., <0.5-mg change from previous weighing), recording results to the nearest 0.1 mg. During each weighing the filter must not be exposed for more than a 2-min period to the laboratory atmosphere and relative humidity above 50%. Alternatively (unless otherwise specified by the Administrator), the filters may be oven-dried at 105°C (220°F) for 2-3 hr, desiccated for 2 hr, and weighed.

6.3 Preliminary field determinations:

6.3.1 Select the sampling site and the minimum number of sampling points according to EPA Method 1 or as specified by the Administrator. Determine the stack pressure, temperature, and range of velocity heads using EPA Method 2. It is recommended that a leak-check of the pitot lines (see EPA Method 2, Section 3.1) be performed. Determine the stack-gas moisture content using EPA Approximation Method 4 or its alternatives to establish estimates of isokinetic sampling-rate settings. Determine the stack-gas dry molecular weight, as described in EPA Method 2, Section 3.6. If integrated EPA Method 3 sampling is used for molecular weight determination, the integrated bag sample shall be taken simultaneously with, and for the same total length of time as, the sample run.

6.3.2 Select a nozzle size based on the range of velocity heads so that it is not necessary to change the nozzle size in order to maintain isokinetic sampling rates. During the run, do not change the nozzle. Ensure that the proper differential pressure gauge is chosen for the range of velocity heads encountered (see Section 2.2 of EPA Method 2).

6.3.3 Select a suitable probe liner and probe length so that all traverse points can be sampled. For large stacks, to reduce the length of the probe, consider sampling from opposite sides of the stack.

6.3.4 A minimum of 3 dscm (105.9 dscf) of sample volume is required for the determination of the Destruction and Removal Efficiency (DRE) of POHCs from incineration systems. Additional sample volume shall be collected as necessitated by analytical detection limit constraints. To determine the minimum sample volume required, refer to sample calculations in Section 10.0.

6.3.5 Determine the total length of sampling time needed to obtain the identified minimum volume by comparing the anticipated average sampling rate with the volume requirement. Allocate the same time to all traverse points defined by EPA Method 1. To avoid timekeeping errors, the length of time sampled at each traverse point should be an integer or an integer plus one-half min.

6.3.6 In some circumstances (e.g., batch cycles) it may be necessary to sample for shorter times at the traverse points and to obtain smaller gas-sample volumes. In these cases, the Administrator's approval must first be obtained.

6.4 Preparation of collection train:

6.4.1 During preparation and assembly of the sampling train, keep all openings where contamination can occur covered with Teflon film or aluminum foil until just prior to assembly or until sampling is about to begin.

6.4.2 Fill the sorbent trap section of the organic module with approximately 20 g of clean adsorbent resin. While filling, ensure that the trap packs uniformly, to eliminate the possibility of channeling. When freshly cleaned, many adsorbent resins carry a static charge, which will cause clinging to trap walls. This may be minimized by filling the trap in the presence of an antistatic device. Commercial antistatic devices include Model-204 and Model-210 manufactured by the 3M Company, St. Paul, Minnesota.

6.4.3 If an impinger train is used to collect moisture, place 100 mL of water in each of the first two impingers, leave the third impinger empty (or charge with caustic solution, as necessary), and transfer approximately 200-300 g of preweighed silica gel from its container to the fourth impinger. More silica gel may be used, but care should be taken to ensure that it is not entrained and carried out from the impinger during sampling. Place the container in a clean place for later use in the sample recovery. Alternatively, the weight of the silica gel plus impinger may be determined to the nearest 0.5 g and recorded.

6.4.4 Using a tweezer or clean disposable surgical gloves, place a labeled (identified) and weighed filter in the filter holder. Be sure that the filter is properly centered and the gasket properly placed to prevent the sample gas stream from circumventing the filter. Check the filter for tears after assembly is completed.

6.4.5 When glass liners are used, install the selected nozzle using a Viton-A O-ring when stack temperatures are <260°C (500°F) and a woven glass-fiber gasket when temperatures are higher. See APTD-0576 (Rom, 1972) for details. Other connecting systems utilizing either 316 stainless steel or Teflon ferrules may be used. When metal liners are used, install the nozzle as above, or by a leak-free direct mechanical connection. Mark the probe with heat-resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point.

6.4.6 Set up the train as in Figure 1. During assembly, do not use any silicone grease on ground-glass joints that are located upstream of the organic module. A very light coating of silicone grease may be used on all ground-glass joints that are located downstream of the organic module, but it should be limited to the outer portion (see APTD-0576) of the ground-glass joints to minimize silicone-grease contamination. Subject to the approval of the Administrator, a glass cyclone may be used between the probe and the filter holder when the total particulate catch is expected to exceed 100 mg or when water droplets are present in the stack. The organic module condenser must be maintained at a temperature of 17 $\pm$ 3°C. Connect all temperature sensors to an appropriate potentiometer/display unit. Check all temperature sensors at ambient temperature.

6.4.7 Place crushed ice around the impingers and the organic module condensate knockout.

6.4.8 Turn on the sorbent module and condenser coil coolant recirculating pump and begin monitoring the sorbent module gas entry temperature. Ensure proper sorbent module gas entry temperature before proceeding and again before any sampling is initiated. It is extremely important that the XAD-2 resin temperature never exceed 50°C (122°F), because thermal decomposition will occur. During testing, the XAD-2 temperature must not exceed 20°C (68°F) for efficient capture of the semivolatile species of interest.

6.4.9 Turn on and set the filter and probe heating systems at the desired operating temperatures. Allow time for the temperatures to stabilize.

6.5 Leak-check procedures

6.5.1 **Pre-test leak-check:**

6.5.1.1 Because the number of additional intercomponent connections in the Semi-VOST train (over the M5 Train) increases the possibility of leakage, a pre-test leak-check is required.

6.5.1.2 After the sampling train has been assembled, turn on and set the filter and probe heating systems at the desired operating temperatures. Allow time for the temperatures to stabilize. If a Viton A O-ring or other leak-free connection is used in assembling the probe nozzle to the probe liner, leak-check the train at the sampling site by plugging the nozzle and pulling a 381-mm Hg (15-in. Hg) vacuum.
(NOTE: A lower vacuum may be used, provided that it is not exceeded during the test.)

6.5.1.3 If an asbestos string is used, do not connect the probe to the train during the leak-check. Instead, leak-check the train by first attaching a carbon-filled leak-check impinger (shown in Figure 4) to the inlet of the filter holder (cyclone, if applicable) and then plugging the inlet and pulling a 381-mm Hg (15-in. Hg) vacuum. (Again, a lower vacuum may be used, provided that it is not exceeded during the test.) Then, connect the probe to the train and leak-check at about 25-mm Hg (1-in. Hg) vacuum; alternatively, leak-check the probe with the rest of the sampling train in one step at 381-mm Hg (15-in. Hg) vacuum. Leakage rates in excess of 4% of the average sampling rate or >0.00057 m^3/min (0.02 cfm), whichever is less, are unacceptable.

6.5.1.4 The following leak-check instructions for the sampling train described in APTD-0576 and APTD-0581 may be helpful. Start the pump with fine-adjust valve fully open and coarse-adjust valve completely closed. Partially open the coarse-adjust valve and slowly close the fine-adjust valve until the desired vacuum is reached. Do not reverse direction of the fine-adjust valve; this will cause water to back up into the organic module. If the desired vacuum is exceeded, either leak-check at this higher vacuum or end the leak-check, as shown below, and start over.

CROSS SECTIONAL VIEW

Leak Testing Apparatus

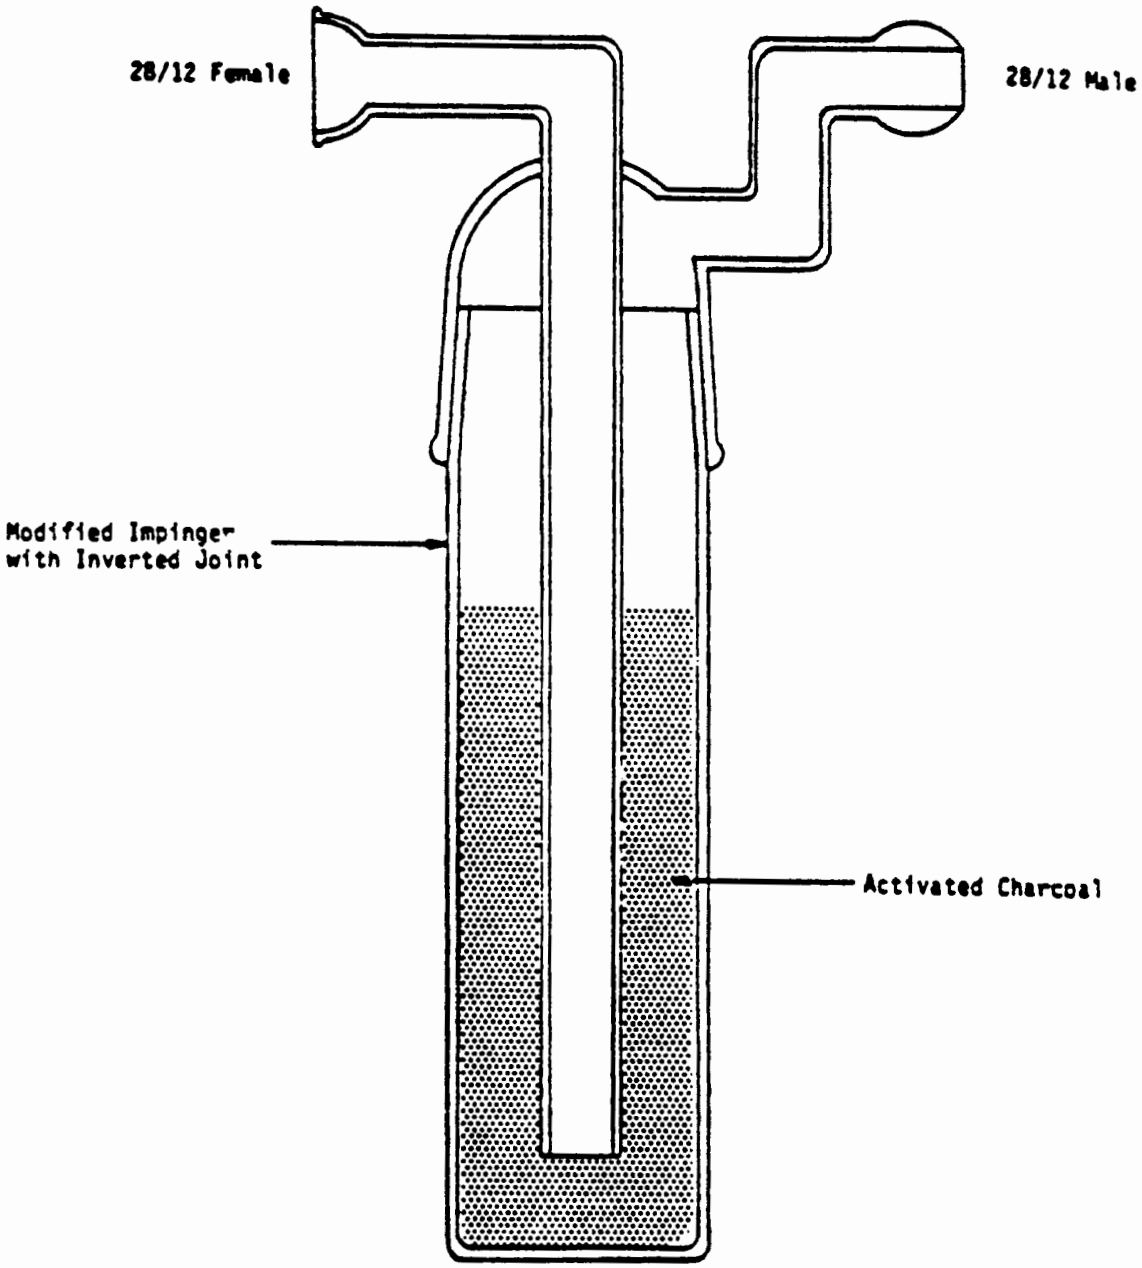

Figure 4. Leak-check Impinger

6.5.1.5 When the leak-check is completed, first slowly remove the plug from the inlet to the probe, filter holder, or cyclone (if applicable). When the vacuum drops to 127 mm (5 in.) Hg or less, immediately close the coarse-adjust valve. Switch off the pumping system and reopen the fine-adjust valve. Do not reopen the fine-adjust valve until the coarse-adjust valve has been closed. This prevents the water in the impingers from being forced backward into the organic module and silica gel from being entrained backward into the third impinger.

6.5.2 **Leak-checks during sampling run:**

6.5.2.1 If, during the sampling run, a component (e.g., filter assembly, impinger, or sorbent trap) change becomes necessary, a leak-check shall be conducted immediately after the interruption of sampling and before the change is made. The leak-check shall be done according to the procedure outlined in Paragraph 6.5.1, except that it shall be done at a vacuum greater than or equal to the maximum value recorded up to that point in the test. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable, and no correction will need to be applied to the total volume of dry gas metered. If a higher leakage rate is obtained, the tester shall void the sampling run. (It should be noted that any "correction" of the sample volume by calculation by calculation reduces the integrity of the pollutant concentrations data generated and must be avoided.)

6.5.2.2 Immediately after a component change, and before sampling is reinitiated, a leak-check similar to a pre-test leak-check must also be conducted.

6.5.3 **Post-test leak-check:**

6.5.3.1 A leak-check is mandatory at the conclusion of each sampling run. The leak-check shall be done with the same procedures as those with the pre-test leak-check, except that it shall be conducted at a vacuum greater than or equal to the maximum value reached during the sampling run. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable, and no correction need be applied to the total volume of dry gas metered. If, however, a higher leakage rate is obtained, the tester shall either record the leakage rate, correct the sample volume (as shown in the calculation section of this method), and consider the data obtained of questionable reliability, or void the sampling run.

6.6 Sampling-train operation:

6.6.1 During the sampling run, maintain an isokinetic sampling rate to within 10% of true isokinetic, unless otherwise specified by the Administrator. Maintain a temperature around the filter of 120 ± 14°C (248 ± 25°F) and a gas temperature entering the sorbent trap at a maximum of 20°C (68°F).

6.6.2 For each run, record the data required on a data sheet such as the one shown in Figure 5. Be sure to record the initial dry-gas meter reading. Record the dry-gas meter readings at the beginning and end of each sampling time increment, when changes in flow rates are made before and after each leak-check, and when sampling is halted. Take other readings required by Figure 5 at least once at each sample point during each time increment and additional readings when significant changes (20% variation in velocity-head readings) necessitate additional adjustments in flow rate. Level and zero the manometer. Because the manometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse.

6.6.3 Clean the stack access ports prior to the test run to eliminate the chance of sampling deposited material. To begin sampling, remove the nozzle cap, verify that the filter and probe heating systems are at the specified temperature, and verify that the pitot tube and probe are properly positioned. Position the nozzle at the first traverse point, with the tip pointing directly into the gas stream. Immediately start the pump and adjust the flow to isokinetic conditions. Nomographs, which aid in the rapid adjustment of the isokinetic sampling rate without excessive computations, are available. These nomographs are designed for use when the Type S pitot-tube coefficient is 0.84 $\pm$ 0.02 and the stack-gas equivalent density (dry molecular weight) is equal to 29 $\pm$ 4. APTD-0576 details the procedure for using the nomographs. If the stack-gas molecular weight and the pitot-tube coefficient are outside the above ranges, do not use the nomographs unless appropriate steps (Shigehara, 1974) are taken to compensate for the deviations.

6.6.4 When the stack is under significant negative pressure (equivalent to the height of the impinger stem), take care to close the coarse-adjust valve before inserting the probe into the stack, to prevent water from backing into the organic module. If necessary, the pump may be turned on with the coarse-adjust valve closed.

6.6.5 When the probe is in position, block off the openings around the probe and stack access port to prevent unrepresentative dilution of the gas stream.

6.6.6 Traverse the stack cross section, as required by EPA Method 1 or as specified by the Administrator, being careful not to bump the probe nozzle into the stack walls when sampling near the walls or when removing or inserting the probe through the access port, in order to minimize the chance of extracting deposited material.

6.6.7 During the test run, make periodic adjustments to keep the temperature around the filter holder and the organic module at the proper levels; add more ice and, if necessary, salt to maintain a temperature of <20°C (68°F) at the condenser/silica gel outlet. Also, periodically check the level and zero of the manometer.

Figure 5. Particulate field data.

Revision 0
Date September 1986

6.6.8 If the pressure drop across the filter or sorbent trap becomes too high, making isokinetic sampling difficult to maintain, the filter/sorbent trap may be replaced in the midst of a sample run. Using another complete filter holder/sorbent trap assembly is recommended, rather than attempting to change the filter and resin themselves. After a new filter/sorbent trap assembly is installed, conduct a leak-check. The total particulate weight shall include the summation of all filter assembly catches.

6.6.9 A single train shall be used for the entire sample run, except in cases where simultaneous sampling is required in two or more separate ducts or at two or more different locations within the same duct, or in cases where equipment failure necessitates a change of trains. In all other situations, the use of two or more trains will be subject to the approval of the Administrator.

6.6.10 Note that when two or more trains are used, separate analysis of the front-half (if applicable) organic-module and impinger (if applicable) catches from each train shall be performed, unless identical nozzle sizes were used on all trains. In that case, the front-half catches from the individual trains may be combined (as may the impinger catches), and one analysis of front-half catch and one analysis of impinger catch may be performed.

6.6.11 At the end of the sample run, turn off the coarse-adjust valve, remove the probe and nozzle from the stack, turn off the pump, record the final dry-gas meter reading, and conduct a post-test leak-check. Also, leak-check the pitot lines as described in EPA Method 2. The lines must pass this leak-check in order to validate the velocity-head data.

6.6.12 Calculate percent isokineticity (see Section 10.8) to determine whether the run was valid or another test run should be made.

7.0 SAMPLE RECOVERY

7.1 Preparation:

7.1.1 Proper cleanup procedure begins as soon as the probe is removed from the stack at the end of the sampling period. Allow the probe to cool. When the probe can be safely handled, wipe off all external particulate matter near the tip of the probe nozzle and place a cap over the tip to prevent losing or gaining particulate matter. Do not cap the probe tip tightly while the sampling train is cooling down because this will create a vacuum in the filter holder, drawing water from the impingers into the sorbent module.

7.1.2 Before moving the sample train to the cleanup site, remove the probe from the sample train and cap the open outlet, being careful not to lose any condensate that might be present. Cap the filter inlet.

Remove the umbilical cord from the last impinger and cap the impinger. If a flexible line is used between the organic module and the filter holder, disconnect the line at the filter holder and let any condensed water or liquid drain into the organic module.

7.1.3 Cap the filter-holder outlet and the inlet to the organic module. Separate the sorbent trap section of the organic module from the condensate knockout trap and the gas-conditioning section. Cap all organic module openings. Disconnect the organic-module knockout trap from the impinger train inlet and cap both of these openings. Ground-glass stoppers, Teflon caps, or caps of other inert materials may be used to seal all openings.

7.1.4 Transfer the probe, the filter, the organic-module components, and the impinger/condenser assembly to the cleanup area. This area should be clean and protected from the weather to minimize sample contamination or loss.

7.1.5 Save a portion of all washing solutions (methanol/methylene chloride, Type II water) used for cleanup as a blank. Transfer 200 mL of each solution directly from the wash bottle being used and place each in a separate, prelabeled glass sample container.

7.1.6 Inspect the train prior to and during disassembly and note any abnormal conditions.

7.2 Sample containers:

7.2.1 **Container no. 1:** Carefully remove the filter from the filter holder and place it in its identified Petri dish container. Use a pair or pairs of tweezers to handle the filter. If it is necessary to fold the filter, ensure that the particulate cake is inside the fold. Carefully transfer to the Petri dish any particulate matter or filter fibers that adhere to the filter-holder gasket, using a dry nylon bristle brush or sharp-edged blade, or both. Label the container and seal with 1-in.-wide Teflon tape around the circumference of the lid.

7.2.2 **Container no. 2:** Taking care that dust on the outside of the probe or other exterior surfaces does not get into the sample, quantitatively recover particulate matter or any condensate from the probe nozzle, probe fitting, probe liner, and front half of the filter holder by washing these components first with methanol/methylene chloride (1:1 v/v) into a glass container. Distilled water may also be used. Retain a water and solvent blank and analyze in the same manner as with the samples. Perform rinses as follows:

7.2.2.1 Carefully remove the probe nozzle and clean the inside surface by rinsing with the solvent mixture (1:1 v/v methanol/-methylene chloride) from a wash bottle and brushing with a nylon bristle brush. Brush until the rinse shows no visible particles; then make a final rinse of the inside surface with the solvent mix. Brush and rinse the inside parts of the Swagelok fitting with the solvent mix in a similar way until no visible particles remain.

7.2.2.2 Have two people rinse the probe liner with the solvent mix by tilting and rotating the probe while squirting solvent into its upper end so that all inside surfaces will be wetted with solvent. Let the solvent drain from the lower end into the sample container. A glass funnel may be used to aid in transferring liquid washes to the container.

7.2.2.3 Follow the solvent rinse with a probe brush. Hold the probe in an inclined position and squirt solvent into the upper end while pushing the probe brush through the probe with a twisting action; place a sample container underneath the lower end of the probe and catch any solvent and particulate matter that is brushed from the probe. Run the brush through the probe three times or more until no visible particulate matter is carried out with the solvent or until none remains in the probe liner on visual inspection. With stainless steel or other metal probes, run the brush through in the above-prescribed manner at least six times (metal probes have small crevices in which particulate matter can be entrapped). Rinse the brush with solvent and quantitatively collect these washings in the sample container. After the brushing, make a final solvent rinse of the probe as described above.

7.2.2.4 It is recommended that two people work together to clean the probe to minimize sample losses. Between sampling runs, keep brushes clean and protected from contamination.

7.2.2.5 Clean the inside of the front half of the filter holder and cyclone/cyclone flask, if used, by rubbing the surfaces with a nylon bristle brush and rinsing with methanol/methylene chloride (1:1 v/v) mixture. Rinse each surface three times or more if needed to remove visible particulate. Make a final rinse of the brush and filter holder. Carefully rinse out the glass cyclone and cyclone flask (if applicable). Brush and rinse any particulate material adhering to the inner surfaces of these components into the front-half rinse sample. After all solvent washings and particulate matter have been collected in the sample container, tighten the lid on the sample container so that solvent will not leak out when it is shipped to the laboratory. Mark the height of the fluid level to determine whether leakage occurs during transport. Label the container to identify its contents.

7.2.3 **Container no. 3:** The sorbent trap section of the organic module may be used as a sample transport container, or the spent resin may be transferred to a separate glass bottle for shipment. If the sorbent trap itself is used as the transport container, both ends should be sealed with tightly fitting caps or plugs. Ground-glass stoppers or Teflon caps may be used. The sorbent trap should then be labeled, covered with aluminum foil, and packaged on ice for transport to the laboratory. If a separate bottle is used, the spent resin should be quantitatively transferred from the trap into the clean bottle. Resin that adheres to the walls of the trap should be recovered using a rubber policeman or spatula and added to this bottle.

7.2.4 **Container no. 4:** Measure the volume of condensate collected in the condensate knockout section of the organic module to within ±1 mL by using a graduated cylinder or by weighing to within ±0.5 g using a triple-beam balance. Record the volume or weight of liquid present and note any discoloration or film in the liquid catch. Transfer this liquid to a prelabeled glass sample container. Inspect the back half of the filter housing and the gas-conditioning section of the organic module. If condensate is observed, transfer it to a graduated or weighing bottle and measure the volume, as described above. Add this material to the condensate knockout-trap catch.

7.2.5 **Container no. 5:** All sampling train components located between the high-efficiency glass- or quartz-fiber filter and the first wet impinger or the final condenser system (including the heated Teflon line connecting the filter outlet to the condenser) should be thoroughly rinsed with methanol/methylene chloride (1:1 v/v) and the rinsings combined. This rinse shall be separated from the condensate. If the spent resin is transferred from the sorbent trap to a separate sample container for transport, the sorbent trap shall be thoroughly rinsed until all sample-wetted surfaces appear clean. Visible films should be removed by brushing. Whenever train components are brushed, the brush should be subsequently rinsed with solvent mixture and the rinsings added to this container.

7.2.6 **Container no. 6:** Note the color of the indicating silica gel to determine if it has been completely spent and make a notation of its condition. Transfer the silica gel from the fourth impinger to its original container and seal. A funnel may make it easier to pour the silica gel without spilling. A rubber policeman may be used as an aid in removing the silica gel from the impinger. It is not necessary to remove the small amount of dust particles that may adhere strongly to the impinger wall. Because the gain in weight is to be used for moisture calculations, do not use any water or other liquids to transfer the silica gel. If a balance is available in the field, weigh the container and its contents to 0.5 g or better.

7.3 Impinger water:

7.3.1 Make a notation of any color or film in the liquid catch. Measure the liquid in the first three impingers to within ±1 mL by using a graduated cylinder or by weighing it to within ±0.5 g by using a balance (if one is available). Record the volume or weight of liquid present. This information is required to calculate the moisture content of the effluent gas.

7.3.2 Discard the liquid after measuring and recording the volume or weight, unless analysis of the impinger catch is required (see Paragraph 4.1.3.7). Amber glass containers should be used for storage of impinger catch, if required.

7.3.3 If a different type of condenser is used, measure the amount of moisture condensed either volumetrically or gravimetrically.

7.4 Sample preparation for shipment: Prior to shipment, recheck all sample containers to ensure that the caps are well secured. Seal the lids of all containers around the circumference with Teflon tape. Ship all liquid samples upright on ice and all particulate filters with the particulate catch facing upward. The particulate filters should be shipped unrefrigerated.

8.0 ANALYSIS

8.1 Sample preparation:

8.1.1 **General:** The preparation steps for all samples will result in a finite volume of concentrated solvent. The final sample volume (usually in the 1- to 10-mL range) is then subjected to analysis by GC/MS. All samples should be inspected and the appearance documented. All samples are to be spiked with surrogate standards as received from the field prior to any sample manipulations. The spike should be at a level equivalent to 10 times the MDL when the solvent is reduced in volume to the desired level (i.e., 10 mL). The spiking compounds should be the stable isotopically labeled analog of the compounds of interest or a compound that would exhibit properties similar to the compounds of interest, be easily chromatographed, and not interfere with the analysis of the compounds of interest. Suggested surrogate spiking compounds are: deuterated naphthalene, chrysene, phenol, nitrobenzene, chlorobenzene, toluene, and carbon-13-labeled pentachlorophenol.

8.1.2 **Condensate:** The "condensate" is the moisture collected in the first impinger following the XAD-2 module. Spike the condensate with the surrogate standards. The volume is measured and recorded and then transferred to a separatory funnel. The pH is to be adjusted to pH 2 with 6 N sulfuric acid, if necessary. The sample container and graduated cylinder are sequentially rinsed with three successive 10-mL aliquots of the extraction solvent and added to the separatory funnel. The ratio of solvent to aqueous sample should be maintained at 1:3. Extract the sample by vigorously shaking the separatory funnel for 5 min. After complete separation of the phases, remove the solvent and transfer to a Kuderna-Danish concentrator (K-D), filtering through a bed of precleaned, dry sodium sulfate. Repeat the extraction step two additional times. Adjust the pH to 11 with 6 N sodium hydroxide and reextract combining the acid and base extracts. Rinse the sodium sulfate into the K-D with fresh solvent and discard the desiccant. Add Teflon boiling chips and concentrate to 10 mL by reducing the volume to slightly less than 10 mL and then bringing to volume with fresh solvent. In order to achieve the necessary detection limit, the sample volume can be further reduced to 1 mL by using a micro column K-D or nitrogen blow-down. Should the sample start to exhibit precipitation, the concentration step should be stopped and the sample redissolved with fresh solvent taking the volume to some finite amount. After adding a standard (for the purpose of quantitation by GC/MS), the sample is ready for analysis, as discussed in Paragraph 8.2.

8.1.3 **Impinger:** Spike the sample with the surrogate standards; measure and record the volume and transfer to a separatory funnel. Proceed as described in Paragraph 8.1.2.

8.1.4 **XAD-2:** Spike the resin directly with the surrogate standards. Transfer the resin to the all-glass thimbles by the following procedure (care should be taken so as not to contaminate the thimble by touching it with anything other than tweezers or other solvent-rinsed mechanical holding devices). Suspend the XAD-2 module directly over the thimble. The glass frit of the module (see Figure 2) should be in the up position. The thimble is contained in a clean beaker, which will serve to catch the solvent rinses. Using a Teflon squeeze bottle, flush the XAD-2 into the thimble. Thoroughly rinse the glass module with solvent into the beaker containing the thimble. Add the XAD-2 glass-wool plug to the thimble. Cover the XAD-2 in the thimble with a precleaned glass-wool plug sufficient to prevent the resin from floating into the solvent reservoir of the extractor. If the resin is wet, effective extraction can be accomplished by loosely packing the resin in the thimble. If a question arises concerning the completeness of the extraction, a second extraction, without a spike, is advised. The thimble is placed in the extractor and the rinse solvent contained in the beaker is added to the solvent reservoir. Additional solvent is added to make the reservoir approximately two-thirds full. Add Teflon boiling chips and assemble the apparatus. Adjust the heat source to cause the extractor to cycle 5-6 times per hr. Extract the resin for 16 hr. Transfer the solvent and three 10-mL rinses of the reservoir to a K-D and concentrate as described in Paragraph 8.1.2.

8.1.5 **Particulate filter (and cyclone catch):** If particulate loading is to be determined, weigh the filter (and cyclone catch, if applicable). The particulate filter (and cyclone catch, if applicable) is transferred to the glass thimble and extracted simultaneously with the XAD-2 resin.

8.1.6 **Train solvent rinses:** All train rinses (i.e., probe, impinger, filter housing) using the extraction solvent and methanol are returned to the laboratory as a single sample. If the rinses are contained in more than one container, the intended spike is divided equally among the containers proportioned from a single syringe volume. Transfer the rinse to a separatory funnel and add a sufficient amount of organic-free water so that the methylene chloride becomes immiscible and its volume no longer increases with the addition of more water. The extraction and concentration steps are then performed as described in Paragraph 8.1.2.

8.2 Sample analysis:

8.2.1 The primary analytical tool for the measurement of emissions from hazardous waste incinerators is GC/MS using fused-silica capillary GC columns, as described in Method 8270 in Chapter Four of this manual. Because of the nature of GC/MS instrumentation and the cost associated

with sample analysis, prescreening of the sample extracts by gas chromatography/flame ionization detection (GC/FID) or with electron capture (GC/ECD) is encouraged. Information regarding the complexity and concentration level of a sample prior to GC/MS analysis can be of enormous help. This information can be obtained by using either capillary columns or less expensive packed columns. However, the FID screen should be performed with a column similar to that used with the GC/MS. Keep in mind that GC/FID has a slightly lower detection limit than GC/MS and, therefore, that the concentration of the sample can be adjusted either up or down prior to analysis by GC/MS.

8.2.2 The mass spectrometer will be operated in a full scan (40-450) mode for most of the analyses. The range for which data are acquired in a GC/MS run will be sufficiently broad to encompass the major ions, as listed in Chapter Four, Method 8270, for each of the designated POHCs in an incinerator effluent analysis.

8.2.3 For most purposes, electron ionization (EI) spectra will be collected because a majority of the POHCs give reasonable EI spectra. Also, EI spectra are compatible with the NBS Library of Mass Spectra and other mass spectral references, which aid in the identification process for other components in the incinerator process streams.

8.2.4 To clarify some identifications, chemical ionization (CI) spectra using either positive ions or negative ions will be used to elucidate molecular-weight information and simplify the fragmentation patterns of some compounds. In no case, however, should CI spectra alone be used for compound identification. Refer to Chapter Four, Method 8270, for complete descriptions of GC conditions, MS conditions, and quantitative and quantitative identification.

9.0 CALIBRATION

9.1 Probe nozzle: Probe nozzles shall be calibrated before their initial use in the field. Using a micrometer, measure the inside diameter of the nozzle to the nearest 0.025 mm (0.001 in.). Make measurements at three separate places across the diameter and obtain the average of the measurements. The difference between the high and low numbers shall not exceed 0.1 mm (0.004 in.). When nozzles become nicked, dented, or corroded, they shall be reshaped, sharpened, and recalibrated before use. Each nozzle shall be permanently and uniquely identified.

9.2 Pitot tube: The Type S pitot tube assembly shall be calibrated according to the procedure outlined in Section 4 of EPA Method 2, or assigned a nominal coefficient of 0.84 if it is not visibly nicked, dented, or corroded and if it meets design and intercomponent spacing specifications.

9.3 Metering system:

9.3.1 Before its initial use in the field, the metering system shall be calibrated according to the procedure outlined in APTD-0576. Instead of physically adjusting the dry-gas meter dial readings to correspond to the wet-test meter readings, calibration factors may be used to correct the gas meter dial readings mathematically to the proper values. Before calibrating the metering system, it is suggested that a leak-check be conducted. For metering systems having diaphragm pumps, the normal leak-check procedure will not detect leakages within the pump. For these cases the following leak-check procedure is suggested: Make a 10-min calibration run at 0.00057 m^3/min (0.02 cfm); at the end of the run, take the difference of the measured wet-test and dry-gas meter volumes and divide the difference by 10 to get the leak rate. The leak rate should not exceed 0.00057 m^3/min (0.02 cfm).

9.3.2 After each field use, the calibration of the metering system shall be checked by performing three calibration runs at a single intermediate orifice setting (based on the previous field test). The vacuum shall be set at the maximum value reached during the test series. To adjust the vacuum, insert a valve between the wet-test meter and the inlet of the metering system. Calculate the average value of the calibration factor. If the calibration has changed by more than 5%, recalibrate the meter over the full range of orifice settings, as outlined in APTD-0576.

9.3.3 **Leak-check of metering system:** That portion of the sampling train from the pump to the orifice meter (see Figure 1) should be leak-checked prior to initial use and after each shipment. Leakage after the pump will result in less volume being recorded than is actually sampled. The following procedure is suggested (see Figure 6): Close the main valve on the meter box. Insert a one-hole rubber stopper with rubber tubing attached into the orifice exhaust pipe. Disconnect and vent the low side of the orifice manometer. Close off the low side orifice tap. Pressurize the system to 13-18 cm (5-7 in.) water column by blowing into the rubber tubing. Pinch off the tubing and observe the manometer for 1 min. A loss of pressure on the manometer indicates a leak in the meter box. Leaks, if present, must be corrected.

NOTE: If the dry-gas-meter coefficient values obtained before and after a test series differ by >5%, either the test series shall be voided or calculations for test series shall be performed using whichever meter coefficient value (i.e., before or after) gives the lower value of total sample volume.

9.4 Probe heater: The probe-heating system shall be calibrated before its initial use in the field according to the procedure outlined in APTD-0576. Probes constructed according to APTD-0581 need not be calibrated if the calibration curves in APTD-0576 are used.

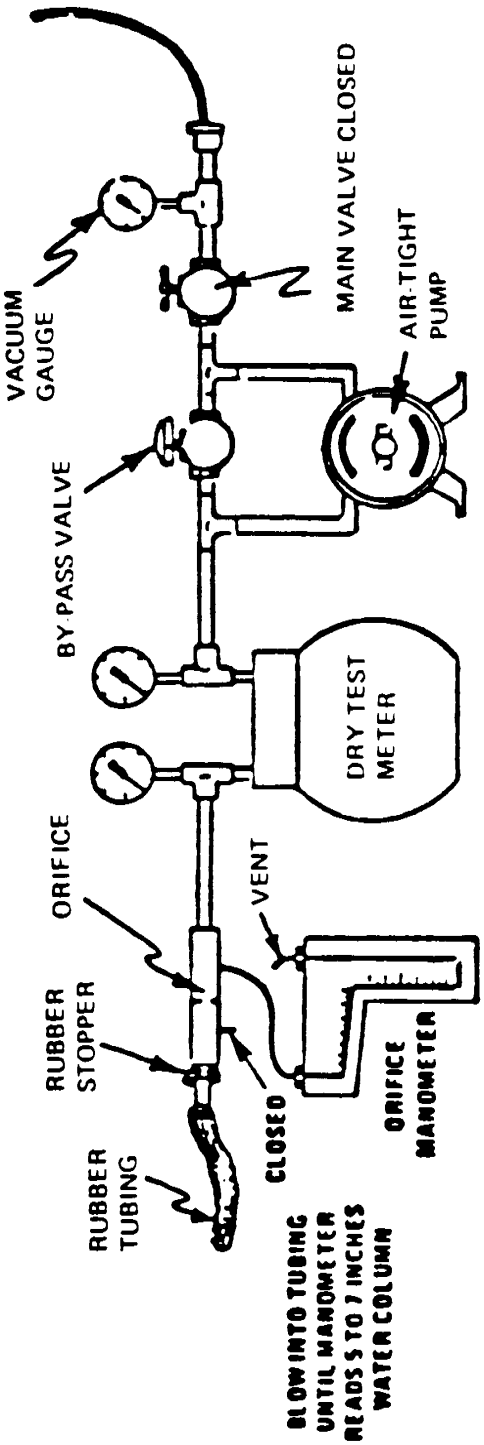

Figure 6. Leak-check of meter box.

9.5 Temperature gauges: Each thermocouple must be permanently and uniquely marked on the casting; all mercury-in-glass reference thermometers must conform to ASTM E-1 63C or 63F specifications. Thermocouples should be calibrated in the laboratory with and without the use of extension leads. If extension leads are used in the field, the thermocouple readings at ambient air temperatures, with and without the extension lead, must be noted and recorded. Correction is necessary if the use of an extension lead produces a change >1.5%.

9.5.1 **Impinger, organic module, and dry-gas meter thermocouples:** For the thermocouples used to measure the temperature of the gas leaving the impinger train and the XAD-2 resin bed, three-point calibration at ice-water, room-air, and boiling-water temperatures is necessary. Accept the thermocouples only if the readings at all three temperatures agree to ±2°C (3.6°F) with those of the absolute value of the reference thermometer.

9.5.2 **Probe and stack thermocouple:** For the thermocouples used to indicate the probe and stack temperatures, a three-point calibration at ice-water, boiling-water, and hot-oil-bath temperatures must be performed; it is recommended that room-air temperature be added, and that the thermometer and the thermocouple agree to within 1.5% at each of the calibration points. A calibration curve (equation) may be constructed (calculated) and the data extrapolated to cover the entire temperature range suggested by the manufacturer.

9.6 Barometer: Adjust the barometer initially and before each test series to agree to within ±25 mm Hg (0.1 in. Hg) of the mercury barometer or the corrected barometric pressure value reported by a nearby National Weather Service Station (same altitude above sea level).

9.7 Triple-beam balance: Calibrate the triple-beam balance before each test series, using Class-S standard weights; the weights must be within ±0.5% of the standards, or the balance must be adjusted to meet these limits.

10.0 CALCULATIONS

10.1 Carry out calculations. Round off figures after the final calculation to the correct number of significant figures.

10.2 Nomenclature:

A_n = Cross-sectional area of nozzle, m^2 (ft^2).

B_{ws} = Water vapor in the gas stream, proportion by volume.

C_d = Type S pitot tube coefficient (nominally 0.84 ± 0.02), dimensionless.

I = Percent of isokinetic sampling.

L_a = Maximum acceptable leakage rate for a leak-check, either pre-test or following a component change; equal to 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate, whichever is less.

L_i = Individual leakage rate observed during the leak-check conducted prior to the "i^{th}" component change (i = 1, 2, 3...n) m^3/min (cfm).

L_p = Leakage rate observed during the post-test leak-check, m^3/min (cfm).

M_d = Stack-gas dry molecular weight, g/g-mole (lb/lb-mole).

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).

P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg).

P_s = Absolute stack-gas pressure, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

R = Ideal gas constant, 0.06236 mm Hg-m^3/K-g-mole (21.85 in. Hg-ft^3/°R-lb-mole).

T_m = Absolute average dry-gas meter temperature (see Figure 6), K (°R).

T_s = Absolute average stack-gas temperature (see Figure 6), K (°R).

T_{std} = Standard absolute temperature, 293K (528°R).

V_{lc} = Total volume of liquid collected in the organic module condensate knockout trap, the impingers, and silica gel, mL.

V_m = Volume of gas sample as measured by dry-gas meter, dscm (dscf).

$V_{m(std)}$ = Volume of gas sample measured by the dry-gas meter, corrected to standard conditions, dscm (dscf).

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).

V_s = Stack-gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 5, m/sec (ft/sec).

W_a = Weight of residue in acetone wash, mg.

γ = Dry-gas-meter calibration factor, dimensionless.

ΔH = Average pressure differential across the orifice meter (see Figure 2), mm H_2O (in. H_2O).

ρ_w = Density of water, 0.9982 g/mL (0.002201 lb/mL).

θ = Total sampling time, min.

θ_1 = Sampling time interval from the beginning of a run until the first component change, min.

θ_i = Sampling time interval between two successive component changes, beginning with the interval between the first and second changes, min.

θ_p = Sampling time interval from the final (n^{th}) component change until the end of the sampling run, min.

13.6 = Specific gravity of mercury.

60 = sec/min.

100 = Conversion to percent.

10.3 Average dry-gas-meter temperature and average orifice pressure drop: See data sheet (Figure 5, above).

10.4 Dry-gas volume: Correct the sample measured by the dry-gas meter to standard conditions (20°C, 760 mm Hg [68°F, 29.92 in. Hg]) by using Equation 1:

$$V_{m(std)} = V_m Y \frac{T_{std}}{T_m} \frac{P_{bar} + \Delta H/13.6}{P_{std}} = K_1 V_m Y \frac{P_{bar} + \Delta H/13.6}{T_m} \qquad (1)$$

where:

K_1 = 0.3858 K/mm Hg for metric units, or
K_1 = 17.64°R/in. Hg for English units.

It should be noted that Equation 1 can be used as written, unless the leakage rate observed during any of the mandatory leak-checks (i.e., the post-test leak-check or leak-checks conducted prior to component changes) exceeds L_a. If L_p or L_i exceeds L_a, Equation 1 must be modified as follows:

a. Case I (no component changes made during sampling run): Replace V_m in Equation 1 with the expression:

$$V_m - (L_p - L_a)$$

b. Case II (one or more component changes made during the sampling run): Replace V_m in Equation 1 by the expression:

$$V_m - (L_1 - L_a)\theta_1 - \sum_{i=2}^{n} (L_i - L_a)\theta_1 - (L_p - L_a)\theta_p$$

and substitute only for those leakage rates (L_1 or L_p) that exceed L_a.

10.5 Volume of water vapor:

$$V_{w(std)} = V_{lc} \frac{P_w}{M_w} \frac{RT_{std}}{P_{std}} = K_2 V_{lc} \quad (2)$$

where:

K_2 = 0.001333 m^3/mL for metric units, or
K_2 = 0.04707 ft^3/mL for English units.

10.6 Moisture content:

$$B_{ws} = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}} \quad (3)$$

NOTE: In saturated or water-droplet-laden gas streams, two calculations of the moisture content of the stack gas shall be made, one from the impinger analysis (Equation 3) and a second from the assumption of saturated conditions. The lower of the two values of B_w shall be considered correct. The procedure for determining the moisture content based upon assumption of saturated conditions is given in the Note to Section 1.2 of Method 4. For the purposes of this method, the average stack-gas temperature from Figure 6 may be used to make this determination, provided that the accuracy of the in-stack temperature sensor is ±1°C (2°F).

10.7 Conversion factors:

From	To	Multiply by
scf	m^3	0.02832
g/ft^3	gr/ft^3	15.43
g/ft^3	lb/ft^3	2.205×10^{-3}
g/ft^3	g/m^3	35.31

10.8 Isokinetic variation:

10.8.1 **Calculation from raw data:**

$$I = \frac{100\ T_s[K_3 F_{lc} + (V_m/T_m)\ (P_{bar} + \Delta H/13.6)]}{60\theta V_s P_s A_n} \qquad (4)$$

where:

K_3 = 0.003454 mm Hg-m^3/mL-K for metric units, or
K_3 = 0.002669 in. Hg-ft^3/mL-°R for English units.

10.8.2 **Calculation for intermediate values:**

$$I = \frac{T_s V_{m(std)} P_{std} 100}{T_{std} V_s \theta A_n P_s 60(1-B_{ws})} \qquad (5)$$

$$= K_4 \frac{T_s V_{m(std)}}{P_s V_s A_n \theta (1-B_{ws})}$$

where:

K_4 = 4.320 for metric units, or
K_4 = 0.09450 for English units.

10.8.3 **Acceptable results:** If 90% $\leq$ I $\leq$ 110%, the results are acceptable. If the results are low in comparison with the standard and I is beyond the acceptable range, or if I is less than 90%, the Administrator may opt to accept the results.

10.9 To determine the minimum sample volume that shall be collected, the following sequence of calculations shall be used.

10.9.1 From prior analysis of the waste feed, the concentration of POHCs introduced into the combustion system can be calculated. The degree of destruction and removal efficiency that is required is used to determine the maximum amount of POHC allowed to be present in the effluent. This may be expressed as:

$$\frac{(WF)\ (POHC_i\ conc)}{100} \ \frac{(100\text{-}\%DRE)}{100} = \text{Max } POHC_i \text{ Mass} \qquad (6)$$

where:

WF = mass flow rate of waste feed per hr, g/hr (lb/hr).

$POHC_i$ = concentration of Principal Organic Hazardous Compound (wt %) introduced into the combustion process.

DRE = percent Destruction and Removal Efficiency required.

Max POHC = mass flow rate (g/hr [lb/hr]) of POHC emitted from the combustion source.

10.9.2 The average discharge concentration of the POHC in the effluent gas is determined by comparing the Max POHC with the volumetric flow rate being exhausted from the source. Volumetric flow rate data are available as a result of preliminary Method 1-4 determinations:

$$\frac{\text{Max POHC}_i \text{ Mass}}{DV_{eff(std)}} = \text{Max POHC}_i \text{ conc} \qquad (7)$$

where:

$DV_{eff(std)}$ = volumetric flow rate of exhaust gas, dscm (dscf).

$POHC_i$ conc = anticipated concentration of the POHC in the exhaust gas stream, g/dscm (lb/dscf).

10.9.3 In making this calculation, it is recommended that a safety margin of at least ten be included:

$$\frac{LDL_{POHC} \times 10}{POHC_i \text{ conc}} = V_{TBC} \qquad (8)$$

where:

LDL_{POHC} = detectable amount of POHC in entire sampling train.

NOTE: The whole extract from an XAD-2 cartridge is seldom if ever, injected at once. Therefore, if aliquoting factors are involved, the LDL_{POHC} is not the same as the analytical (or column) detection limit.

V_{TBC} = minimum dry standard volume to be collected at dry-gas meter.

10.10 Concentration of any given POHC in the gaseous emissions of a combustion process:

1) Multiply the concentration of the POHC as determined in Method 8270 by the final concentration volume, typically 10 mL.

C_{POHC} (ug/mL) x sample volume (mL) = amount (ug) of POHC in sample (9)

where:

C_{POHC} = concentration of POHC as analyzed by Method 8270.

2) Sum the amount of POHC found in all samples associated with a single train.

Total (ug) = XAD-2 (ug) + condensate (ug) + rinses (ug) + impinger (ug) (10)

3) Divide the total ug found by the volume of stack gas sampled (m^3).

(Total ug)/(train sample volume) = concentration of POHC (ug/m^3) (11)

11.0 QUALITY CONTROL

11.1 Sampling: See EPA Manual 600/4-77-027b for Method 5 quality control.

11.2 Analysis: The quality assurance program required for this study includes the analysis of field and method blanks, procedure validations, incorporation of stable labeled surrogate compounds, quantitation versus stable labeled internal standards, capillary column performance checks, and external performance tests. The surrogate spiking compounds selected for a particular analysis are used as primary indicators of the quality of the analytical data for a wide range of compounds and a variety of sample matrices. The assessment of combustion data, positive identification, and quantitation of the selected compounds are dependent on the integrity of the samples received and the precision and accuracy of the analytical methods employed. The quality assurance procedures for this method are designed to monitor the performance of the analytical method and to provide the required information to take corrective action if problems are observed in laboratory operations or in field sampling activities.

11.2.1 **Field Blanks:** Field blanks must be submitted with the samples collected at each sampling site. The field blanks include the sample bottles containing aliquots of sample recovery solvents, unused filters, and resin cartridges. At a minimum, one complete sampling train will be assembled in the field staging area, taken to the sampling area, and leak-checked at the beginning and end of the testing (or for the same total number of times as the actual test train). The filter housing and probe of the blank train will be heated during the sample test. The train will be recovered as if it were an actual test sample. No gaseous sample will be passed through the sampling train.

11.2.2 **Method blanks:** A method blank must be prepared for each set of analytical operations, to evaluate contamination and artifacts that can be derived from glassware, reagents, and sample handling in the laboratory.

11.2.3 Refer to Method 8270 for additional quality control considerations.

12.0 METHOD PERFORMANCE

12.1 Method performance evaluation: Evaluation of analytical procedures for a selected series of compounds must include the sample-preparation procedures and each associated analytical determination. The analytical procedures should be challenged by the test compounds spiked at appropriate levels and carried through the procedures.

12.2 Method detection limit: The overall method detection limits (lower and upper) must be determined on a compound-by-compound basis because different compounds may exhibit different collection, retention, and extraction efficiencies as well as instrumental minimum detection limit (MDL). The method detection limit must be quoted relative to a given sample volume. The upper limits for the method must be determined relative to compound retention volumes (breakthrough).

12.3 Method precision and bias: The overall method precision and bias must be determined on a compound-by-compound basis at a given concentration level. The method precision value would include a combined variability due to sampling, sample preparation, and instrumental analysis. The method bias would be dependent upon the collection, retention, and extraction efficiency of the train components. From evaluation studies to date using a dynamic spiking system, method biases of -13% and -16% have been determined for toluene and 1,1,2,2-tetrachloroethane, respectively. A precision of 19.9% was calculated from a field test data set representing seven degrees of freedom which resulted from a series of paired, unspiked Semivolatile Organic Sampling trains (Semi-VOST) sampling emissions from a hazardous waste incinerator.

PREPARATION OF XAD-2 SORBENT RESIN

1.0 SCOPE AND APPLICATION

1.1 XAD-2 resin as supplied by the manufacturer is impregnated with a bicarbonate solution to inhibit microbial growth during storage. Both the salt solution and any residual extractable monomer and polymer species must be removed before use. The resin is prepared by a series of water and organic extractions, followed by careful drying.

2.0 EXTRACTION

2.1 Method 1: The procedure may be carried out in a giant Soxhlet extractor. An all-glass thimble containing an extra-coarse frit is used for extraction of XAD-2. The frit is recessed 10-15 mm above a crenellated ring at the bottom of the thimble to facilitate drainage. The resin must be carefully retained in the extractor cup with a glass-wool plug and stainless steel screen because it floats on methylene chloride. This process involves sequential extraction in the following order.

Solvent	Procedure
Water	Initial rinse: Place resin in a beaker, rinse once with Type II water, and discard. Fill with water a second time, let stand overnight, and discard.
Water	Extract with H_2O for 8 hr.
Methyl alcohol	Extract for 22 hr.
Methylene chloride	Extract for 22 hr.
Methylene chloride (fresh)	Extract for 22 hr.

2.2 Method 2:

2.2.1 As an alternative to Soxhlet extraction, a continuous extractor has been fabricated for the extraction sequence. This extractor has been found to be acceptable. The particular canister used for the apparatus shown in Figure A-1 contains about 500 g of finished XAD-2. Any size may be constructed; the choice is dependent on the needs of the sampling programs. The XAD-2 is held under light spring tension between a pair of coarse and fine screens. Spacers under the bottom screen allow for even distribution of clean solvent. The three-necked flask should be of sufficient size (3-liter in this case) to hold solvent

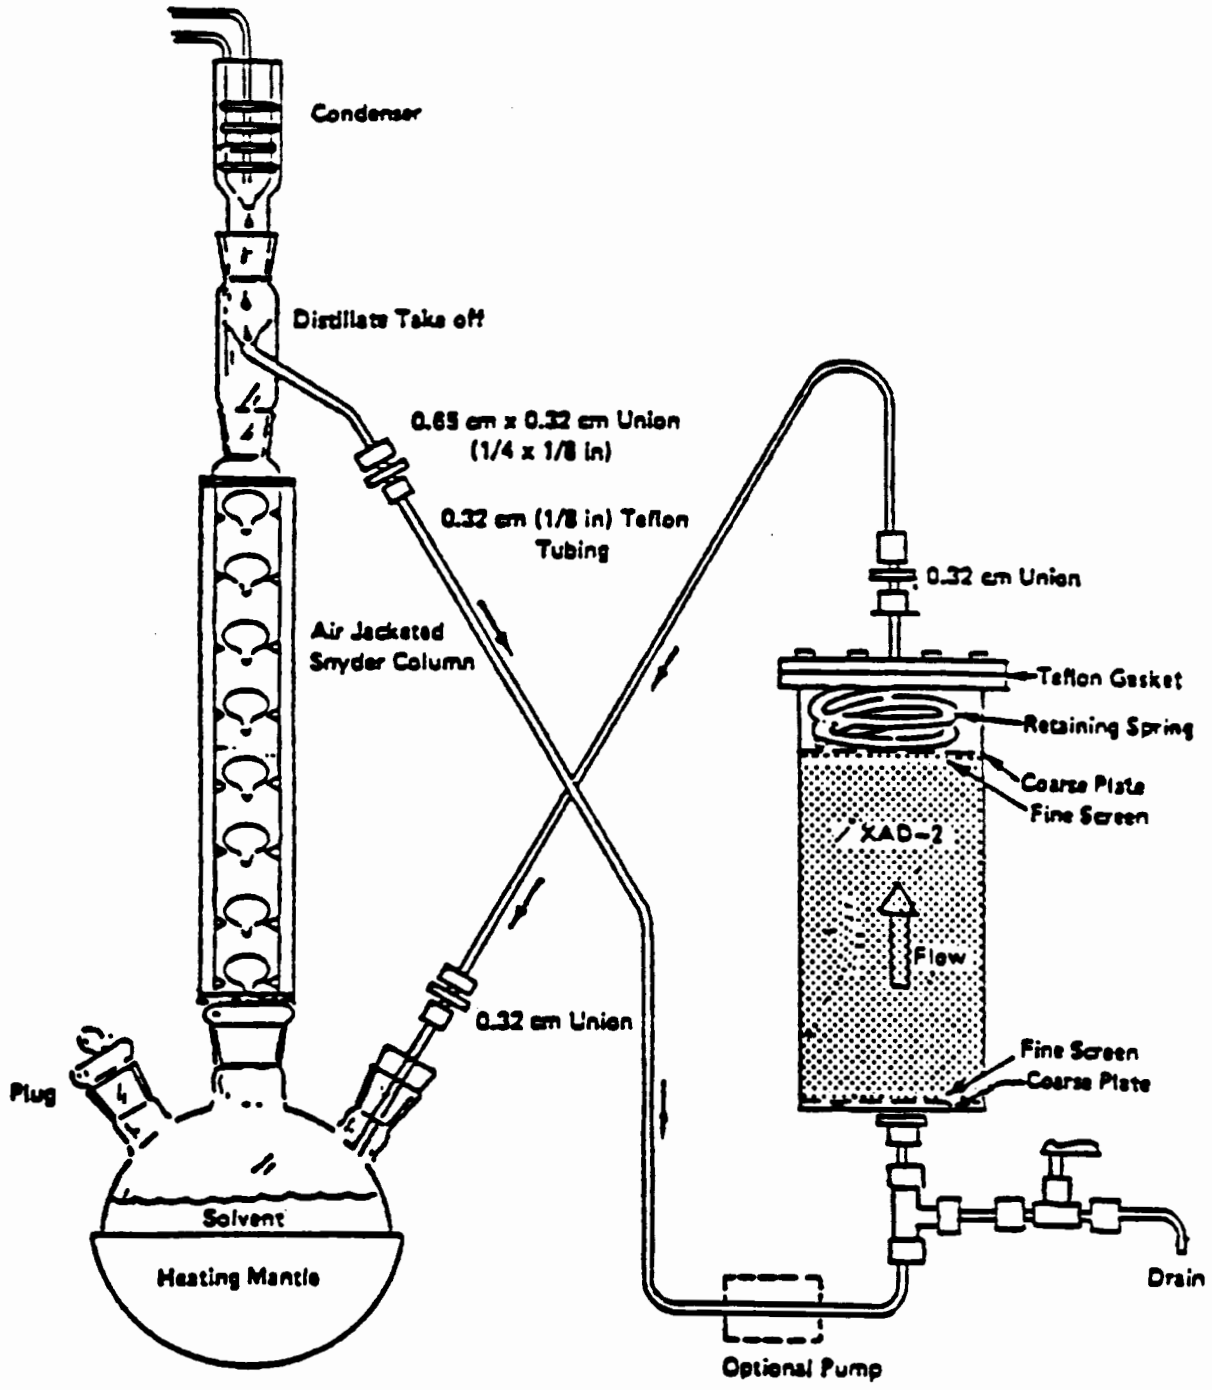

Figure A-1. XAD-2 cleanup extraction apparatus.

equal to twice the dead volume of the XAD-2 canister. Solvent is refluxed through the Snyder column, and the distillate is continuously cycled up through the XAD-2 for extraction and returned to the flask. The flow is maintained upward through the XAD-2 to allow maximum solvent contact and prevent channeling. A valve at the bottom of the canister allows removal of solvent from the canister between changes.

2.2.2 Experience has shown that it is very difficult to cycle sufficient water in this mode. Therefore the aqueous rinse is accomplished by simply flushing the canister with about 20 liters of distilled water. A small pump may be useful for pumping the water through the canister. The water extraction should be carried out at the rate of about 20-40 mL/min.

2.2.3 After draining the water, subsequent methyl alcohol and methylene chloride extractions are carried out using the refluxing apparatus. An overnight or 10- to 20-hr period is normally sufficient for each extraction.

2.2.4 All materials of construction are glass, Teflon, or stainless steel. Pumps, if used, should not contain extractable materials. Pumps are not used with methanol and methylene chloride.

3.0 DRYING

3.1 After evaluation of several methods of removing residual solvent, a fluidized-bed technique has proved to be the fastest and most reliable drying method.

3.2 A simple column with suitable retainers, as shown in Figure A-2, will serve as a satisfactory column. A 10.2-cm (4-in.) Pyrex pipe 0.6 m (2 ft) long will hold all of the XAD-2 from the extractor shown in Figure A-1 or the Soxhlet extractor, with sufficient space for fluidizing the bed while generating a minimum resin load at the exit of the column.

3.3 Method 1: The gas used to remove the solvent is the key to preserving the cleanliness of the XAD-2. Liquid nitrogen from a standard commercial liquid nitrogen cylinder has routinely proved to be a reliable source of large volumes of gas free from organic contaminants. The liquid nitrogen cylinder is connected to the column by a length of precleaned 0.95-cm (3/8-in.) copper tubing, coiled to pass through a heat source. As nitrogen is bled from the cylinder, it is vaporized in the heat source and passes through the column. A convenient heat source is a water bath heated from a steam line. The final nitrogen temperature should only be warm to the touch and not over 40°C. Experience has shown that about 500 g of XAD-2 may be dried overnight by consuming a full 160-liter cylinder of liquid nitrogen.

3.4 Method 2: As a second choice, high-purity tank nitrogen may be used to dry the XAD-2. The high-purity nitrogen must first be passed through a bed

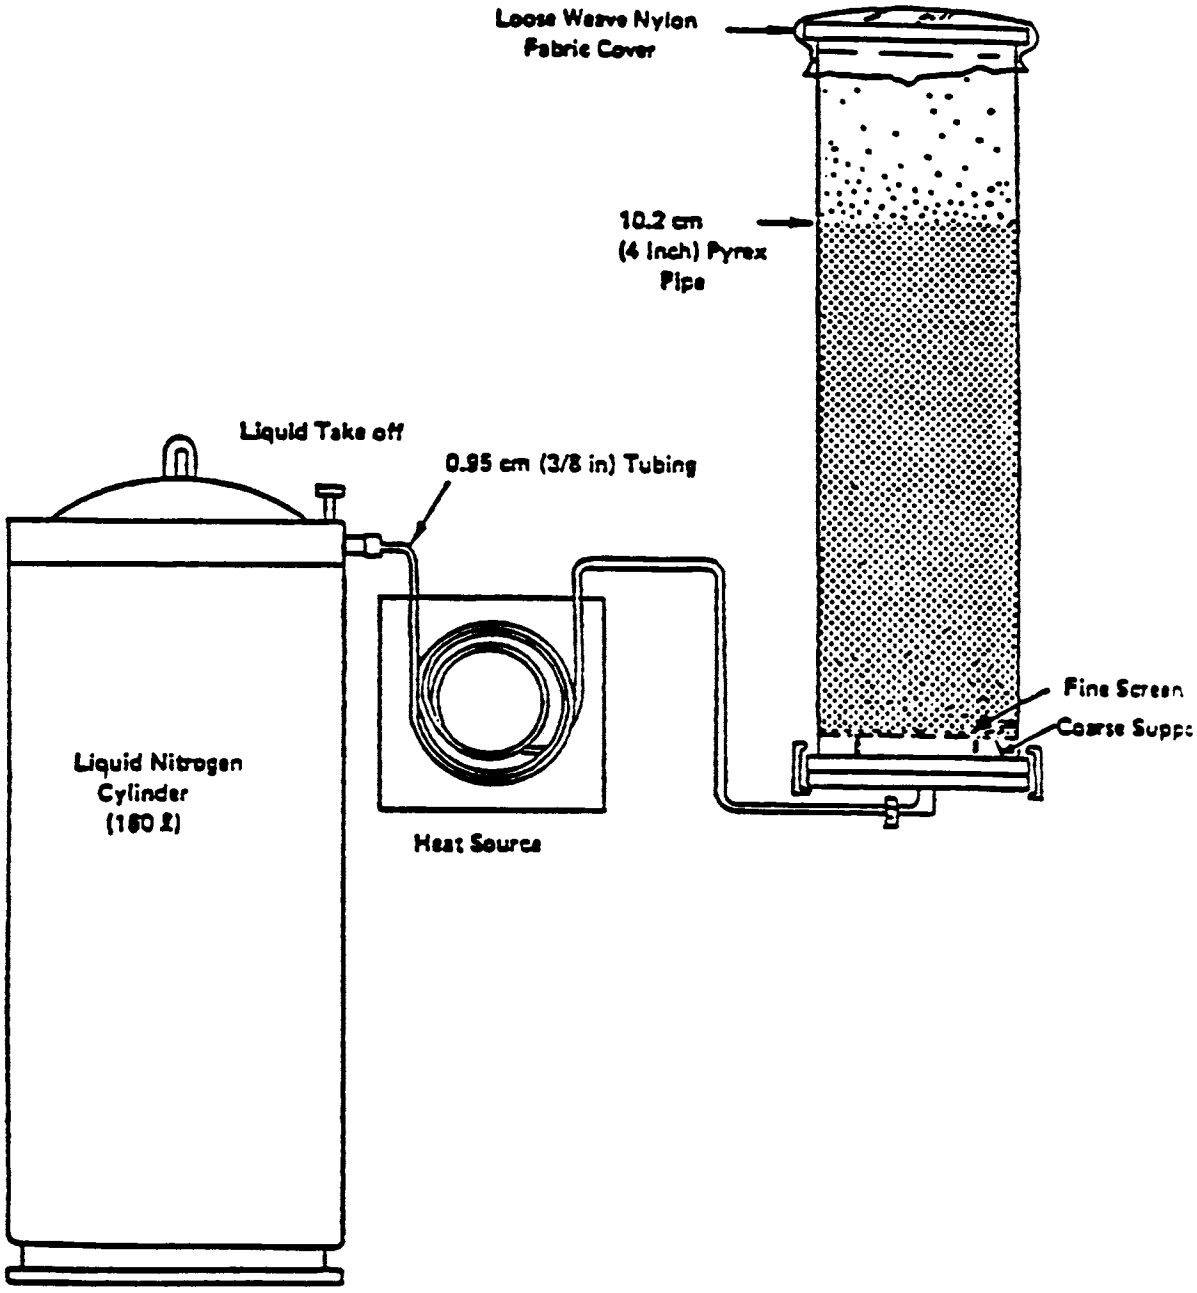

Figure A-2. XAD-2 fluidized-bed drying apparatus.

of activated charcoal approximately 150 mL in volume. With either type of drying method, the rate of flow should gently agitate the bed. Excessive fluidization may cause the particles to break up.

4.0 QUALITY CONTROL PROCEDURES

4.1 For both Methods 1 and 2, the quality control results must be reported for the batch. The batch must be reextracted if the residual extractable organics are >20 ug/mL by TCO analysis or the gravimetric residue is >0.5 mg/20 g XAD-2 extracted. (See also section 5.1, Method 0010.)

4.2 Four control procedures are used with the final XAD-2 to check for (1) residual methylene chloride, (2) extractable organics (TCO), (3) specific compounds of interest as determined by GC/MS, as described in Section 4.5 below, and (4) residue (GRAV).

4.3 Procedure for residual methylene chloride:

4.3.1 **Description:** A 1±0.1-g sample of dried resin is weighed into a small vial, 3 mL of toluene are added, and the vial is capped and well shaken. Five uL of toluene (now containing extracted methylene chloride) are injected into a gas chromatograph, and the resulting integrated area is compared with a reference standard. The reference solution consists of 2.5 uL of methylene chloride in 100 mL of toluene, simulating 100 ug of residual methylene chloride on the resin. The acceptable maximum content is 1,000 ug/g resin.

4.3.2 **Experimental:** The gas chromatograph conditions are as follows:

6-ft x 1/8-in. stainless steel column containing 10% OV-101 on 100/120 Supelcoport;

Helium carrier at 30 mL/min;

FID operated on 4 x 10^{-11} A/mV;

Injection port temperature: 250°C;

Detector temperature: 305°C;

Program: 30°C(4 min) 40°C/min 250°C (hold); and

Program terminated at 1,000 sec.

4.4 Procedure for residual extractable organics:

4.4.1 **Description:** A 20±0.1-g sample of cleaned, dried resin is weighed into a precleaned alundum or cellulose thimble which is plugged with cleaned glass wool. (Note that 20 g of resin will fill a thimble, and the

resin will float out unless well plugged.) The thimble containing the resin is extracted for 24 hr with 200-mL of pesticide- grade methylene chloride (Burdick and Jackson pesticide-grade or equivalent purity). The 200-mL extract is reduced in volume to 10-mL using a Kuderna-Danish concentrator and/or a nitrogen evaporation stream. Five uL of that solution are analyzed by gas chromatography using the TCO analysis procedure. The concentrated solution should not contain >20 ug/mL of TCO extracted from the XAD-2. This is equivalent to 10 ug/g of TCO in the XAD-2 and would correspond to 1.3 mg of TCO in the extract of the 130-g XAD-2 module. Care should be taken to correct the TCO data for a solvent blank prepared (200 mL reduced to 10 mL) in a similar manner.

4.4.2 **Experimental:** Use the TCO analysis conditions described in the revised Level 1 manual (EPA 600/7-78-201).

4.5 GC/MS Screen: The extract, as prepared in paragraph 4.4.1, is subjected to GC/MS analysis for each of the individual compounds of interest. The GC/MS procedure is described in Chapter Four, Method 8270. The extract is screened at the MDL of each compound. The presence of any compound at a concentration >25 ug/mL in the concentrated extract will require the XAD-2 to be recleaned by repeating the methylene chloride step.

4.6 Methodology for residual gravimetric determination: After the TCO value and GC/MS data are obtained for the resin batch by the above procedures, dry the remainder of the extract in a tared vessel. There must be <0.5 mg residue registered or the batch of resin will have to be extracted with fresh methylene chloride again until it meets this criterion. This level corresponds to 25 ug/g in the XAD-2, or about 3.25 mg in a resin charge of 130 g.

TOTAL CHROMATOGRAPHABLE ORGANIC MATERIAL ANALYSIS

1.0 SCOPE AND APPLICATION

1.1 In this procedure, gas chromatography is used to determine the quantity of lower boiling hydrocarbons (boiling points between 90° and 300°C) in the concentrates of all organic solvent rinses, XAD-2 resin and LC fractions - when Method 1 is used (see References, Method 0010) - encountered in Level 1 environmental sample analyses. Data obtained using this procedure serve a twofold purpose. First, the total quantity of the lower boiling hydrocarbons in the sample is determined. Then whenever the hydrocarbon concentrations in the original concentrates exceed 75 ug/m^3, the chromatography results are reexamined to determine the amounts of individual species.

The extent of compound identification is limited to representing all materials as normal alkanes based upon comparison of boiling points. Thus the method is not qualitative. In a similar manner, the analysis is semiquantitative; calibrations are prepared using only one hydrocarbon. They are replicated but samples routinely are not.

1.2 Application: This procedure applies solely to the Level 1 C7-C16 gas chromatographic analysis of concentrates of organic extracts, neat liquids, and of LC fractions. Throughout the procedure, it is assumed the analyst has been given a properly prepared sample.

1.3 Sensitivity: The sensitivity of this procedure, defined as the slope of a plot of response versus concentration, is dependent on the instrument and must be verified regularly. TRW experience indicates the nominal range is of the order of 77 uV·V·sec·uL/ng of n-heptane and 79 uV·sec·ul/ng of n-hexadecane. The instrument is capable of perhaps one hundredfold greater sensitivity. The level specified here is sufficient for Level 1 analysis.

1.4 Detection limit: The detection limit of this procedure as written is 1.3 ng/uL for a 1 uL injection of n-decane. This limit is arbitrarily based on defining the minimum detectable response as 100 uv·sec. This is an easier operational definition than defining the minimum detection limit to be that amount of material which yields a signal twice the noise level.

1.5 Range: The range of the procedure will be concentrations of 1.3 ng/uL and greater.

1.6 Limitations

1.6.1 **Reporting limitations:** It should be noted that a typical environmental sample will contain compounds which: (a) will not elute in the specified boiling ranges and thus will not be reported, and/or (b)

will not elute from the column at all and thus will not be reported. Consequently, the organic content of the sample as reported is a lower bound and should be regarded as such.

1.6.2 **Calibration limitations:** Quantitation is based on calibration with n-decane. Data should therefore be reported as, e.g., mg C8/m^3 as n-decane. Since response varies linearly with carbon number (over a wide range the assumption may involve a 20% error), it is clear that heptane (C7) detected in a sample and quantitated as decane will be overestimated. Likewise, hexadecane (C16) quantitated as decane will be underestimated. From previous data, it is estimated the error involved is on the order of 6-7%.

1.6.3 **Detection limitations:** The sensitivity of the flame ionization detector varies from compound to compound. However, n-alkanes have a greater response than other classes. Consequently, using an n-alkane as a calibrant and assuming equal responses of all other compounds tends to give low reported values.

2.0 SUMMARY OF METHOD

2.1 A mL aliquot of all 10-mL concentrates is disbursed for GC-TCO analysis. With boiling point-retention time and response-amount calibration curves, the data (peak retention times and peak areas) are interpreted by first summing peak areas in the ranges obtained from the boiling point-retention time calibration. Then, with the response-amount calibration curve, the area sums are converted to amounts of material in the reported boiling point ranges.

2.2 After the instrument is set up, the boiling point-retention time calibration is effected by injecting a mixture of n-C7 through n-C16 hydrocarbons and operating the standard temperature program. Response-quantity calibrations are accomplished by injecting n-decane in n-pentane standards and performing the standard temperature program.

2.3 Definitions

2.3.1 **GC:** Gas chromatography or gas chromatograph.

2.3.2 **C7-C16 n-alkanes:** Heptane through hexadecane.

2.3.3 **GCA temperature program:** 4 min isothermal at 60°C, 10°C/min from 60° to 220°C.

2.3.4 **TRW temperature program:** 5 min isothermal at room temperature, then program from 30°C to 250°C at 15°C/min.

3.0 INTERFERENCES

Not applicable.

4.0 APPARATUS AND MATERIALS

4.1 Gas chromatograph: This procedure is intended for use on a Varian 1860 gas chromatograph, equipped with dual flame ionization detectors and a linear temperature programmer. Any equivalent instrument can be used provided that electrometer settings, etc., be changed appropriately.

4.2 Gases:

4.2.1 **Helium:** Minimum quality is reactor grade. A 4A or 13X molecular sieve drying tube is required. A filter must be placed between the trap and the instrument. The trap should be recharged after every third tank of helium.

4.2.2 **Air:** Zero grade is satisfactory.

4.2.3 **Hydrogen:** Zero grade.

4.3 Syringe: Syringes are Hamilton 701N, 10 uL, or equivalent.

4.4 Septa: Septa will be of such quality as to produce very low bleed during the temperature program. An appropriate septum is Supelco Microsep 138, which is Teflon-backed. If septum bleed cannot be reduced to a negligible level, it will be necessary to install septum swingers on the instrument.

4.5 Recorder: The recorder of this procedure must be capable of not less than 1 mV full-scale display, a 1-sec time constant and 0.5 in. per min chart rate.

4.6 Integrator: An integrator is required. Peak area measurement by hand is satisfactory but too time-consuming. If manual integration is required, the method of "height times width at half height" is used.

4.7 Columns:

4.7.1 **Preferred column:** 6 ft x 1/8 in. O.D. stainless steel column of 10% OV-101 on 100/120 mesh Supelcoport.

4.7.2 **Alternate column:** 6 ft x 1/8 in. O.D. stainless steel column of 10% OV-1 (or other silicon phase) on 100/120 mesh Supelcoport.

4.8 Syringe cleaner: Hamilton syringe cleaner or equivalent connected to a suitable vacuum source.

5.0 REAGENTS

5.1 Pentane: "Distilled-in-Glass" (reg. trademark) or "Nanograde" (reg. trademark) for standards and for syringe cleaning.

5.2 Methylene chloride: "Distilled-in-Glass" (reg. trademark) or "Nanograde" (reg. trademark) for syringe cleaning.

6.0 SAMPLING HANDLING AND PRESERVATION

6.1 The extracts are concentrated in a Kuderna-Danish evaporator to a volume less than 10 mL. The concentrate is then quantitatively transferred to a 10-mL volumetric flask and diluted to volume. A 1-mL aliquot is taken for both this analysis and possible subsequent GC/MS analysis and set aside in the sample bank. For each GC-TCO analysis, obtain the sample sufficiently in advance to allow it to warm to room temperature. For example, after one analysis is started, return that sample to the sample bank and take the next sample.

7.0 PROCEDURES

7.1 Setup and checkout: Each day, the operator will verify the following:

7.1.1 That supplies of carrier gas, air and hydrogen are sufficient, i.e., that each tank contains > 100 psig.

7.1.2 That, after replacement of any gas cylinder, all connections leading to the chromatograph have been leak-checked.

7.1.3 That the carrier gas flow rate is 30 $\pm$ 2 mL/min, the hydrogen flow rate is 30 $\pm$ 2 mL/min, and the air flow rate is 300 $\pm$ 20 mL/min.

7.1.4 That the electrometer is functioning properly.

7.1.5 That the recorder and integrator are functioning properly.

7.1.6 That the septa have been leak-checked (leak-checking is effected by placing the soap bubble flow meter inlet tube over the injection port adaptors), and that no septum will be used for more than 20 injections.

7.1.7 That the list of samples to be run is ready.

7.2 Retention time calibration:

7.2.1 To obtain the temperature ranges for reporting the results of the analyses, the chromatograph is given a normal boiling point-retention time calibration. The n-alkanes, their boiling points, and data reporting ranges are given in the table below:

	NBP, °C	Reporting Range, °C	Report As
n-heptane	98	90-110	C7
n-octane	126	110-140	C8
n-nonane	151	140-160	C9
n-decane	174	160-180	C10
n-undecane	194	180-200	C11
n-dodecane	214	200-220	C12
n-tridecane	234	220-240	C13
n-tetradecane	252	240-260	C14
n-pentadecane	270	260-280	C15
n-hexadecane	288	280-300	C16

7.2.2 **Preparation of standards:** Preparing a mixture of the C7-C16 alkanes is required. There are two approaches: (1) use of a standards kit (e.g., Polyscience Kit) containing bottles of mixtures of selected n-alkanes which may be combined to produce a C7-C16 standard; or (2) use of bottles of the individual C7-C16 alkanes from which accurately known volumes may be taken and combined to give a C7-C16 mixture.

7.2.3 **Procedure for retention time calibration:** This calibration is performed at the start of an analytical program; the mixture is chromatographed at the start of each day. To attain the required retention time precision, both the carrier gas flow rate and the temperature program specifications must be observed. Details of the procedure depend on the instrument being used. The general procedure is as follows:

7.2.3.1 Set the programmer upper limit at 250°C. If this setting does not produce a column temperature of 250°C, find the correct setting.

7.2.3.2 Set the programmer lower limit at 30°C.

7.2.3.3 Verify that the instrument and samples are at room temperature.

7.2.3.4 Inject 1 uL of the n-alkane mixture.

7.2.3.5 Start the integrator and recorder.

7.2.3.6 Allow the instrument to run isothermally at room temperature for five min.

7.2.3.7 Shut the oven door.

7.2.3.8 Change the mode to Automatic and start the temperature program.

7.2.3.9 Repeat Steps 1-9 a sufficient number of times so that the relative standard deviation of the retention times for each peak is <5%.

7.3 Response calibration:

7.3.1 For the purposes of a Level 1 analysis, response-quantity calibration with n-decane is adequate. A 10-uL volume of n-decane is injected into a tared 10 mL volumetric flask. The weight injected is obtained and the flask is diluted to the mark with n-pentane. This standard contains about 730 ng n-decane per uL n-pentane. The exact concentration depends on temperature, so that a weight is required. Two serial tenfold dilutions are made from this standard, giving standards at about 730, 73, and 7.3 ng n-decane per uL n-pentane, respectively.

7.3.2 **Procedure for response calibration:** This calibration is performed at the start of an analytical program and monthly thereafter. The most concentrated standard is injected once each day. Any change in calibration necessitates a full calibration with new standards. Standards are stored in the refrigerator locker and are made up monthly.

7.3.2.1 Verify that the instrument is set up properly.

7.3.2.2 Set electrometer at 1×10^{-10} A/mV.

7.3.2.3 Inject 1 uL of the highest concentration standard.

7.3.2.4 Run standard temperature program as specified above.

7.3.2.5 Clean syringe.

7.3.2.6 Make repeated injections of all three standards until the relative standard deviations of the areas of each standard are ≤5%.

7.4 Sample analysis procedure:

7.4.1 The following apparatus is required:

7.4.1.1 **Gas chromatograph** set up and working.

7.4.1.2 **Recorder, integrator** working.

7.4.1.3 **Syringe and syringe cleaning apparatus.**

7.4.1.4 **Parameters:** Electrometer setting is 1×10^{-10} A/mV; recorder is set at 0.5 in./min and 1 mV full-scale.

7.4.2 Steps in the procedure are:

7.4.2.1 Label chromatogram with the data, sample number, etc.

7.4.2.2 Inject sample.

7.4.2.3 Start integrator and recorder.

7.4.2.4 After isothermal operation for 5 min, begin temperature program.

7.4.2.5 Clean syringe.

7.4.2.6 Return sample; obtain new sample.

7.4.2.7 When analysis is finished, allow instrument to cool. Turn chromatogram and integrator output and data sheet over to data analyst.

7.5 Syringe cleaning procedure:

7.5.1 Remove plunger from syringe.

7.5.2 Insert syringe into cleaner; turn on aspirator.

7.5.3 Fill pipet with pentane; run pentane through syringe.

7.5.4 Repeat with methylene chloride from a separate pipet.

7.5.5 Flush plunger with pentane followed by methylene chloride.

7.5.6 Repeat with methylene chloride.

7.6 Sample analysis decision criterion: The data from the TCO analyses of organic extract and rinse concentrates are first used to calculate the total concentration of C7-C16 hydrocarbon-equivalents (Paragraph 7.7.3) in the sample with respect to the volume of air actually sampled, i.e., ug/m^3. On this basis, a decision is made both on whether to calculate the quantity of each n-alkane equivalent present and on which analytical procedural pathway will be followed. If the total organic content is great enough to warrant continuing the analysis -- >500 ug/m^3 -- a TCO of less than 75 ug/m^3 will require only LC fractionation and gravimetric determinations and IR spectra to be obtained on each fraction. If the TCO is greater than 75 ug/m^3, then the first seven LC fractions of each sample will be reanalyzed using this same gas chromatographic technique.

7.7 Calculations:

7.7.1 **Boiling Point - Retention Time Calibration:** The required data for this calibration are on the chromatogram and on the data sheet. The data reduction is performed as follows:

7.7.1.1 Average the retention times and calculate relative standard deviations for each n-hydrocarbon.

7.7.1.2 Plot average retention times as abscissae versus normal boiling points as ordinates.

7.7.1.3 Draw in calibration curve.

7.7.1.4 Locate and record retention times corresonding to boiling ranges 90-100, 110-140, 140-160, 160-180, 180-200, 200-220, 220-240, 240-260, 260-280, 280-300°C.

7.7.2 **Response-amount calibration:** The required data for this calibration are on the chromatogram and on the data sheet. The data reduction is performed as follows:

7.7.2.1 Average the area responses of each standard and calculate relative standard deviations.

7.7.2.2 Plot response (uv·sec) as ordinate versus ng/uL as abscissa.

7.7.2.3 Draw in the curve. Perform least squares regression and obtain slope (uV·sec·uL/ng).

7.7.3 **Total C7-C16 hydrocarbons analysis:** The required data for this calculation are on the chromatogram and on the data sheet. The data reduction is performed as follows:

7.7.3.1 Sum the areas of all peaks within the retention time range of interest.

7.7.3.2 Convert this area (uV·sec) to ng/uL by dividing by the weight response for n-decane (uV·sec.uL/ng).

7.7.3.3 Multiply this weight by the total concentrate volume (10 mL) to get the weight of the C7-C16 hydrocarbons in the sample.

7.7.3.4 Using the volume of gas sampled or the total weight of sample acquired, convert the result of Step 7.7.3.3 above to ug/m^3.

7.7.3.5 If the value of total C7-C16 hydrocarbons from Step 7.7.3.4 above exceeds 75 ug/m^3, calculate individual hydrocarbon concentrations in accordance with the instructions in Paragraph 7.7.5.5 below.

7.7.4 **Individual C7-C16 n-Alkane Equivalent Analysis:** The required data from the analyses are on the chromatogram and on the data sheet. The data reduction is performed as follows:

7.7.4.1 Sum the areas of peaks in the proper retention time ranges.

7.7.4.2 Convert areas (uV·sec) to ng/uL by dividing by the proper weight response (uV·sec·uL/ng).

7.7.4.3 Multiply each weight by total concentrate volume (10 mL) to get weight of species in each range of the sample.

7.7.4.4 Using the volume of gas sampled on the total weight of sample acquired, convert the result of Step 7.7.4.3 above to ug/m^3.

8.0 QUALITY CONTROL

8.1 Appropriate QC is found in the pertinent procedures throughout the method.

9.0 METHOD PERFORMANCE

9.1 Even relatively comprehensive error propagation analysis is beyond the scope of this procedure. With reasonable care, peak area reproducibility of a standard should be of the order of 1% RSD. The relative standard deviation of the sum of all peaks in a fairly complex waste might be of the order of 5-10%. Accuracy is more difficult to assess. With good analytical technique, accuracy and precision should be of the order of 10-20%.

10.0 REFERENCES

1. Emissions Assessment of Conventional Stationary Combustion Systems: Methods and Procedure Manual for Sampling and Analysis, Interagency Energy/Environmental R&D Program, Industrial Environmental Research Laboratory, Research Triangle Park, NC 27711, EPA-600/7-79-029a, January 1979.

METHOD 0011

SAMPLING FOR SELECTED ALDEHYDE AND KETONE EMISSIONS FROM STATIONARY SOURCES

1.0 SCOPE AND APPLICATION

1.1 This method is applicable to the determination of Destruction and Removal Efficiency (DRE) of the analytes listed in the following table:

Analyte	CAS No.[a]
Formaldehyde	50-00-0
Acetaldehye	75-07-0
Acetophenone	98-86-2
Isophorone	78-59-1
Propionaldehyde	123-38-6

[a] Chemical Abstract Service Registry Number

This method has been applied specifically to the above analytes. Many laboratories have extended method application to other aldehydes and ketones. This method is possibly applicable to other aldehydes and ketones from stationary sources as specified in the regulations. However, this method is not applicable to quinone (CAS No. 106-51-4), acrolein (CAS No. 107-02-08), methyl ethyl ketone (CAS No. 78-93-3), and methyl isobutyl ketone (CAS No. 108-10-1).

1.2 The detection limit for a 30 ft^3 (849 L) sample over a 1 hour sampling period may be as low as 10 ppbv for acetophenone and isophorone, 60 ppbv for propionaldehyde, 40 ppbv for acetaldehyde, and 90 ppbv for formaldehyde. Because the derivatization reaction is based on the formation of an equilibrium state between reactants and products, for some compounds quantitative recoveries may not be achieved until the concentration exceeds 200 ppbv.

1.3 This method is restricted to use by, or under the close supervision of, analysts experienced in sampling organic compounds in air. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

Gaseous and particulate pollutants are withdrawn isokinetically from an emission source and are collected in aqueous acidic 2,4-dinitrophenylhydrazine. Formaldehyde present in the emissions reacts with the 2,4-dinitrophenylhydrazine to form the formaldehyde dinitrophenylhydrazone derivative. The dinitrophenylhydrazone derivative is extracted, solvent-exchanged, concentrated, and then analyzed by high performance liquid chromatography (HPLC) according to Method 8315 or other appropriate technique.

3.0 INTERFERENCES

3.1 A decomposition product of 2,4-dinitrophenylhydrazine, 2,4-dinitroaniline, can be an analytical interferant if concentrations are high. The 2,4-dinitroaniline can coelute with the 2,4-dinitrophenylhydrazone of formaldehyde under the high performance liquid chromatography conditions used for the analysis. High concentrations of highly oxygenated compounds, especially acetone, that have the same retention time or nearly the same retention time as the dinitrophenylhydrazone of formaldehyde, and that also absorb at 360 nm, will interfere with the analysis.

3.2 Formaldehyde, acetone, and 2,4-dinitroaniline contamination of the aqueous acidic 2,4-dinitrophenylhydrazine (DNPH) reagent is frequently encountered. The reagent must be prepared within five days of use in the field and must be stored in an uncontaminated environment both before and after sampling, in order to minimize blank problems. Some concentration of acetone contamination is unavoidable, because acetone is ubiquitous in laboratory and field operations. However, the acetone contamination must be minimized.

3.3 Dimethylolurea creates a slight positive interference; and hexamethylenetetramine and paraformaldehyde significantly interfere with the determination of formaldehyde. These compounds can decompose in the acidic reagent used to collect the sample to form formaldehyde;

3.4 Tolualdehyde interferes with the determination of acetophenone because they coelute chromatographically;

3.5 High levels of nitrogen dioxide can interfere by consuming all of the reagent.

4.0 APPARATUS AND MATERIALS

4.1 This sampling train configuration is adapted from Method 5 (see Ref. 1) procedures. The sampling train consists of the following components: Probe nozzle, pitot tube, differential pressure gauge, metering system, barometer, and gas density determination equipment. A schematic of the sampling train is shown in Figure 1.

4.1.1 Probe Nozzle - The probe nozzle shall be quartz or glass with sharp, tapered (30° angle) leading edge. The taper shall be on the outside to preserve a constant inner diameter. The nozzle shall be buttonhook or elbow design. A range of nozzle sizes suitable for isokinetic sampling should be available in increments of 0.16 cm (1/16 in.), e.g., 0.32 to 1.27 cm (1/8 to ½ in.), or larger if higher volume sampling trains are used. Each nozzle shall be calibrated according to the procedures outlined in Sec. 8.1.

4.1.2 Probe Liner - Borosilicate glass or quartz shall be used for the probe liner. The tester should not allow the temperature in the probe to exceed 120 ±14°C (248 ±25°F).

4.1.3 Pitot Tube - The pitot tube shall be Type S or any other appropriate device. The Type S pitot tube shall be made of metal tubing (e.g., stainless steel). It is recommended that the external tubing diameter be between 0.48 and 0.95 cm. There shall be an equal distance from the base of each leg to its face-opening plane; it is recommended that this distance be between 1.05 and 1.50 times the external tubing diameter. The face openings of the pitot tube shall, preferably, be aligned but slight misalignments of the openings are permissible. The

Type S pitot tube assembly shall have a known coefficient, determined as outlined in Method 2 (see Ref. 1). The pitot tube shall be attached to the probe to allow constant monitoring of the stack gas velocity. The impact (high pressure) opening plane of the pitot tube shall be even with or above the nozzle entry plane (see Method 2) during sampling.

4.1.4 Differential Pressure Gauge - The differential pressure gauge shall be an inclined manometer or equivalent device as described in Method 2. One manometer shall be used for velocity-head readings and the other for orifice differential pressure readings.

4.1.5 Impingers - The sampling train requires a minimum of five impingers, connected as shown in Figure 1, with ground glass (or equivalent) vacuum-tight fittings. For the first, third, fourth, and fifth impingers, use the Greenburg-Smith design, modified by replacing the tip with a 1.27 cm (½ in) inside diameter glass tube extending to 1.27 cm (½ in.) from the bottom of the flask. For the second impinger, use a Greenburg-Smith impinger with the standard tip. Place a thermometer capable of measuring temperature to within 1°C (2°F) at the outlet of the fifth impinger for monitoring purposes.

4.1.6 Metering System - The necessary components of the metering system are a vacuum gauge, leak-free pump, thermometers capable of measuring temperature within 3°C (5.4°F), dry-gas meter capable of measuring volume to within 1%, and related equipment as shown in Figure 1. At a minimum, the pump should be capable of 4 cfm free flow, and the dry gas meter should have a recording capacity of 0-999.9 cu ft with a resolution of 0.005 cu ft. Other metering systems may be used which are capable of maintaining sample volumes to within 2%. The metering system may be used in conjunction with a pitot tube to enable checks of isokinetic sampling rates.

4.1.7 Barometer - The barometer may be mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby National Weather Service Station, in which case the station value (which is the absolute barometric pressure) is requested and an adjustment for elevation differences between the weather station and sampling point is applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase (vice versa for elevation decrease).

4.1.8 Gas Density Determination Equipment - The gas density determination equipment includes a temperature sensor and pressure gauge (as described in Method 2) and gas analyzer, if necessary (an Orsat of Fyrite type combustion gas analyzer, or equivalent. For analyzer maintenance and operation procedures, follow the instructions recommended by the manufacturer). The temperature sensor ideally should be permanently attached to the pitot tube or sampling probe in a fixed configuration such that the tip of the sensor extends beyond the leading edge of the probe sheath and does not touch any metal. Alternatively, the sensor may be attached just prior to use in the field. Note, however, that if the temperature sensor is attached in the field, the sensor must be placed in an interference-free arrangement with respect to the Type S pitot tube openings (see Method 2). As a second alternative, if a difference of no more than 1% in the average velocity measurement is to be introduced, the temperature gauge need not be attached to the probe or pitot tube.

4.2 Sample Recovery

4.2.1 Probe Liner - Probe nozzle and brushes; Teflon® bristle brushes with stainless steel wire handles are required. The probe brush shall have extensions of stainless steel,

Teflon®, or inert material at least as long as the probe. The brushes shall be properly sized and shaped to brush out the probe liner, the probe nozzle, and the impingers.

4.2.2 Wash Bottles - Three wash bottles are required. Teflon® or glass wash bottles are recommended. Polyethylene wash bottles should not be used because organic contaminants may be extracted by exposure to the organic solvents used for sample recovery.

4.2.3 Graduated Cylinder and/or Balance - A graduated cylinder or balance is required to measure condensed water to the nearest 1 mL or 1 g. Graduated cylinders shall have divisions not greater than 2 mL. Laboratory balances capable of weighing to ±0.5 g are required.

4.2.4 Amber Glass Storage Containers - One-liter wide-mouth amber flint glass bottles with Teflon®-lined caps are required to store impinger water samples. The bottles must be sealed with Teflon® tape.

4.2.5 Rubber Policeman and Funnel - A rubber policeman and funnel are required to aid in the transfer of materials into and out of containers in the field.

4.3 Reagent Preparation

4.3.1 Bottles/Caps - Amber 1 - 4 L bottles with Teflon®-lined caps are required for storing cleaned DNPH solution. Additional 4-L bottles are required to collect waste organic solvents.

4.3.2 Large Glass Container - At least one large glass (8 to 16 L) is required for mixing the aqueous acidic DNPH solution.

4.3.3 Stir Plate/Large Stir Bars/Stir Bar Retriever - A magnetic stir plate and large stir bar are required for the mixing of the aqueous acidic DNPH solution. A stir bar retriever is needed for removing the stir bar from the large container holding the DNPH solution.

4.3.4 Buchner Filter/Filter Flask/Filter Paper - A large filter flask (2-4 L) with a buchner filter, appropriate rubber stopper, filter paper, and connecting tubing are required for filtering the aqueous acidic DNPH solution prior to cleaning.

4.3.5 Separatory Funnel - At least one large separatory funnel (2 L) is required for cleaning the DNPH prior to use.

4.3.6 Beakers - Beakers (150 mL, 250 mL, and 400 mL) are useful for holding/measuring organic liquids when cleaning the aqueous acidic DNPH solution and for weighing DNPH crystals.

4.3.7 Funnels - At least one large funnel is needed for pouring the aqueous acidic DNPH into the separatory funnel.

4.3.8 Graduated Cylinders - At least one large graduated cylinder (1 to 2 L) is required for measuring organic-free reagent water and acid when preparing the DNPH solution.

4.3.9 Top-loading Balance - A one-place top loading balance is needed for weighing out the DNPH crystals used to prepare the aqueous acidic DNPH solution.

4.3.10 Spatulas - Spatulas are needed for weighing out DNPH when preparing the aqueous DNPH solution.

4.4 Crushed Ice - Quantities of crushed ice ranging from 10-50 lb may be necessary during a sampling run, depending upon ambient temperature. Samples which have been taken must be stored and shipped cold; sufficient ice for this purpose must be allowed.

5.0 REAGENTS

5.1 Reagent Grade Chemicals - Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Organic-free Reagent Water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One.

5.3 Silica Gel - Silica gel shall be indicating type, 6-16 mesh. If the silica gel has been used previously, dry at 175°C (350°F) for 2 hours before using. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used.

5.4 2,4-Dinitrophenylhydrazine (DNPH), $[2,4\text{-}(0_2N)_2C_6H_3]NHNH_2$ - The quantity of water may vary from 10 to 30%.

5.4.1 The 2,4-dinitrophenylhydrazine reagent must be prepared in the laboratory within five days of sampling use in the field. Preparation of DNPH can also be done in the field, with consideration of appropriate procedures required for safe handling of solvent in the field. When a container of prepared DNPH reagent is opened in the field, the contents of the opened container should be used within 48 hours. All laboratory glassware must be washed with detergent and water and rinsed with water, methanol, and methylene chloride prior to use.

NOTE: DNPH crystals and DNPH solution are potential carcinogens and should be handled with plastic gloves at all times, with prompt and extensive use of running water in case of skin exposure.

5.4.2 Preparation of Aqueous Acidic DNPH Derivatizing Reagent - Each batch of DNPH reagent should be prepared and purified within five days of sampling, according to the procedure described below.

NOTE: Reagent bottles for storage of cleaned DNPH derivatizing solution must be rinsed with acetonitrile and dried before use. Baked glassware is not essential for preparation of DNPH reagent. The glassware must not be rinsed with acetone or an unacceptable concentration of acetone contamination will be introduced. If field preparation of DNPH is performed, caution must be exercised in avoiding acetone contamination.

5.4.2.1 Place an 8 L container under a fume hood on a magnetic stirrer. Add a large stir bar and fill the container half full of organic-free reagent water. Save the

empty bottle from the organic-free reagent water. Start the stirring bar and adjust the stir rate to be as fast as possible. Using a graduated cylinder, measure 1.4 L of concentrated hydrochloric acid. Slowly pour the acid into the stirring water. Fumes may be generated and the water may become warm. Weigh the DNPH crystals to ±0.1 g (see Table 1 for approximate amounts) and add to the stirring acid solution. Fill the 8 L container to the 8 L mark with organic-free reagent water and stir overnight. If all of the DNPH crystals have dissolved overnight, add additional DNPH and stir for two more hours. Continue the process of adding DNPH with additional stirring until a saturated solution has been formed, as evidenced by the presence of visible crystals after continued stirring. Filter the DNPH solution using vacuum filtration. Gravity filtration may be used, but a much longer time is required. Store the filtered solution in an amber bottle at room temperature.

5.4.2.2 Within five days of proposed use, place about 1.6 L of the DNPH reagent in a 2 L separatory funnel. Add approximately 200 mL of methylene chloride and stopper the funnel. Wrap the stopper of the funnel with paper towels to absorb any leakage. Invert and vent the funnel. Then shake vigorously for 3 minutes. Initially, the funnel should be vented frequently (every 10 - 15 seconds). After the layers have separated, discard the lower (organic) layer.

5.4.2.3 Extract the DNPH a second time with methylene chloride and finally with cyclohexane. When the cyclohexane layer has separated from the DNPH reagent, the cyclohexane layer will be the top layer in the separatory funnel. Drain the lower layer (the cleaned extracted DNPH reagent solution) into an amber bottle that has been rinsed with acetonitrile and allowed to dry.

5.4.3 DNPH Reagent Check - Take two aliquots of the extracted DNPH reagent. The size of the aliquots is dependent upon the exact sampling procedure used, but 100 mL is reasonably representative. Analyze one aliquot of the reagent according to Sec. 7 of Method 8315 as a Quality Control check to ensure that the background in the reagent is acceptable for field use. Save the other aliquot of aqueous acidic DNPH for use as a method blank when the analysis is performed. The reagent is acceptable for use if the background meets the AIC (Acceptable Impurity Concentration) as specified in Sec. 5.4.5.

5.4.4 Shipment to the Field - Tightly cap the bottle containing extracted DNPH reagent using a Teflon®-lined cap. Seal the bottle with Teflon® tape. After the bottle is labeled, the bottle may be placed in a friction-top can (paint can or equivalent) containing a 1-2 inch layer of granulated charcoal and stored at ambient temperature until use.

5.4.4.1 If the DNPH reagent has passed the Quality Control criteria, the reagent may be packaged to meet necessary shipping requirements and sent to the sampling area. If the Quality Control criteria are not met, the reagent solution may be re-extracted or the solution may be re-prepared and the extraction sequence repeated.

5.4.4.2 If the DNPH reagent is not used in the field within five days of extraction, an aliquot may be taken and analyzed as described in Sec. 7 of Method 8315. If the reagent meets the Quality Control requirements, the reagent may be used. If the reagent does not meet the Quality Control requirements, the reagent must be discarded and new reagent must be prepared and tested.

5.4.5 Calculation of Acceptable Concentrations of Impurities in DNPH Reagent - The acceptable impurity concentration (AIC, µg/mL) is calculated from the expected analyte concentration in the sampled gas (EAC, ppbv), the volume of air that will be sampled at standard conditions (SVOL, L), the formula weight of the analyte (FW, g/mol), and the volume of DNPH reagent that will be used in the impingers (RVOL, mL):

$$AIC = 0.1 \times [EAC \times SVOL \times FW/24.4 \times (FW + 180)/FW](RVOL/1{,}000)$$

where:

0.1 is the acceptable contaminant concentration,
24.4 is a factor relating ppbv to g/L,
180 is a factor relating underivatized to derivatized analyte, and
1,000 is a unit conversion factor.

5.4.6 Disposal of Excess DNPH Reagent - Excess DNPH reagent may be returned to the laboratory and recycled or treated as aqueous waste for disposal purposes. 2,4-Dinitrophenylhydrazine is a flammable solid when dry, so water should not be evaporated from the solution of the reagent.

5.5 Field Spike Standard Preparation - To prepare a formaldehyde field spiking standard at 4010 mg/L, use a 500 µL syringe to transfer 0.5 mL of 37% by weight of formaldehyde (401 g/L) to a 50 mL volumetric flask containing approximately 40 mL of methanol. Dilute to 50 mL with methanol.

5.6 Hydrochloric Acid, HCl - Reagent grade hydrochloric acid (approximately 12N) is required for acidifying the aqueous DNPH solution.

5.7 Methylene Chloride, CH_2Cl_2 - Methylene chloride (suitable for residue and pesticide analysis, GC/MS, HPLC, GC, Spectrophotometry or equivalent) is required for cleaning the aqueous acidic DNPH solution, rinsing glassware, and recovery of sample trains.

5.8 Cyclohexane, C_6H_{12} - Cyclohexane (HPLC grade) is required for cleaning the aqueous acidic DNPH solution.

NOTE: Do not use spectroanalyzed grades of cyclohexane if this sampling methodology is extended to aldehydes and ketones with four or more carbon atoms.

5.9 Methanol, CH_3OH - Methanol (HPLC grade or equivalent) is necessary for rinsing glassware.

5.10 Acetonitrile, CH_3CN - Acetonitrile (HPLC grade or equivalent) is required for rinsing glassware.

5.11 Formaldehyde, HCHO - Formaldehyde (analytical reagent grade, or equivalent) is required for preparation of standards. If other aldehydes or ketones are used, analytical reagent grade, or equivalent, is required.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Because of the complexity of this method, field personnel should be trained in and experienced with the test procedures in order to obtain reliable results.

6.2 Laboratory Preparation

6.2.1 All the components shall be maintained and calibrated according to the procedure described in APTD-0576 (Air Pollution Technical Document, see references), unless otherwise specified.

6.2.2 Weigh several 200 to 300 g portions of silica gel in airtight containers to the nearest 0.5 g. Record on each container the total weight of the silica gel plus containers. As an alternative to preweighing the silica gel, it may instead be weighed directly in the impinger or sampling holder just prior to train assembly.

6.3 Preliminary Field Determinations

6.3.1 Select the sampling site and the minimum number of sampling points according to Method 1 (see Ref. 1) or other relevant criteria. Determine the stack pressure, temperature, and range of velocity heads using Method 2. A leak-check of the pitot lines according to Method 2 must be performed. Determine the stack gas moisture content using Approximation Method 4 (see Ref. 1) or its alternatives to establish estimates of isokinetic sampling-rate settings. Determine the stack gas dry molecular weight, as described in Method 2. If integrated Method 3 (see Ref. 1) sampling is used for molecular weight determination, the integrated bag sample shall be taken simultaneously with, and for the same total length of time as, the sample run.

6.3.2 Select a nozzle size based on the range of velocity heads so that it is not necessary to change the nozzle size in order to maintain isokinetic sampling rates below 28 L/min (1.0 cfm). During the run, do not change the nozzle. Ensure that the proper differential pressure gauge is chosen for the range of velocity heads encountered (see Sec. 2 of Method 2).

6.3.3 Select a suitable probe liner and probe length so that all traverse points can be sampled. For large stacks, to reduce the length of the probe, consider sampling from opposite sides of the stack.

6.3.4 A minimum of 45 ft^3 of sample volume is required for the determination of the Destruction and Removal Efficiency (DRE) of formaldehyde from incineration systems (45 ft^3 is equivalent to one hour of sampling at 0.75 dscf). Additional sample volume shall be collected as necessitated by the capacity of the DNPH reagent and analytical detection limit constraints. To determine the minimum sample volume required, refer to sample calculations in Sec. 10.0.

6.3.5 Determine the total length of sampling time needed to obtain the identified minimum volume by comparing the anticipated average sampling rate with the volume requirement. Allocate the same time to all traverse points defined by Method 1. To avoid timekeeping errors, the length of time sampled at each traverse point should be an integer or an integer plus 0.5 min.

6.3.6 In some circumstances (e.g., batch cycles) it may be necessary to sample for shorter times at the traverse points and to obtain smaller gas-volume samples. In these cases, careful documentation must be maintained in order to allow accurate calculation of concentrations.

6.4 Preparation of Collection Train

6.4.1 During preparation and assembly of the sampling train, keep all openings where contamination can occur covered with Teflon® film or aluminum foil until just prior to assembly or until sampling is about to begin.

NOTE: Appendix A at the end of this procedure contains guidance on the addition of a filter as a check on the survival of particulate material through the impinger system. This filter can be added to the impinger train either after the second impinger or after the third impinger.

6.4.2 Place 200 mL of purified DNPH reagent in the first impinger and 100 mL of reagent in the second and third impingers, and leave the fourth impinger empty. Transfer approximately 200 to 300 g of preweighed silica gel from its container to the fifth impinger. Care should be taken to ensure that the silica gel is not entrained and carried out from the impinger during sampling. Place the silica gel container in a clean place for later use in the sample recovery. Alternatively, the weight of the silica gel plus impinger may be determined to the nearest 0.5 g and recorded.

6.4.3 With a glass or quartz liner, install the selected nozzle using a Viton-A O-ring when stack temperatures are less than 260°C (500°F) and a woven glass-fiber gasket when temperatures are higher. See APTD-0576 (Rom, 1972) for details. Other connecting systems utilizing either 316 stainless steel or Teflon® ferrules may be used. Mark the probe with heat-resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point.

6.4.4 Assemble the train as shown in Figure 1. During assembly, do not use any silicone grease on ground-glass joints upstream of the impingers. Use Teflon® tape, if required. A very light coating of silicone grease may be used on ground-glass joints downstream of the impingers, but the silicone grease should be limited to the outer portion (see APTD-0576) of the ground-glass joints to minimize silicone grease contamination. If necessary, Teflon® tape may be used to seal leaks. Connect all temperature sensors to an appropriate potentiometer/display unit. Check all temperature sensors at ambient temperature.

6.4.5 Place crushed ice all around the impingers.

6.4.6 Turn on and set the probe heating system at the desired operating temperature. Allow time for the temperature to stabilize.

6.5 Leak-Check Procedures

6.5.1 Pre-test Leak Check

6.5.1.1 After the sampling train has been assembled, turn on and set the probe heating system at the desired operating temperature. Allow time for the temperature to

stabilize. If a Viton-A O-ring or other leak-free connection is used in assembling the probe nozzle to the probe liner, leak-check the train at the sampling site by plugging the nozzle and pulling a 381 mm Hg (15 in. Hg) vacuum.

NOTE: A lower vacuum may be used, provided that the lower vacuum is not exceeded during the test.

6.5.1.2 If an asbestos string is used, do not connect the probe to the train during the leak check. Instead, leak-check the train by first attaching a carbon-filled leak check impinger to the inlet and then plugging the inlet and pulling a 381 mm Hg (15 in. Hg) vacuum. (A lower vacuum may be used if this lower vacuum is not exceeded during the test.) Then connect the probe to the train and leak-check at about 25 mm Hg (1 in. Hg) vacuum. Alternatively, leak-check the probe with the rest of the sampling train in one step at 381 mm Hg (15 in. Hg) vacuum. Leakage rates no greater than 4% of the average sampling rate or less than or equal to 0.00057 m^3/min (0.02 cfm), whichever is less, are acceptable.

6.5.1.3 The following leak check instructions for the sampling train described in APTD-0576 and APTD-0581 may be helpful. Start the pump with the fine-adjust valve fully open and coarse-adjust valve completely closed. Partially open the coarse-adjust valve and slowly close the fine-adjust valve until the desired vacuum is reached. Do not reverse direction of the fine-adjust valve, as liquid will back up into the train. If the desired vacuum is exceeded, either perform the leak check at this higher vacuum or end the leak check, as shown below, and start over.

6.5.1.4 When the leak check is completed, first slowly remove the plug from the inlet to the probe. When the vacuum drops to 127 mm (5 in.) Hg or less, immediately close the coarse-adjust valve. Switch off the pumping system and reopen the fine-adjust valve. Do not reopen the fine-adjust valve until the coarse-adjust valve has been closed to prevent the liquid in the impingers from being forced backward into the sampling line and silica gel from being entrained backward into the third impinger.

6.5.2 Sampling Run Leak Check

6.5.2.1 If, during the sampling run, a component change (i.e., impinger) becomes necessary, a leak check shall be conducted immediately after the interruption of sampling and before the change is made. The leak check shall be done according to the procedure described in Sec. 6.5.1, except that it shall be done at a vacuum greater than or equal to the maximum value recorded up to that point in the test. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable. If a higher leakage rate is obtained, the tester must void the sampling run.

NOTE: Any correction of the sample volume by calculation reduces the integrity of the pollutant concentration data generated and must be avoided.

6.5.2.2 Immediately after a component change and before sampling is reinitiated, a leak check similar to a pre-test leak check must also be conducted.

6.5.3 Post-test Leak Check - A leak check is mandatory at the conclusion of each sampling run. The leak check shall be done with the same procedures as the pre-test leak check, except that the post-test leak check shall be conducted at a vacuum greater than or equal to the maximum value reached during the sampling run. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable. If, however, a higher leakage rate is obtained, the tester shall record the leakage rate and void the sampling run.

6.6 Sampling Train Operation

6.6.1 During the sampling run, maintain an isokinetic sampling rate to within 10% of true isokinetic, below 28 L/min (1.0 cfm). Maintain a temperature around the probe of 120°C (248° ±25°F).

6.6.2 For each run, record the data on a data sheet such as the one shown in Figure 2. Be sure to record the initial dry-gas meter reading. Record the dry-gas meter readings at the beginning and end of each sampling time increment, when changes in flow rates are made, before and after each leak check, and when sampling is halted. Take other readings required by Figure 2 at least once at each sample point during each time increment and additional readings when significant adjustments (20% variation in velocity head readings) necessitate additional adjustments in flow rate. Level and zero the manometer. Because the manometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse.

6.6.3 Clean the stack access ports prior to the test run to eliminate the chance of sampling deposited material. To begin sampling, remove the nozzle cap, verify that the filter and probe heating systems are at the specified temperature, and verify that the pitot tube and probe are properly positioned. Position the nozzle at the first traverse point, with the tip pointing directly into the gas stream. Immediately start the pump and adjust the flow to isokinetic conditions. Nomographs, which aid in the rapid adjustment of the isokinetic sampling rate without excessive computations, are available. These nomographs are designed for use when the Type S pitot tube coefficient is 0.84 ±0.02 and the stack gas equivalent density (dry molecular weight) is equal to 29 ±4. APTD-0576 details the procedure for using the nomographs. If the stack gas molecular weight and the pitot tube coefficient are outside the above ranges, do not use the nomographs unless appropriate steps are taken to compensate for the deviations.

6.6.4 When the stack is under significant negative pressure (equivalent to the height of the impinger stem), take care to close the coarse-adjust valve before inserting the probe into the stack in order to prevent liquid from backing up through the train. If necessary, the pump may be turned on with the coarse-adjust valve closed.

6.6.5 When the probe is in position, block off the openings around the probe and stack access port to prevent nonrepresentative dilution of the gas stream.

6.6.6 Traverse the stack cross section, as required by Method 1, being careful not to bump the probe nozzle into the stack walls when sampling near the walls or when removing or inserting the probe through the access port, in order to minimize the chance of extracting deposited material.

6.6.7 During the test run, make periodic adjustments to keep the temperature around the probe at the proper levels. Add more ice and, if necessary, salt, to maintain a temperature of less than 20°C (68°F) at the silica gel outlet. Also, periodically check the level and zero of the manometer.

6.6.8 A single train shall be used for the entire sampling run, except in cases where simultaneous sampling is required in two or more separate ducts or at two or more different locations within the same duct, or in cases where equipment failure necessitates a change of trains. An additional train or additional trains may also be used for sampling when the capacity of a single train is exceeded.

6.6.9 When two or more trains are used, separate analyses of components from each train shall be performed. If multiple trains have been used because the capacity of a single train would be exceeded, first impingers from each train may be combined, and second impingers from each train may be combined.

6.6.10 At the end of the sampling run, turn off the coarse-adjust valve, remove the probe and nozzle from the stack, turn off the pump, record the final dry gas meter reading, and conduct a post-test leak check. Also, leak check the pitot lines as described in Method 2. The lines must pass this leak check in order to validate the velocity-head data.

6.6.11 Calculate percent isokinetic variation (see Method 5) to determine whether the run was valid or another test should be made.

7.0 SAMPLE RECOVERY AND PREPARATION FOR ANALYSIS

7.1 Preparation

7.1.1 Proper cleanup procedure begins as soon as the probe is removed from the stack at the end of the sampling period. Allow the probe to cool. When the probe can be handled safely, wipe off all external particulate matter near the tip of the probe nozzle and place a cap over the tip to prevent losing or gaining particulate matter. Do not cap the probe tip tightly while the sampling train is cooling because a vacuum will be created, drawing liquid from the impingers back through the sampling train.

7.1.2 Before moving the sampling train to the cleanup site, remove the probe from the sampling train and cap the open outlet, being careful not to lose any condensate that might be present. Remove the umbilical cord from the last impinger and cap the impinger. If a flexible line is used, let any condensed water or liquid drain into the impingers. Cap off any open impinger inlets and outlets. Ground glass stoppers, Teflon® caps, or caps of other inert materials may be used to seal all openings.

7.1.3 Transfer the probe and impinger assembly to an area that is clean and protected from wind so that the chances of contaminating or losing the sample are minimized.

7.1.4 Inspect the train before and during disassembly, and note any abnormal conditions.

7.1.5 Save a portion of all washing solution (methylene chloride, water) used for cleanup as a blank. Transfer 200 mL of each solution directly from the wash bottle being used and place each in a separate, pre-labeled sample container.

7.2 Sample Containers

7.2.1 Container 1 - Probe and Impinger Catches. Using a graduated cylinder, measure to the nearest mL, and record the volume of the solution in the first three impingers. Alternatively, the solution may be weighed to the nearest 0.5 g. Transfer the impinger solution from the graduated cylinder into the amber flint glass bottle. Taking care that dust on the outside of the probe or other exterior surfaces does not get into the sample, clean all surfaces to which the sample is exposed (including the probe nozzle, probe fitting, probe liner, first impinger, and impinger connector) with methylene chloride. Use less than 500 mL for the entire wash (250 mL would be better, if possible). Add the washings to the sample container.

7.2.1.1 Carefully remove the probe nozzle and rinse the inside surface with methylene chloride from a wash bottle. Brush with a Teflon® bristle brush, and rinse until the rinse shows no visible particles or yellow color, after which make a final rinse of the inside surface. Brush and rinse the inside parts of the Swagelok fitting with methylene chloride in a similar way.

7.2.1.2 Rinse the probe liner with methylene chloride. While squirting the methylene chloride into the upper end of the probe, tilt and rotate the probe so that all inside surfaces will be wetted with methylene chloride. Let the methylene chloride drain from the lower end into the sample container. The tester may use a funnel (glass or polyethylene) to aid in transferring the liquid washes to the container. Following the rinse with a Teflon® brush. Hold the probe in an inclined position, and squirt methylene chloride into the upper end as the probe brush is being pushed with a twisting action through the probe. Hold the sample container underneath the lower end of the probe, and catch any methylene chloride, water, and particulate matter that is brushed from the probe. Run the brush through the probe three times or more. Rinse the brush with methylene chloride or water, and quantitatively collect these washings in the sample container. After the brushings, make a final rinse of the probe as described above.

NOTE: Between sampling runs, brushes must be kept clean and free from contamination.

7.2.1.3 Rinse the inside surface of each of the first three impingers (and connecting tubing) three separate times. Use a small portion of methylene chloride for each rinse. Water will be required for the recovery of the impingers in addition to the specified quantity of methylene chloride. There will be at least two phases in the impingers. This two-phase mixture does not pour well, and a significant amount of the impinger catch will be left on the walls. The use of water as a rinse makes the recovery quantitative. Make a final rinse of each surface, using both methylene chloride and water.

7.2.1.4 After all methylene chloride and water washings and particulate matter have been collected in the sample container, tighten the lid so that solvent, water, and DNPH reagent will not leak out when the container is shipped to the laboratory. Mark the height of the fluid level to determine whether leakage occurs during transport. Seal the container with Teflon® tape. Label the container clearly to identify its contents.

7.2.1.5 If the first two impingers are to be analyzed separately to check for breakthrough, separate the contents and rinses of the two impingers into individual containers. Care must be taken to avoid physical carryover from the first impinger to the second. The formaldehyde hydrazone is a solid which floats and froths on top of the impinger solution. Any physical carryover of collected moisture into the second impinger will invalidate a breakthrough assessment.

7.2.2 Container 2 - Sample Blank. Prepare a sample blank by using an amber flint glass container and adding a volume of DNPH reagent and methylene chloride equal to the total volume in Container 1. Process the blank in the same manner as Container 1.

7.2.3 Container 3 - Silica Gel. Note the color of the indicating silica gel to determine whether it has been completely spent and make a notation of its condition. The impinger containing the silica gel may be used as a sample transport container with both ends sealed with tightly fitting caps or plugs. Ground-glass stoppers or Teflon® caps may be used. The silica gel impinger should then be labeled, covered with aluminum foil, and packaged on ice for transport to the laboratory. If the silica gel is removed from the impinger, the tester may use a funnel to pour the silica gel and a rubber policeman to remove the silica gel from the impinger. It is not necessary to remove the small amount of dust particles that may adhere to the impinger wall and are difficult to remove. Since the gain in weight is to be used for moisture calculations, do not use water or other liquids to transfer the silica gel. If a balance is available in the field, the spent silica gel (or silica gel plus impinger) may be weighed to the nearest 0.5 g.

7.2.4 Sample containers should be placed in a cooler, cooled by although not in contact with ice. Sample containers must be placed vertically and, since they are glass, protected from breakage during shipment. Samples should be cooled during shipment so they will be received cold at the laboratory.

7.3 The dinitrophenylhydrazone derivative is then analyzed by high performance liquid chromatography (HPLC) (Method 8315) or other appropriate technique.

8.0 CALIBRATION

8.1 Probe Nozzle - Probe nozzles shall be calibrated before their initial use in the field. Using a micrometer, measure the inside diameter of the nozzle to the nearest 0.025 mm (0.001 in.). Make measurements at three separate places across the diameter and obtain the average of the measurements. The difference between the high and low numbers shall not exceed 0.1 mm (0.004 in.). When the nozzles become nicked or corroded, they shall be replaced and calibrated before use. Each nozzle must be permanently and uniquely identified.

8.2 Pitot Tube - The Type S pitot tube assembly shall be calibrated according to the procedure outlined in Method 2, or assigned a nominal coefficient of 0.84 if it is not visibly nicked or corroded and if it meets design and intercomponent spacing specifications.

8.3 Metering System

8.3.1 Before its initial use in the field, the metering system shall be calibrated according to the procedure outlined in APTD-0576. Instead of physically adjusting the dry-gas meter dial readings to correspond to the wet-test meter readings, calibration factors may be used to

correct the gas meter dial readings mathematically to the proper values. Before calibrating the metering system, it is suggested that a leak check be conducted. For metering system having diaphragm pumps, the normal leak check procedure will not detect leakages within the pump. For these cases, the following leak check procedure will apply: make a ten-minute calibration run at 0.00057 m^3/min (0.02 cfm). At the end of the run, take the difference of the measured wet-test and dry-gas meter volumes and divide the difference by 10 to get the leak rate. The leak rate should not exceed 0.00057 m^3/min (0.02 cfm).

8.3.2 After each field use, check the calibration of the metering system by performing three calibration runs at a single intermediate orifice setting (based on the previous field test). Set the vacuum at the maximum value reached during the test series. To adjust the vacuum, insert a valve between the wet-test meter and the inlet of the metering system. Calculate the average value of the calibration factor. If the calibration has changed by more than 5%, recalibrate the meter over the full range of orifice settings, as outlined in APTD-0576.

8.3.3 Leak Check of Metering System - The portion of the sampling train from the pump to the orifice meter (see Figure 1) should be leak-checked prior to initial use and after each shipment. Leakage after the pump will result in less volume being recorded than is actually sampled. Use the following procedure: Close the main valve on the meter box. Insert a one-hole rubber stopper with rubber tubing attached into the orifice exhaust pipe. Disconnect and vent the low side of the orifice manometer. Close off the low side orifice tap. Pressurize the system to 13 - 18 cm (5 - 7 in.) water column by blowing into the rubber tubing. Pinch off the tubing and observe the manometer for 1 min. A loss of pressure on the manometer indicates a leak in the meter box. Leaks must be corrected.

NOTE: If the dry-gas-meter coefficient values obtained before and after a test series differ by greater than 5%, either the test series must be voided or calculations for test series must be performed using whichever meter coefficient value (i.e., before or after) gives the lower value of total sample volume.

8.4 Probe Heater - The probe heating system must be calibrated before its initial use in the field according to the procedure outlined in APTD-0576. Probes constructed according to APTD-0581 need not be calibrated if the calibration curves in APTD-0576 are used.

8.5 Temperature Gauges - Each thermocouple must be permanently and uniquely marked on the casting. All mercury-in-glass reference thermometers must conform to ASTM E-1 63C or 63F (American Society for Testing and Materials) specifications. Thermocouples should be calibrated in the laboratory with and without the use of extension leads. If extension leads are used in the field, the thermocouple readings at the ambient air temperatures, with and without the extension lead, must be noted and recorded. Correction is necessary if the use of an extension lead produces a change greater than 1.5%.

8.5.1 Impinger and Dry-gas Meter Thermocouples - For the thermocouples used to measure the temperature of the gas leaving the impinger train, a three-point calibration at ice water, room air, and boiling water temperatures is necessary. Accept the thermocouples only if the readings at all three temperatures agree to ±2°C (3.6°F) with those of the absolute value of the reference thermometer.

8.5.2 Probe and Stack Thermocouple - For the thermocouples used to indicate the probe and stack temperatures, a three-point calibration at ice water, boiling water, and hot oil

bath temperatures must be performed. Use of a point at room air temperature is recommended. The thermometer and thermocouple must agree to within 1.5% at each of the calibration points. A calibration curve (equation) may be constructed (calculated) and the data extrapolated to cover the entire temperature range suggested by the manufacturer.

8.6 Barometer - Adjust the barometer initially and before each test series to agree to within ±2.5 mm Hg (0.1 in. Hg) of the mercury barometer or the corrected barometric pressure value reported by a nearby National Weather Service Station (same altitude above sea level).

8.7 Triple-beam or Electronic Balance - Calibrate the balance before each test series, using Class S standard weights. The weights must be within ±0.5% of the standards, or the balance must be adjusted to meet these limits.

9.0 CALCULATIONS

Perform calculations, retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculations.

9.1 Total Formaldehyde - Determine the total formaldehyde in mg, using the following equation:

$$\text{Total mg formaldehyde} = C_d \times V \times DF \times \left[\frac{\text{g/mole aldehyde}}{\text{g/mole DNPH derivative}}\right] \times 10^{-3} \text{ mg/µg}$$

where:

C_d = measured concentration of DNPH-formaldehyde derivative, µg/mL
V = organic extract volume, mL
DF = dilution factor

9.2 Formaldehyde Concentration In Stack Gas - Determine the formaldehyde concentration in the stack gas using the following equation:

$$C_f = K \text{ [total formaldehyde, mg]} / V_{m(std)}$$

where:

K = 35.31 ft^3/m^3 if $V_{m(std)}$ is expressed in English units
= 1.00 m^3/m^3 if $V_{m(std)}$ is expressed in metric units
$V_{m(std)}$ = volume of gas sample as measured by dry gas meter, corrected to standard conditions, dscm (dscf)

9.3 Average Dry Gas Meter Temperature and Average Orifice Pressure Drop are obtained from the data sheet.

9.4 Dry Gas Volume - Calculate $V_{m(std)}$ and adjust for leakage, if necessary, using the equation in Sec. 6 of Method 5.

9.5 Volume of Water Vapor and Moisture Content - Calculate the volume of water vapor and moisture content from Equations 5-2 and 5-3 of Method 5.

10.0 DETERMINATION OF VOLUME TO BE SAMPLED

To determine the minimum sample volume to be collected, use the following sequence of equations.

10.1 From prior analysis of the waste feed, the concentration of formaldehyde (FORM) introduced into the combustion system can be calculated. The degree of destruction and removal efficiency that is required is used to determine the maximum amount of FORM allowed to be present in the effluent. This amount may be expressed as:

$$\text{Max FORM}_i \text{ Mass} = [(WF)(\text{FORM}_i \text{ conc})(100 - \%DRE)] / 100$$

where:

WF = mass flow rate of waste feed per h, g/h (lb/h)
FORM_i = concentration of FORM (wt %) introduced into the combustion process
DRE = percent Destruction and Removal Efficiency required
Max FORM = mass flow rate (g/h [lb/h]) of FORM emitted from the combustion sources

10.2 The average discharge concentration of the FORM in the effluent gas is determined by comparing the Max FORM with the volumetric flow rate being exhausted from the source. Volumetric flow rate data are available as a result of preliminary Method 1 - 4 determinations:

$$\text{Max FORM}_i \text{ conc} = [\text{Max FORM}_i \text{ Mass}] / DV_{eff(std)}$$

where:

$DV_{eff(std)}$ = volumetric flow rate of exhaust gas, dscm (dscf)
FORM_i conc = anticipated concentration of the FORM in the exhaust gas stream, g/dscm (lb/dscf)

10.3 In making this calculation, it is recommended that a safety margin of at least ten be included.

$$[LDL_{FORM} \times 10] / [\text{FORM}_i \text{ conc}] = V_{tbc}$$

where:

LDL_{FORM} = detectable amount of FORM in entire sampling train
V_{tbc} = minimum dry standard volume to be collected at dry-gas meter

10.4 The following analytical detection limits and DNPH Reagent Capacity (based on a total volume of 200 mL in two impingers) must also be considered in determining a volume to be sampled.

11.0 QUALITY CONTROL

11.1 Sampling - See EPA Manual 600/4-77-027b for Method 5 quality control.

11.2 Analysis - The quality assurance program required for this method includes the analysis of field and method blanks, procedure validations, analysis of field spikes, and analysis of reagent checks. The assessment of combustion data and positive identification and quantitation of formaldehyde are dependent on the integrity of the samples received and the precision and accuracy of the analytical methodology. Quality Assurance procedures for this method are designed to monitor the performance of the analytical methodology and to provide the required information to take corrective action if problems are observed in laboratory operations or in field sampling activities.

11.2.1 Field Blanks - Field blanks may be submitted with the samples collected at each sampling site. The field blanks include the sample bottles containing aliquots of sample recovery solvents, methylene chloride and water, and unused DNPH reagent. In the case of results exceeding regulatory limits, field blank data may be useful for convincing the regulatory official that contamination was the cause. This may result in retesting rather than a violation charge. Collection of the field blank is optional but recommended.

11.2.2 Method Blanks - A method blank must be prepared for each set of analytical operations, to evaluate contamination and artifacts that can be derived from glassware, reagents, and sample handling in the laboratory.

11.2.3 Field Spikes - A field spike is performed by introducing 200 µL of the Field Spike Standard into an impinger containing 200 mL of DNPH solution. Standard impinger recovery procedures are followed and the field spike sample is returned to the laboratory for analysis. The field spike is used as a check on field handling and recovery procedures. An aliquot of the field spike standard is retained in the laboratory for derivatization and comparative analysis.

11.2.4 Matrix Spike Sample - In addition to those stack samples necessary for basic data needs, one complete sample (of the same time duration) must be collected for use as a matrix spike sample as described in Sec. 8.0 of Method 8315. This sample must be recovered and shipped in exactly the same manner as the other stack samples. Every effort should be made to ensure that this sample represents the average stack matrix of the sample batch. For example, the matrix spike sample should be taken the same day as the other samples in the group, if at all possible. If it is known or suspected that the stack gas matrix is varying widely during the overall sampling run, it is advisable to take more than one matrix spike sample and composite them.

11.2.5 DNPH Reagent Checks - An aliquot of the extracted DNPH reagent is prepared and analyzed according to the procedure in Sec. 5.4.3 to ensure that the background in the reagent is acceptable for field use.

12.0 METHOD PERFORMANCE

Method performance evaluation - The expected method performance parameters for precision, accuracy, and detection limits are provided in Table 3.

APPENDIX A

ADDITION OF A FILTER TO THE FORMALDEHYDE SAMPLING TRAIN

As a check on the survival of particulate material through the impinger system, a filter can be added to the impinger train either after the second impinger or after the third impinger. Since the impingers are in an ice bath, there is no reason to heat the filter at this point.

Any suitable medium (e.g., paper, organic membrane) may be used for the filter if the material conforms to the following specifications:

1) The filter has at least 95% collection efficiency (<5% penetration) for 3 µm dioctyl phthalate smoke particles. The filter efficiency test shall be conducted in accordance with ASTM standard method D2986-71. Test data from the supplier's quality control program are sufficient for this purpose.

2) The filter has a low aldehyde blank value (<0.015 mg formaldehyde/cm^2 of filter area). Before the test series, determine the average formaldehyde blank value of at least three filters (from the lot to be used for sampling) using the applicable analytical procedures.

Recover the exposed filter into a separate clean container and return the container over ice to the laboratory for analysis. If the filter is being analyzed for formaldehyde, the filter may be recovered into a container or DNPH reagent for shipment back to the laboratory. If the filter is being examined for the presence of particulate material, the filter may be recovered into a clean dry container and returned to the laboratory.

METHOD 0020

SOURCE ASSESSMENT SAMPLING SYSTEM (SASS)

1.0 PRINCIPLE AND APPLICATION

1.1 Principle

1.1.1 Particulate and semivolatile organic materials are withdrawn from a source at a constant rate near isokinetic conditions and are collected in a multicomponent sampling train.

1.1.2 Three heated cyclones and a heated high-efficiency fiber filter remove and collect the particulate material from the sample and a packed bed of porous polymeric resin adsorbs the condensible organic vapors.

1.1.3 Chemical analyses of the sample are conducted to determine the concentration and identity of the semivolatile organic species and gravimetric determinations are performed to approximate particulate emissions.

1.2 Application: This method is applicable to the preparation of semiquantitative estimates (within a factor of three) of the amounts and types of semivolatile organic and particulate materials that are discharged from incineration systems.

2.0 APPARATUS

2.1 Sampling Train: A schematic of the sampling train used in this method is given in Figure 1. This sampling train configuration is that of the Source Assessment Sampling System (SASS), as supplied by the manufacturer. Basic operating and maintenance procedures are described in the "Operating and Service Manual: Source Assessment Sampling System" supplied on purchase of the sampling system (Blake, 1977). Users should refer to this document and adopt, but not limit themselves to, its operating and maintenance procedures. The SASS train components and specifications are detailed below.

2.1.1 **Probe nozzles:** The probe nozzles are constructed of Type 316 seamless stainless steel tubing and have sharp leading edges. The nozzles are a hybrid elbow/buttonhook design, obtainable in diameters ranging from 0.31 to 1.91 cm (1/8 to 3/4 in.), and are interchangeable. Each nozzle should be calibrated according to the procedure outlined in Paragraph 7.2 of this method.

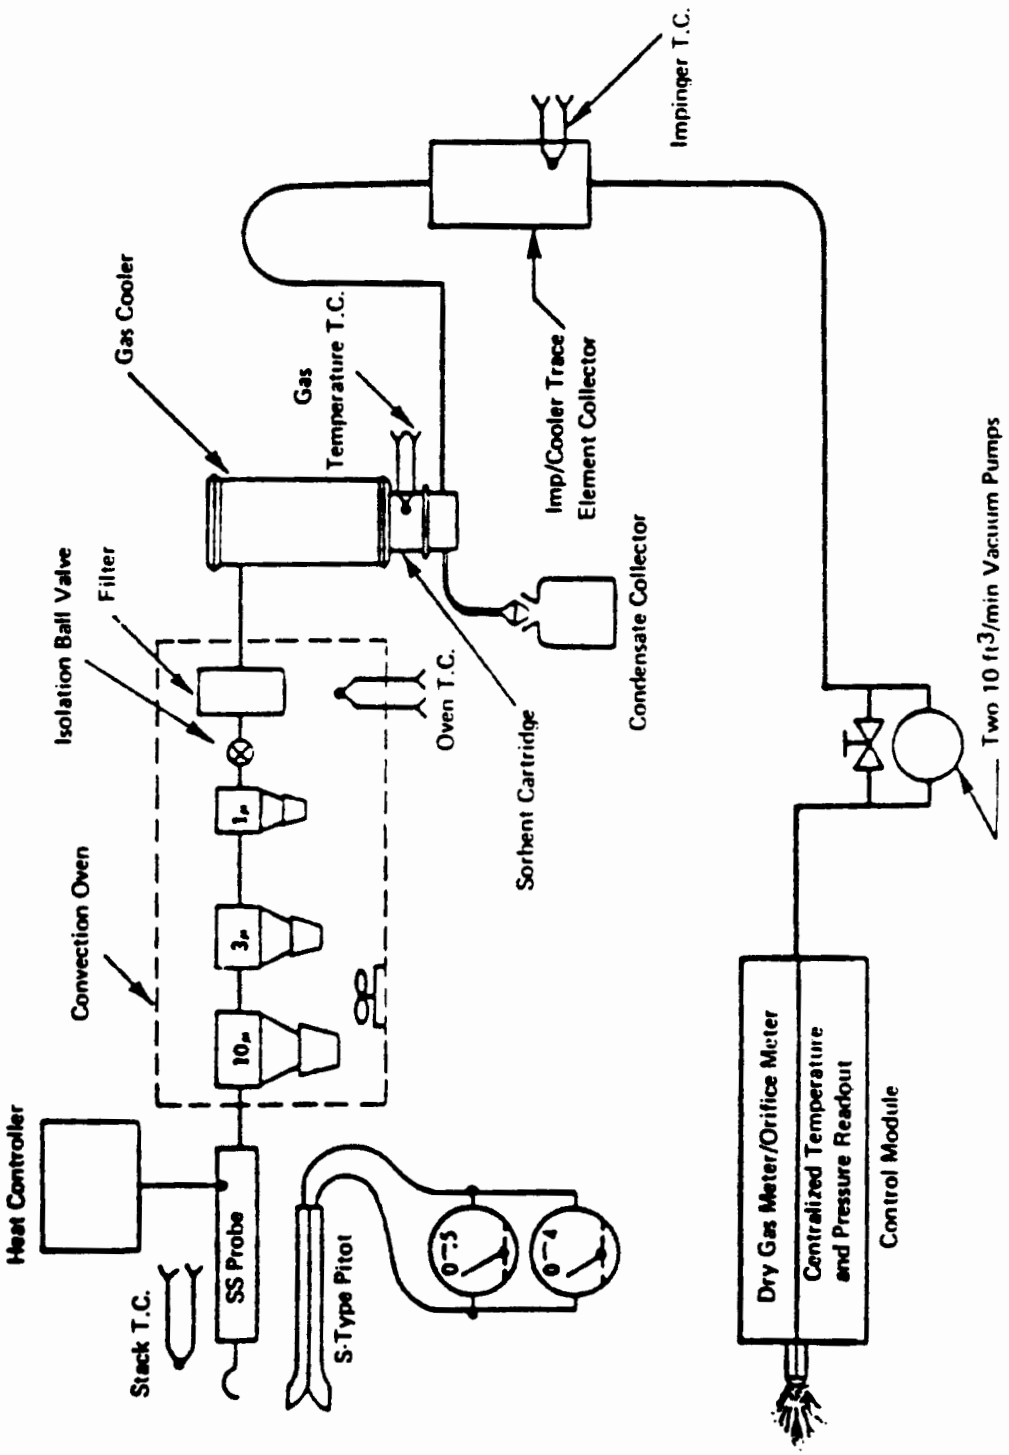

Figure 1. SASS Schematic Diagram.

2.1.2 **Probe Liner:**

2.1.2.1 The probe liner is also constructed of Type 316 seamless stainless steel tubing; attached to the liner is a proportional temperature controller capable of maintaining the liner surface temperature at 204 $\pm$ 20°C (400 $\pm$ 36°F) during sampling. The use of the proportional controller to control the liner surface temperature at the control module is preferred because the oven often cannot be reached for adjustment during sampling.

2.1.2.2 It should be noted that the measurement of the probe liner surface temperature is not an accurate measurement of the internal gas stream temperature, which is the temperature of interest. This source of error is caused by the temperature gradient that exists between the inner and outer walls of the liner. Monitoring of the actual gas stream temperature is impractical with the SASS trains as presently constructed. It is suggested that a one-time calibration be conducted in which the internal gas stream temperature is compared to the liner surface at various temperatures and at the standard SASS flow rate of 4.0 scfm.

2.1.2.3 The probe and probe liner can withstand points up to 370°C (700°F), at which temperature they will soften. However, stack temperatures greater than 288°C (550°F) may result in gas temperatures at the 10-um cyclone inlet greater than the recommended 204°C (400°F) and hence require the use of a special water- or forced-air-cooled probe.

2.1.3 **Pitot tubes:** The pitot tubes are Type S, designed to meet the specifications of EPA Method 2 (see Reference below); these are attached to the probe sheath to allow constant monitoring of the stack gas velocity. The point of attachment to the sheath is such that the impact (high pressure) opening plane of the pitots is level with or above the sampling nozzle entry plane, as required by Method 2, to eliminate nozzle interference in velocity measurements. If calibration is not required, the pitot tubes are assigned a nominal coefficient of 0.84, as described in the calibration section of this method.

2.1.4 **Differential pressure gauges:** Three Magnehelic-type gauges are used. One gauge (0 to 0.5 in. H_2O) monitors the pressure drop across the orifice meter (ΔH_i); the other two gauges (0 to 0.5 and 0 to 4.0 in. H_2O) are connected in parallel and indicate the pressure differential across the pitot tubes used for measuring stack gas velocity.

2.1.5 **Filter holder and filter support:** The filter holder and filter support screen are constructed of Type 316 stainless steel with a

Teflon gasket providing an airtight seal around the circumference. The holder is attached immediately to the outlet of the 1-um cyclone or the cyclone bypass.

2.1.6 **Cyclone/Filter heating system:** The cyclone/filter heating system is an insulated double-walled oven, capable of maintaining the temperature in the area of the cyclones and filter holder around the recommended 204°C (400°F). A chromel-alumel thermocouple for temperature sensing allows feedback control of the temperature to within approximately 10%.

2.1.7 **Cyclone train:** The cyclone train consists of three cyclone separators in series, having nominal particle-size cutoff diameters of 10, 3, and 1 um respectively. The material of construction is Type 316 stainless steel with Teflon gaskets sealing the hoods and collector cups. The compact design of the 10-um cyclone is achieved by incorporating flow-interrupting vanes in the collection cup.

2.1.8 **Organic module:** The organic module consists of a thin-film heat exchanger/gas cooler, a sorbent cartridge, and a condensate collection trap. The temperature of the heat exchanger fluid is regulated by activating an immersion heater or routing the coolant through another heat exchanger in the impinger ice water bath. Water from the impinger bath is continually circulated through the inner reservoir of the gas cooler for additional cooling capacity. The sorbent cartridge encloses the polymeric adsorbent bed in a cylinder covered on both ends by 80-mesh, Type 316 stainless steel wire cloth. The cartridge holds approximately 150 grams of XAD-2 adsorbent resin. Condensed moisture from the gas stream is collected in a reservoir located directly beneath the packed sorbent bed. The drain valve of the reservoir should be coupled with a Teflon line to an appropriately sized (1- to 5-liter) glass storage container, as the capacity of the reservoir will typically be exceeded during a run.

2.1.9 **Impinger train:** The four impingers have a capacity of approximately 3 liters each and are constructed of pyrex glass. The caps are Teflon with stainless steel fittings and the impingers are interconnected by flexible Teflon or stainless steel tubing. The first two impingers are equipped with splash guards to minimize fluid carryover and the last impinger with a thermocouple mounted in the cap for monitoring the impinger train exit gas temperature.

2.1.10 **Pump/Metering system:** Two leak-free vane-type vacuum pumps connected in parallel are used to maintain the 4.0-scfm flow in the sampling system. Vacuum and differential pressure gauges, thermocouples capable of measuring temperature to within 3°C (5.4°F) and a dry gas meter capable of measuring volume to within 2% are supplied as the other necessary components for maintaining isokinetic sampling rates.

2.1.11 **Barometer:** An aneroid barometer, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.5 in. Hg), is required, unless the barometric reading is obtained from a nearby National Weather Station; the station value (i.e., the absolute barometric pressure) must be corrected for elevation differences between the weather station and the sampling point. The corrected value should reflect a decrease of 2.5 mm Hg (0.1 in. Hg) per 30-m (100-ft) elevation increase, and vice versa for elevation decrease. (See Paragraph 7.7).

2.1.12 **Gas density determination apparatus:** The length of a SASS run is typically sufficient to determine the average gas stream density during the run. EPA Method 3 should be consulted for detailed specifications for an integrated fixed gas sampling system. Analysis of the collected samples should be performed with an ORSAT analyzer or a GC/TCD system outfitted specifically for this purpose.

2.1.13 **Calibration/Field preparation log:** For documentation of calibration and preparation procedures, a permanently bound laboratory notebook is recommended, in which carbon copies are made of the data as they are being recorded. The carbon copies should be detachable and used only for separate storage in the test program archives.

2.2 Sample recovery:

2.2.1 **Probe liner brush:** The brush must have nylon bristles, a stainless steel wire handle, and extensions of stainless steel, Teflon, or other inert material. The combined extensions must be equal to or greater than the length of the probe.

2.2.2 **Probe nozzle brush:** The brush must have nylon bristles and a stainless steel wire handle, and be properly sized and shaped for cleaning the inner surfaces of the nozzle.

2.2.3 **Cyclone and filter holder brushes:** The brushes must have nylon bristles and a stainless steel wire handle, and be properly sized for cleaning the inner walls of these components. It is strongly recommended that a separate brush be used for sample recovery from each of these components to avoid cross contamination of one particle size fraction by another.

2.2.4 **Wash bottles:** Three are needed. Teflon or glass is required to avoid contamination of organic solvents; Teflon is preferred because it is unbreakable.

2.2.5 **Glass sample storage containers:** The containers must be chemically resistant, borosilicate glass bottles, 500-mL or 1,000-mL. Screw-cap liners should be Teflon or constructed so as to be leak-free and resistant to chemical attack by organic recovery solvents (narrow-mouth glass bottles have been found to exhibit less tendency toward leakage).

2.2.6 **Petri dishes:** These must be glass and sealed around the circumference with Teflon tape for storage and transport of filter samples.

2.2.7 **Graduated cylinder and triple-beam balance:** to measure condensed water to the nearest 1 mL or 0.5 g. Graduated cylinders must have subdivisions no greater than 2 mL. Equipment made of glass must be used for measuring the volume of any solution that will be subject to organic analysis. Laboratory triple-beam balances must be capable of weighing to ±0.5 g or better.

2.2.8 **High-density linear polyethylene (HDLP) storage containers:** These are used for storage of the impingers.

2.2.9 **Plastic storage containers:** Airtight containers are necessary for storage of silica gel.

2.2.10 **Funnels:** Glass funnels must be used in recovering samples for organic analysis. Glass or plastic funnels may be used in other processes but care must be taken to segregate the two types.

3.0 REAGENTS AND MATERIALS

3.1 Filters: Glass fiber filters, 15.24 cm (6.0 in.) in diameter without organic binder, exhibiting 99.95% efficiency (<0.05% penetration) on 0.3-micron dioctyl phthalate smoke particles, conforming to the specifications outlined in ASTM Standard Method D2986-71. Test data from the supplier's quality control program are sufficient for this purpose. The filter material must also be unreactive to SO_2 and SO_3.

3.2 Adsorbent resin: Porous polymeric resin, XAD-2, is used. The resin must be cleaned prior to use. The resin must not exhibit a blank higher than 4 mg/kg of total chromatographable organics (TCO) prior to use. Once cleaned, the resin should be stored in a wide-mouth amber glass container and the headspace purged with nitrogen to limit exposure to ambient air. Resin should be used within 2 wk of preparation.

3.3 Silica gel: Indicating type, 6 to 16 mesh. If previously used, dry at 175°C (350°F) for 2 hr. New silica gel may be used as received.

3.4 Impinger solutions: Since the impinger solutions are typically used for the determination of gas-stream water-vapor content, Type II water should be used. If specific inorganic species are to be determined (e.g., hydrochloric acid when burning chlorinated organic material), then other appropriate collecting solutions (in the above example, dilute base) must be used.

3.5 Crushed ice: Commercially available. Quantities ranging from 50 to 100 lb may be necessary during a run, depending upon ambient air temperatures.

3.6 Methanol/Methylene chloride: Distilled-in-glass or pesticide-grade methanol and methylene chloride are required.

4.0 SAMPLING PROCEDURE

4.1 Sampling equipment calibration:

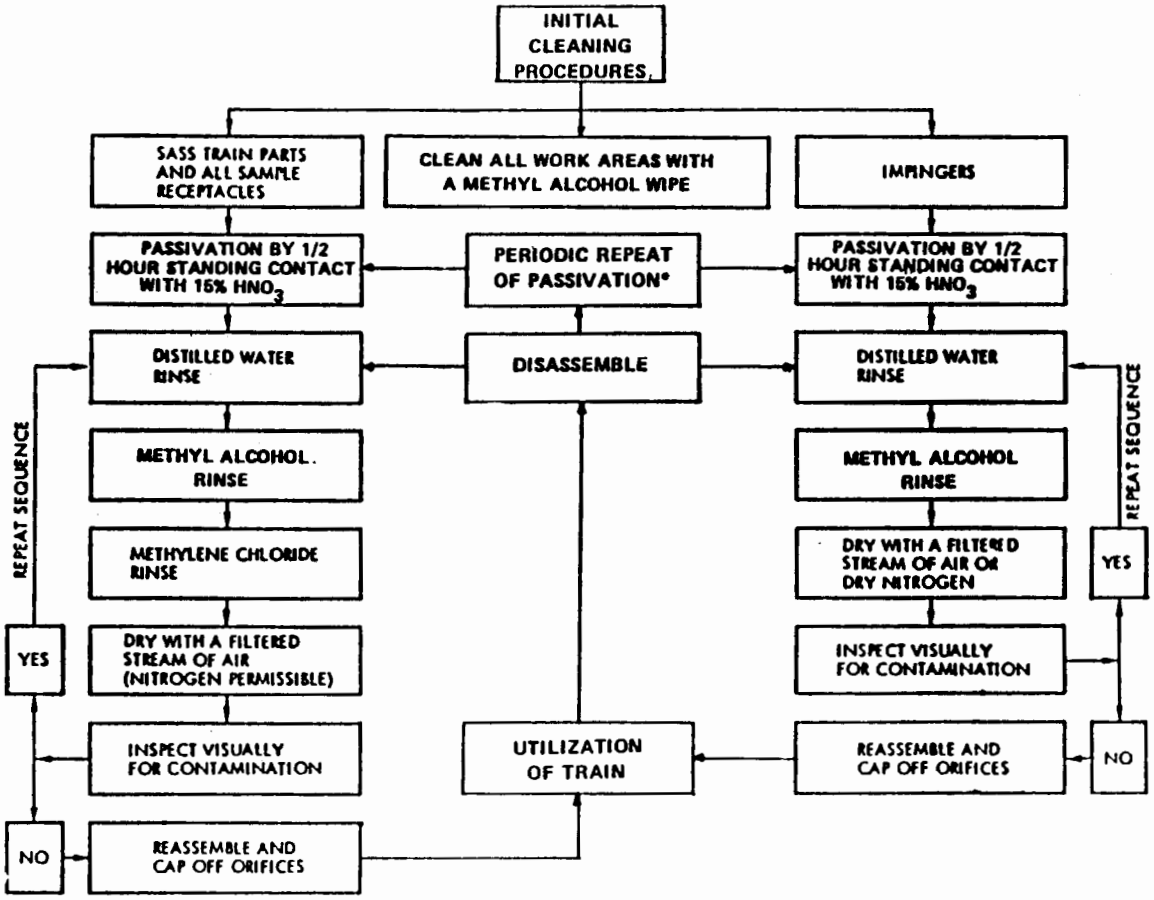
4.1.1 The probe tips, pitot tubes, dry gas meter, thermocouples, and any thermometers must be calibrated before and after each field sampling trip according to the procedures outlined in APTD-0576 (Rom, 1972) and below in Section 7.0. During extended sampling trips where the train will routinely be used more than 10 times, it is strongly recommended that a calibrated orifice, a set of micrometers (Vernier calipers), and a standard mercury-in-glass thermometer accompany the train to verify that the calibrations of the dry gas meter, probe nozzles, and thermocouples, respectively, have not changed significantly (more than ±2%). The aneroid barometer should be calibrated on a daily basis against a mercury barometer when in the laboratory and periodically in the field by consulting the local weather station and correcting for elevation (see Paragraph 7.7).

4.2 Laboratory preparation:

4.2.1 Weigh several 700- to 800-g portions of silica gel in airtight containers to ±0.1 g. Record the weight of the silica gel plus the container on the container and in a field sampling preparation notebook.

4.2.2 Holding with blunt-tipped tweezers, check filters visually against light for irregularities, flaws, or pinhole leaks. Label the shipping containers (glass Petri dishes) and keep the filters in these containers at all times except during sampling and weighing. The filters themselves need not be labeled if strict compliance with the above instruction is ensured. Desiccate the filters in a desiccator over Drierite or silica gel with the Petri dishes open at 20 ± 5.6°C (68 + 10°F) and ambient pressure for at least 24 hr and weigh. Thereafter weigh at 6-hr (minimum) intervals to a constant weight, i.e., previous weight ±0.5 mg; record the weight to the nearest 0.1 mg, along with the date and time, in the field sampling preparation notebook. Alternatively, the filters may be oven-dried at 105°C (220°F) for 2 to 3 hr, desiccated for 2 hr, weighed, and weighed thereafter at 6-hr intervals to a constant weight. During each weighing, the filter must not be exposed to the laboratory atmosphere for longer than 2 min with a relative humidity greater than 50%.

4.2.3 Passivate all SASS train parts and sample storage containers, referring to the procedure that appears in Figure 2, adapted from Level I requirements. Passivation is required of all new train components and sample storage containers before their initial use in the field. Thereafter, passivation should be conducted every 6 months when the frequency of tests is once per month or less, and every 3 months when the



SASS Cleaning Procedures
Source: "IERL-RTP Procedures Manual: Level 1 Environmental Assessment (Second Ed.) EPA-600/7-78-201

Figure 2. SASS Cleaning Procedure

frequency is between once per week and once per month. If testing is more frequent, passivation should be conducted proportionately more often. Whenever corrosion has occurred, the corrosion must be removed and the passivation repeated. The passivation and rinse solutions should be replaced every fourth use, or discarded weekly.

4.2.4 Prepare recycled sample containers by detergent washing (using a stiff nylon brush where necessary), followed by rinsing with Type II water, methanol and methylene chloride. As each part is treated with the final solvent, dry with filtered air or dry nitrogen and inspect for any contaminating residue. Discard any container exhibiting visual contamination. Cover all open surfaces with aluminum foil or Teflon film, using elastic bands to secure.

4.2.5 Assembly and leak-checking of the entire train in the laboratory is highly recommended to reveal the need for replacement of gaskets or defective components. The leak-check procedure is described in Paragraph 4.4.3.11. Substitution of Viton-A gaskets for Teflon may facilitate meeting the allowable leak rate. A length of Teflon tape stretched around the circumference of each flanged connection underneath the ring clamp also greatly reduces inward air leakage.

4.3 Preliminary field determinations:

4.3.1 Select the sampling site and remove any accumulated scale and corrosion from the sampling portholes. Determine the stack static pressure, temperature, and velocity profile using EPA Method 2 (see References); a leak-check of the pitot lines prior to conducting these measurements is highly recommended. Approximate the moisture content using EPA Method 4 (Approximation Method) or alternate means such as drying tubes, wet bulb/dry bulb or condensation techniques, stoichiometric calculations, or previous experience. Determine the dry molecular weight of the stack gas by performing an ORSAT or GC/TCD analysis for CO, CO_2, O_2 and N_2 on an average of three grab samples taken from either the center of the duct or a point no closer to the stack walls than **1.0 m (3.3 ft).**

4.3.2 Select a nozzle size based upon the calculations below, ensuring that it will not be necessary to change the nozzle during the sampling run to maintain near-isokinetic sampling rates.

4.3.2.1 To calculate the required nozzle diameter, first calculate the Average Stack Gas Velocity:

$$(V_s)_{avg} = K_p C_p (\sqrt{(\Delta P)})_{avg} \left[\sqrt{\frac{(T_s)_{avg}}{P_s M_s}} \right]$$

where:

$(V_s)_{avg}$ = Average stack gas velocity, ft/sec;

$$K_p = 85.48 \left[\frac{\text{ft}}{\text{sec}} \left[\frac{(\text{lb/lb-mole})(\text{in. Hg})}{^\circ\text{R}(\text{in. } H_2O)} \right]^{1/2} \right];$$

C_p = Pitot tube coefficient, dimensionless;

ΔP = Velocity head of stack gas, in. H_2O;

$(T_s)_{avg}$ = Average stack gas temperature, °R;

P_s = Absolute stack gas pressure, in. Hg; and

M_s = Molecular weight of stack gas (wet basis), lb/lb-mole.

4.3.2.2 Then calculate the required Nozzle Diameter (D_n):

$$D_n = 0.831 \left[\frac{(T_s)_{avg}}{(V_s)_{avg} P_s} \right]$$

4.3.3 Select a suitable probe length such that one or more points of average velocity can be sampled. Determine the total length of sampling time by comparing the anticipated average sampling rate to the volume requirement of 30 dscm (approximately 1,060 dscf).

4.3.3.1 The anticipated Average Sampling Rate is calculated as follows:

$$Q_{mo} = (1-B_{ws})Q_{st} \frac{P_{st} (T_m)_{avg}}{P_m (T_{st})}$$

where:

Q_{mo} = Flow rate through orifice at meter conditions, ft^3/min (dry);

B_{ws} = Volume fraction of water vapor in the gas stream, dimensionless;

Q_{st} = Design sampling flowrate for SASS train, 4.0 scfm;

P_{st} = Standard presssure, 29.92 in. Hg;

$(T_m)_{avg}$ = Average gas temperature (estimated) at the dry gas meter, °R;

P_m = Absolute meter pressure, in. Hg, calculated by

$$P_m = P_b + \frac{(\Delta H)_{est.avg.}}{13.6}$$

where:

$(\Delta H)_{est.avg.}$ = Estimated average ΔH across orifice, 3-4 in. H_2O, and

P_b = Barometric pressure (corrected), in. Hg; and

T_{st} = Standard temperature, 528°R.

None of these definitions has an English/metric equivalent.

4.3.3.2 Using this result, obtain the approximate sampling time by dividing the required sample volume by the estimated sampling flowrate.

4.3.4 Finally, calculate the Orifice Pressure Drop needed to maintain near-isokinetic sampling conditions from the equation:

$$\Delta H_i = \frac{P_m}{(T_m)_{avg}} \left[\frac{0.1924\ Q_{mo}}{J_i D_{oi}^2}\right]^2$$

where:

ΔH_i = Required ΔH across the orifice, in. H_2O;

P_m = Absolute meter pressure, in. Hg (calculated the same way as for Average Sampling Rate above);

$(T_m)_{avg}$ = Estimated average gas temperature at the dry gas meter, °R;

J_i = Orifice coefficient for orifice "i" (see Blake, 1977, and Section 7.0 of this method for determining orifice coefficients); and

D_{oi} = Orifice diameter, in. (information supplied upon purchase of the SASS train; the largest diameter orifice is typically best suited for the SASS sampling rate of 4.0 scfm).

4.3.5 It is desirable, but not required, to sample more than one point of average velocity during a SASS run. Allocate equal intervals of the total sampling time estimated above to each sampling point chosen if more than one point will be sampled.

4.4 Preparation of collection train:

4.4.1 An integral part of preparing the collection train is securing sufficient electrical power to operate for an extended period of time without interruption. Three separate circuits -- two 30-amp and one 20-amp -- are required. It is highly recommended that one sampling pump and one control box power cord (probe heater) be placed on one of the 30-amp circuits, and the other sampling pump and control box power cord (oven heater and temperature readout) be placed on the other 30-amp circuit. The organic module coolant pump and temperature controller should be placed on the smaller 20-amp circuit.

4.4.2 During assembly of the train, keep the inner surfaces of each component covered until it is integrated into the system and sampling is about to begin. Fill the sorbent trap section of the organic module with approximately 150 g of clean adsorbent XAD-2 resin. To avoid contamination, the trap should be placed upon a clean surface (i.e., aluminum foil rinsed with methylene chloride and air-dried) while filling; gloves should be worn. Pack the trap uniformly to eliminate potential channeling. Place 500 mL of Type II water or other appropriate solution into the first and second impingers, leave the third impinger empty, and place a preweighed portion of silica gel into the fourth.

NOTE: The choice of impinger solutions depends upon whether these will be used to collect selected inorganic species or simply to condense water vapor from the gas stream to measure percent moisture. For example, in an incinerator combusting chlorinated organic material, a solution of dilute base would typically be used to collect hydrochloride acid emissions.

Using blunt-tipped tweezers, place a tared filter into the filter holder. Ensure that the filter is centered and the gasket properly placed to prevent the gas stream from circumventing the filter. On the probe, mark the locations of the chosen sampling points with heat-resistant tape or paint.

4.4.3 The stepwise procedure for assembly of the train follows:

4.4.3.1 Place the oven on a table or rollers that will be used as a support throughout the run.

4.4.3.2 Assemble the three cyclones, using the vortex breaker supplied with the cyclone in the 10-um cyclone only. (To minimize leaks throughout the system, a strip of Teflon tape should be stretched around the circumference of each flanged seal and the ring clamp placed over and secured.) Do not use the vortex breakers supplied with the 3- and 1-um cyclones in the 3- and 1-um cyclones. Actual calibration data has shown that the use of the vortex breakers in the two smaller cyclones may result in unreproducible particle-size cutoff diameters (the particle size at which 50% collection efficiency is exhibited).

4.4.3.3 Attach the filter holder to the outlet of the 1-um cyclone and place the cyclones and filter holder together in the oven. Preheat a spare filter holder containing a tared filter on the oven floor; cover the holder openings with aluminum foil.

4.4.3.4 Attach the probe to the oven and to the 10-um cyclone.

4.4.3.5 Place the impingers in the tray in the impinger case and make the apropriate interconnections.

4.4.3.6 Connect the organic module inlet to the filter housing outlet and the organic module outlet to the first impinger inlet.

4.4.3.7 Connect the vacuum pumps in parallel to the fourth impinger outlet.

4.4.3.8 Connect all temperature sensors and power lines to the control unit. Check temperature indicators and controllers at ambient temperature.

4.4.3.9 Activate gas cooling system. Begin monitoring the XAD-2 temperature. Always check coolant level before supplying power. Ensure proper gas cooling system temperature before proceeding.

NOTE: IT IS EXTREMELY IMPORTANT THAT THE XAD-2 RESIN TEMPERATURE NEVER EXCEED 50°C, AS DECOMPOSITION WILL OCCUR. DURING TESTING, THE XAD-2 TEMPERATURE MUST NOT EXCEED 20°C FOR EFFICIENT CAPTURE OF THE SEMIVOLATILE ORGANIC SPECIES OF INTEREST.

4.4.3.10 Heat oven and probe to 204°C (400°F).

4.4.3.11 Run gas flow leak-check. The following instructions will facilitate the leak-checking procedure:

a. Open the isolation ball valve and plug the inlet to the probe with a rubber stopper or appropriate airtight cap.

b. Start the pumping system with the bypass valves fully open and the coarse valves completely closed. Partially open the coarse valves and slowly close the bypass valves until a vacuum of 127 mm Hg (5 in. Hg) is reached. Do not reverse the direction of the bypass valves as backflushing of the impinger solutions into the organic module will result. If the desired vacuum is exceeded, either leak-check at the higher vacuum or terminate the leak-check and begin again. Allow the system to equilibrate and measure the leakage rate. The allowable leak rate for the SASS train is 0.0014 m^3/min (0.05 ft^3/min) at this vacuum. Close the isolation ball valve and evacuate the train to 281 mm Hg (15 in. Hg). The leak rate through the back half of the train should be less than 0.0014 m^3/min (0.05 ft^3/min) at this vacuum.

c. When the leak-check is complete, slowly remove the plug from the probe tip and then slowly open the isolation ball valve.

d. When the vacuum drops to 127 mm Hg (5 in. Hg) or less, immediately close both coarse control valves together. Switch off the pumping system and reopen the bypass valves. The bypass valves should not be opened until the coarse valves have been closed.

4.4.4 Only post-test leak-checks are mandatory; however, experience has shown that pre-test leak-checks and leak-checks following component changes are necessary to ensure that invaluable sampling time is not lost as a result of an oversight or defective component.

4.5 Sample Collection: Constant monitoring of train operations before, during, and after the particulate run is essential in maintaining sample integrity. Listed below are sample collection guidelines:

4.5.1 With the coarse valves closed and bypass valves open, turn on the vacuum pumps and allow them to warm up. As the probe and oven are heating, prepare a SASS run data sheet as shown in 40 CFR Appendix A (see References below). Barometric pressure data should be recorded at least at the beginning and end of the run; once per hour is preferred.

4.5.2 When operating temperatures have been reached, place the probe in the stack at the first designated sampling point, turn on the vacuum pumps, adjust the sampling flowrate to achieve the calculated ΔHi, and start the elapsed timer. If, however, the gas stream is under medium or high negative pressure, it becomes extremely important to start the vacuum pumps just before placing the probe in the gas stream, and to continue to operate the pumps until just after the probe has been removed from the gas stream. This will eliminate the possibility of lifting of the filter or backflushing of the filter and cyclone particulate catches at any time.

4.5.3 Seal the sampling port around the probe to prevent introduction of dilution air at this point. Record the clock time of the start of the test.

4.5.4 Using the criteria outlined above under Paragraph 4.3, Preliminary Field Determination, place the integrated fixed gas bag or bulb sampling probe into the gas stream and begin sampling. Collect three samples during the SASS run; record the initial and final clock times of each integrated fixed gas sample.

4.5.5 Monitor and maintain all temperatures and the calculated ΔH and record the data at equal intervals of 10-15 min.

4.5.6 Add crushed ice to the impinger section and drain excess water as necessary.

4.5.7 Without interrupting sampling, drain the condensate initially every 30-45 min, and afterward as necessary. Ensure that the vessel into which the reservoir is drained forms an airtight system with the reservoir using a connecting Teflon line, and is placed well below the level of the reservoir itself. To drain the reservoir, close the solation ball valve and open the drain valve. Allow the system to evacuate for 10-20 sec. Carefully open the isolation valve. The condensate should siphon from the reservoir into the storage vessel. Close the drain valve when the siphoning action of the condensate ceases.

4.5.8 Replace the filter when it becomes impossible to maintain near-isokinetic sampling rates but not more frequently than every 20 to 30 min. Always terminate and initiate sampling by adjustment of the coarse pump valves and then the bypass valves. A spare filter holder and filter, if available, should be preheating in the oven at all times. Conduct leak-checks before and after changing the filter. Recall previous instructions concerning removal and reintroduction of the probe into the duct.

4.5.9 At the same time, check the 1-um cyclone reservoir for remaining capacity, taking care not to contaminate the contents during this inspection.

4.5.10 When replacing a filter, start and stop the fixed gas sampling concurrently with the SASS sampling; record the clock time and dry-gas-meter reading whenever sampling is interrupted.

4.5.11 Upon collection of the required 30 dscm (1,060 dscf), remove the probe from the gas stream and shut down the pumps as previously instructed. Record the final dry-gas-meter reading and clock time; turn off all heaters. Conduct the post-test leak-check when the probe tip can be safely handled. Do not cap the probe while initially cooling, because this will create a vacuum inside that will cause disruption of the cyclone and filter particulate catches when it is released. Instead, use aluminum foil to cover probe openings. Before the probe is transported, secure the aluminum foil covers with elastic bands. Leak-check the pitot lines per EPA Method 2 to validate velocity heat data.

5.0 SAMPLE RECOVERY

The sample handling and transfer procedures outlined in this section have been adopted from the Level 1 procedures. The flow diagrammatic representation of the sample recovery procedures shown in Figures 3, 4, and 5 can be found in the Level 1 Sampling and Analysis Procedures Manual.

5.1 Disassembly of the SASS Train: At the conclusion of the sampling run, the train is disassembled and transported to the prepared work area as follows:

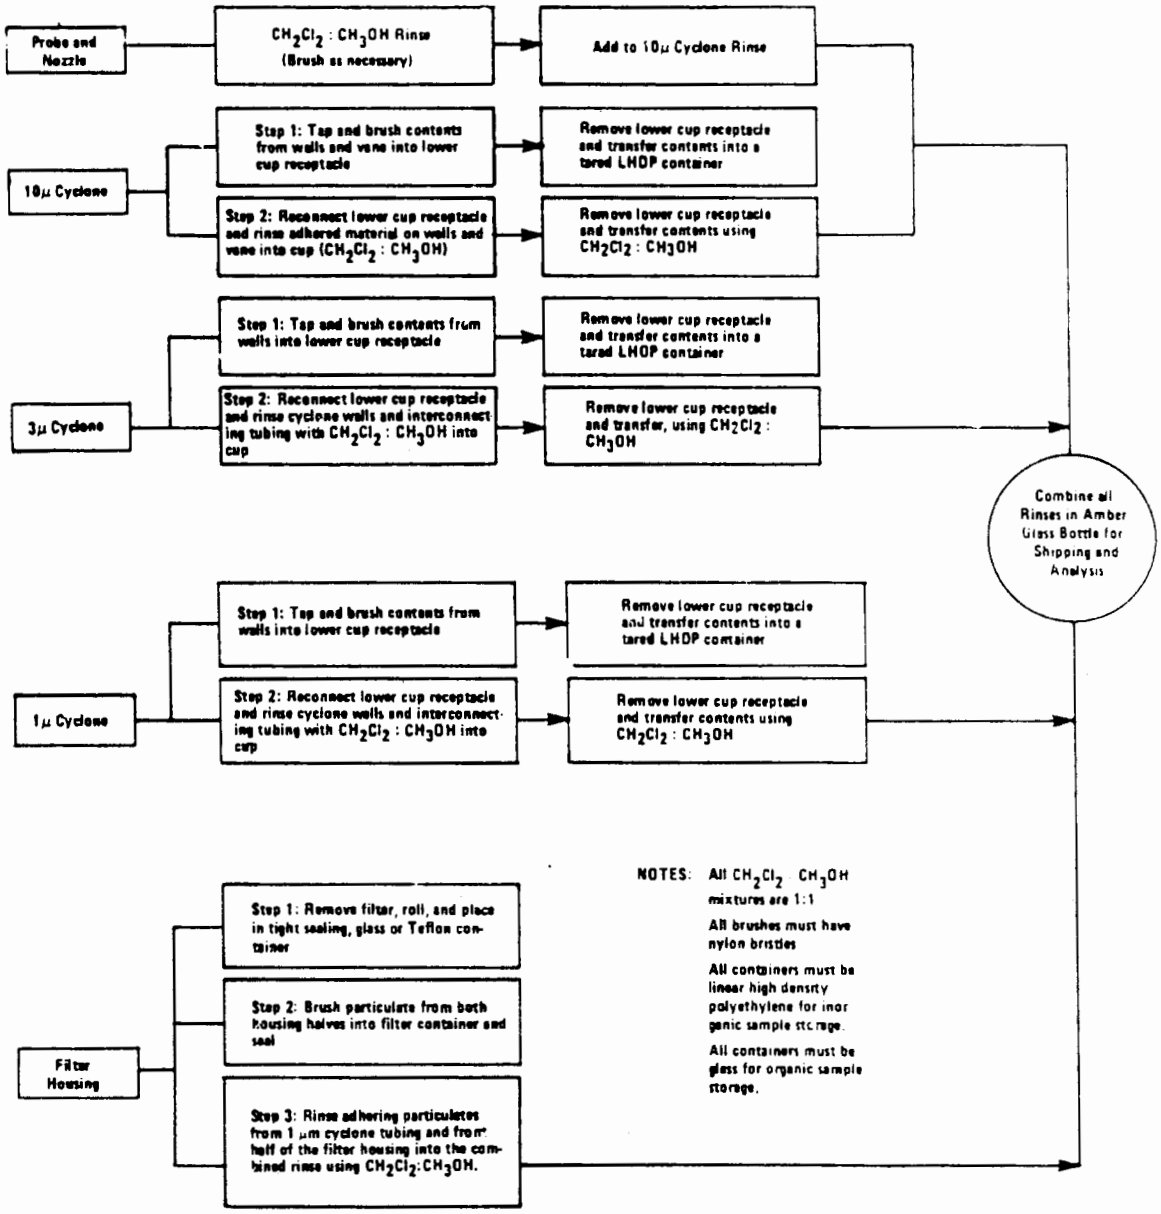


Figure 3. Sample Handling and Transfer Nozzle, Probe, Cyclones and Filter.

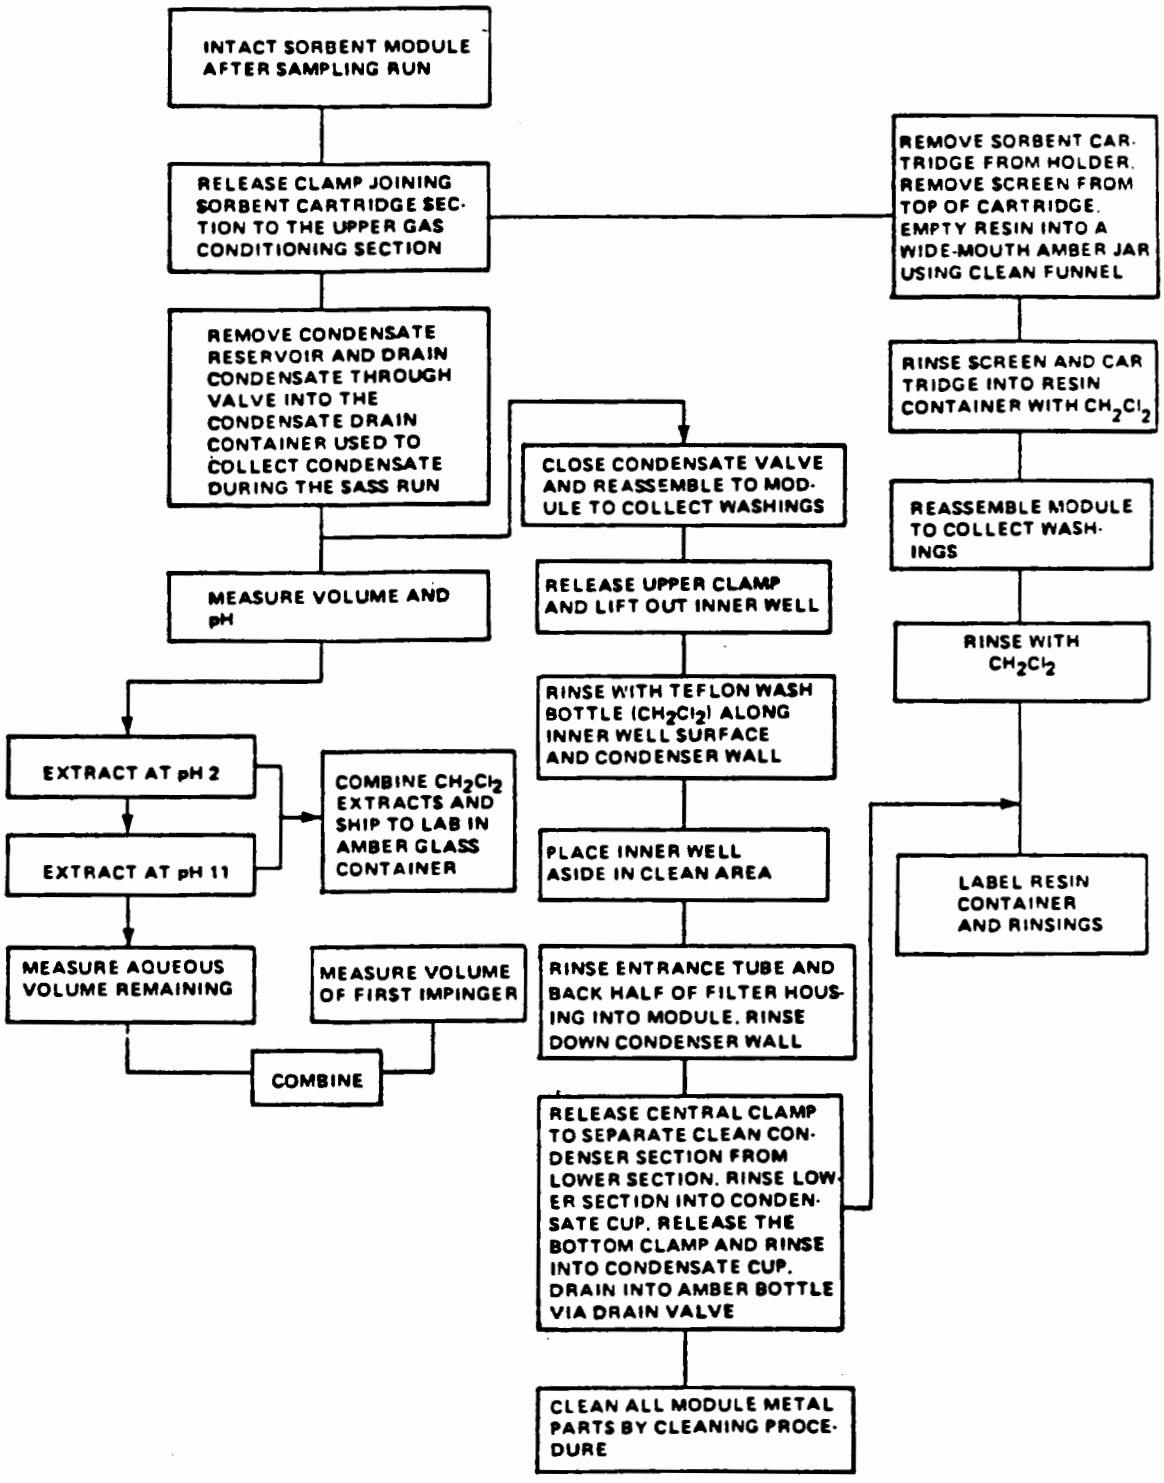

Figure 4. Sample Handling and Transfer XAD-2 Module.

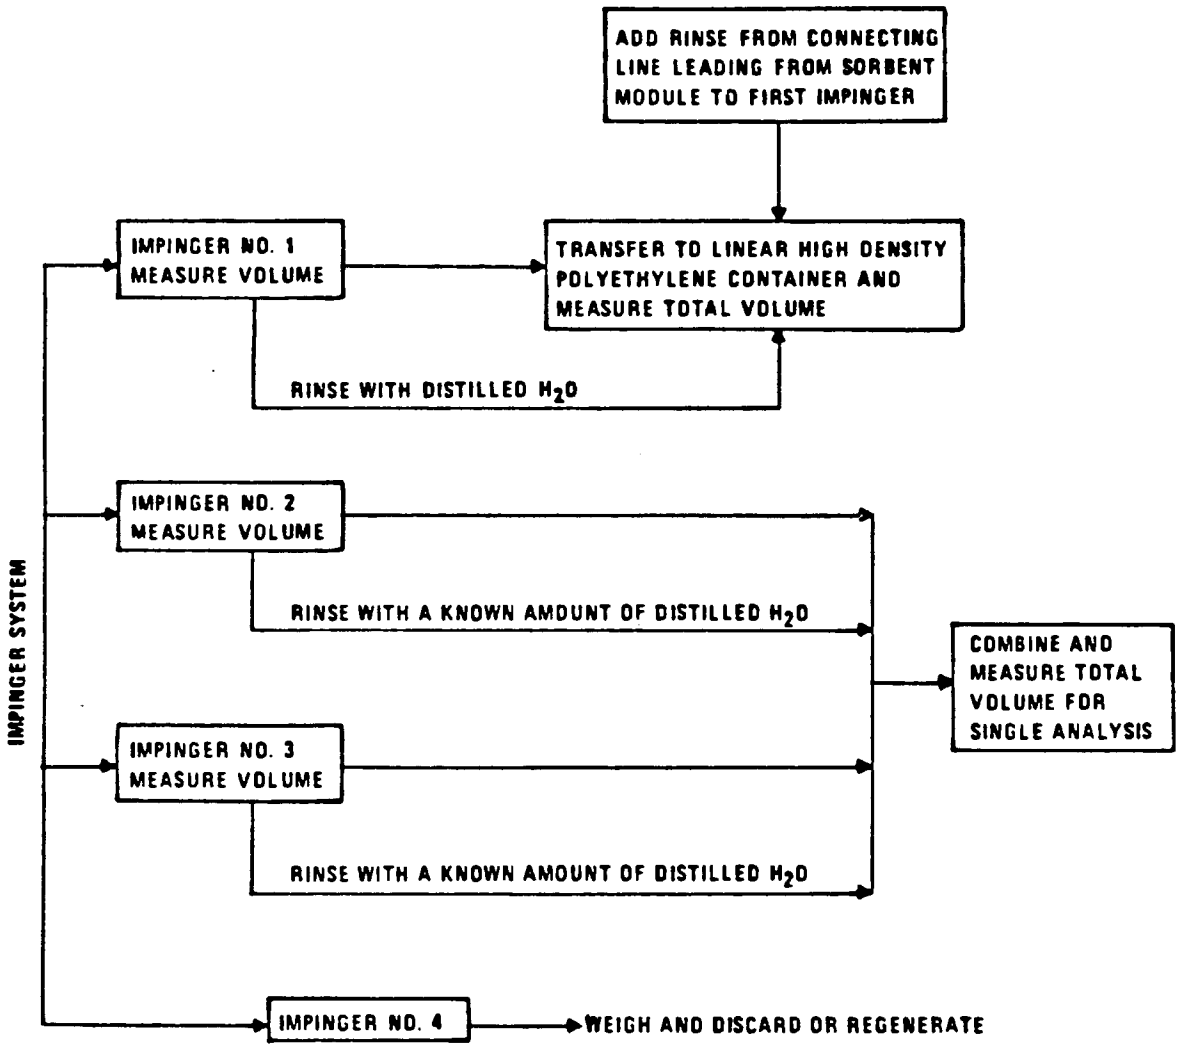

Figure 5. Sample Handling and Transfer Impingers.

5.1.1 Leaving the fan operating, open the cyclone oven door to expedite cooling. When the probe can be safety handled, disconnect from the 10-um cyclone inlet. Wipe off external particulate matter near the probe tip and place a cap over each end. The probe must remain level throughout this procedure.

NOTE: CARE MUST BE TAKEN TO AVOID TIGHTLY CAPPING TRAIN COMPONENTS AS THEY ARE COOLING FROM STACK OR OVEN TEMPERATURES. THIS WILL ELIMINATE THE POSSIBILITY OF CREATING A VACUUM INSIDE WHICH, WHEN RELEASED, MAY DISRUPT AND BACKFLUSH THE CYCLONE AND FILTER PARTICULATE CATCHES INTO ONE ANOTHER.

5.1.2 Disconnect the line joining the filter outlet to the XAD-2 module and cap off:

a. The 10-um cyclone inlet;

b. The filter holder outlet; and

c. The inlet of the line just disconnected from the filter holder outlet.

5.1.3 Disconnect the filter holder and cap the inlet. Set aside with the inlet facing upward. Cap the outlet of the 1-um cyclone. The cyclones must remain upright throughout this procedure. The cyclones can now be disconnected from one another or moved to the recovery area as a single unit.

5.1.4 Disconnect the line joining the XAD-2 module to the impinger system at the organic module outlet. Cap the organic module outlet.

5.1.5 Disconnect the silica gel impinger outlet from the vacuum line to the pumps; cap off the first impinger inlet and the fourth impinger outlet.

5.2 Nozzle, Probe, Cyclones, and Filter: The step-by-step procedures for the recovery of particulate material collected in the nozzle, probe, and cyclones, and on the filter are detailed below:

5.2.1 Carefully transfer the filter from the filter housing to its original glass Petri dish; a pair of clean blunt-tipped tweezers and a flat spatula should be used for handling the filter. Using a clean nylon-bristled brush, add any particulate material from the front half of the filter housing to the Petri dish; seal the Petri dish around the circumference with 1-in.-wide Teflon tape; store with the collected particulate material facing upward.

5.2.2 Tap and brush any particulate material adhering to the walls of the upper chamber of the 1-um cyclone into the lower cup; remove the cup and quantitatively transfer the bulk contents to a wide-mouth amber glass jar. Rinse the brush with methanol/methylene chloride (1:1 v/v) into the probe rinse container.

5.2.3 Recover the contents of the 3-um cyclone in the same manner, using a separate wide-mouth amber glass jar.

5.2.4 Recover the contents of the 10-um cyclone in the same manner, using a separate wide-mouth amber glass jar.

5.2.5 Reconnect the lower cups of each cyclone and rinse any particulate material adhering to the walls down into the cups with the methanol/methylene chloride mixture until the walls appear clean. Remove the lower cups and transfer the contents to the probe rinse container. Rinse the interconnecting tubing among the cyclones into the probe rinse in the same manner.

5.2.6 Carefully remove the probe nozzle and clean the inside surface by rinsing with the methanol/methylene chloride (1:1 v/v) from a wash bottle and brushing with a nylon-bristle brush. Brush until the rinse shows no visible particles; make a final rinse of the inside surface.

5.2.7 Rinse the probe liner (preferably with two people so as to minimize the possibility of accidental sample loss) with methanol/ methylene chloride (1:1 v/v) by tilting and rotating while spraying solvent into the upper end and allowing the lower end to drain into the sample container. Follow rinsing with brushing and rinsing from the upper to the lower end. Push the brush through the liner with a twisting action; ensure that the sample container is placed under the lower end. Brush until the rinse appears clean; perform a final rinse. Inspect the inner surface of the liner for cleanliness. Rinse any particulate material remaining on the brush into the sample container.

5.2.8 Clearly label all containers according to the coding scheme given in Table 1; cover each label completely with transparent tape; mark liquid levels and store all liquid samples on ice.

5.3 XAD-2, condensate, and organic module: Sample recovery of the entire organic module may be conducted independently from the previous steps. The step-by-step procedure for recovery of this stage is given below:

5.3.1 Rinse a 1-ft x 1-ft square of aluminum foil (dull side) with methylene chloride and allow to air dry.

5.3.2 Release the clamp joining the XAD-2 cartridge section to the upper gas conditioning system (second clamp); remove the XAD-2 cartridge from the holder and place upon the clean aluminum foil. GENTLY pry loose or unscrew (depending upon the design) the ring securing the fine mesh screen on the top of the cartridge. Remove the screen and quantitatively transfer the XAD-2 to a clean glass amber jar. A large, clean glass funnel should be used for the transfer. Rinse the inner surfaces of the cartridge and the funnel with methylene chloride as necessary to remove adhering XAD-2. Any XAD-2 that escapes onto the aluminum foil should be retrieved and added to the sample.

TABLE 1. SUGGESTED FORMAT FOR SAMPLE CODING AND IDENTIFICATION

Sample Code	Container	Size	Sample description
1C	Amber glass	100 mL, wide-mouth	1-m cyclone catch
3C	Amber glass	100 mL, wide-mouth	3-m cyclone catch
10C	Amber glass	100 mL, wide-mouth	10-m cyclone catch
PF-a,b,c,...	Glass Petri dish	>6-in. diam.	Particulate filter(s)
PR	Amber glass	1 liter	Methylene chloride/ methanol front-half rinse
PRB	Amber glass	500 mL	Methylene chloride/ methanol blank
MRX	Amber glass	1 liter	Methylene chloride back half rinse
MRXB	Amber glass	500 mL	XAD-2 resin blank
CD-LE	Amber glass	1 liter	Methylene chloride condensate extract
CD-LEB	Amber glass	500 mL	Methylene chloride blank
AR-I1	HDLP[a]	1 liter	Aqueous residue of condensate combined with first impinger catch
I1B	HDLP	500 mL	First impinger blank (distilled H_2O or other appropriate solution)
I23	HDLP	1 liter	Second and third impinger catches
I23B	HDLP	500 mL	Second and third impinger blank (distilled H_2O or other appropriate solution)

[a]HDLP = High Density Linear Polyethylene.

5.3.3 Replace the screen on the cartridge, reinsert the cartridge into the module, and reassemble the module. One person can accomplish this task by butting the lower section in its proper sealing position up against the upper section while securing the ring clamp. One or more wooden spacers approximately 1/2 in. thick are suggested for this purpose.

5.3.4 Open the condensate reservoir valve and drain the remaining condensate into the condensate storage container. Measure and record the volume and pH (using narrow-range pH paper) of the entire condensate.

5.3.5 Transfer the entire condensate to an appropriately-sized separatory funnel. Adjust the pH of the condensate (as indicated by the narrow-range pH paper) to 1-2 using ultrapure or reagent grade nitric acid. Extract the condensate three times with methylene chloride, each time with fresh portions measuring 8-10% of the total condensate volume. If the volume of the condensate is extremely large (>1800 mL), the condensate may be extracted in portions, but fresh volumes of methylene chloride must be used for each and every extraction. After each addition of methylene chloride to the separatory funnel, the funnel must be shaken with periodic venting through the stopcock to relieve any vapor pressure. For safety, the tip of the separatory funnel should <u>always</u> be directed away from the face and eyes while venting. When no further vapor pressure can be vented after shaking, the funnel should be mounted upright on a ring stand, the cap removed, the layers allowed to separate, and the methylene chloride (bottom) layer removed. If an emulsion forms equal to more than one-third the size of the solvent layer, reagent-grade sodium chloride should be added until the emulsion is broken or reduced to meet the above criterion. The emulsion interface should <u>not</u> be included as part of the methylene chloride extract.

5.3.6 Following the third extraction of the acidified condensate, adjust the pH of the aqueous residue to 11-12 with a 50% w/w solution of sodium hydroxide (as indicated by narrow-range pH paper), extract with methylene chloride in the same manner, and combine the methylene chloride extracts of the condensate at the high and low pH readings.

5.3.7 Transfer the aqueous residue from this extraction to a clean Nalgene container; retain for later addition of the first impinger solution.

5.3.8 Ensure that the condensate reservoir valve is closed, release the upper clamp, and lift the inner well halfway out of the module. Rinse the inner well into the XAD-2 module using a Teflon wash bottle containing methylene chloride, so that the rinse travels down the module and into the condensate collector. Then remove the well entirely and place to one side on a clean surface (aluminum foil prerinsed with methylene chloride). Rinse the entrance tube into the module interior; rinse the condenser wall allowing solvent to flow down through the system and collect in the condensate cup.

5.3.9 Release the central clamp again and separate the lower section (XAD-2 cartridge holder and condensate cup) from the upper.

5.3.10 Lift the empty XAD-2 cartridge halfway out of the mid-section and rinse the outer surface down into the condensate cup. Remove the cartridge completely to a clean surface (aluminum foil rinsed with methylene chloride).

5.3.11 Rinse the empty XAD-2 section into the condensate cup. Open the condensate reservoir valve and drain into the XAD-2 sample storage container (wide-mouth amber glass jar).

5.3.12 Rinse the condensate reservoir and combine the rinse with the XAD-2 resin as above.

5.3.13 Clearly label all containers according to the coding scheme presented in Table 1; cover each label completely with transparent tape; mark liquid levels and store all liquid samples on ice.

5.4 Impingers: Sample recovery from the impingers may also be accomplished independently of the other two sections of the SASS train. The procedures are described below.

5.4.1 **First impinger:**

5.4.1.1 Measure the volume of liquid in the impinger with a graduated cylinder; combine with the aqueous residue from the condensate.

5.4.1.2 Rinse the line connecting the XAD-2 module to the first impinger with Type II water; transfer the rinse to the same graduated cylinder. Rinse the impinger twice more with Type II water, combining all rinses in the graduated cylinder. Measure the total rinse volume and add to the sample. Rinse the graduated cylinder with a known amount of Type II water and add to the sample. Record all volumes on the sample recovery sheet.

5.4.2 **Second and third impingers:**

5.4.2.1 Measure and record the combined volume of liquid in the impingers in a large (1,000-mL) graduated cylinder; transfer to a clean sample storage container.

5.4.2.2 Rinse the line connecting the first and second impinger into the second impinger and the line connecting the second and third impinger into the third impinger. Transfer the rinses to the same graduated cylinder. Rinse each impinger twice again with Type II water, combining all rinses in the graduated cylinder. Measure and record the combined rinse volume and add to the sample. Rinse the graduated cylinder with a known amount of Type II water and add to the sample. Record this additional rinse volume and add to the impinger rinse volume above.

5.4.2.3 Clearly label all sample containers according to the coding scheme presented in Table 1; cover each label completely with transparent tape; mark fluid levels and store all liquid samples on ice.

5.4.3 **Fourth impinger:**

5.4.3.1 Transfer the silica gel to its original container. Weigh to the nearest 0.1 g on a triple-beam balance, and record the weight.

5.4.3.2 Discard or regenerate.

6.0 SAMPLE PREPARATION FOR SHIPMENT

6.1 Prior to shipment, recheck all sample containers to ensure that the caps are securely tightened. Seal the lids of all Nalgene containers around the circumference with vinyl tape and those of glass containers with Teflon tape. Ship all liquid samples on ice and all particulate filters with the particulate catch facing upward. Ship peroxide solutions (impinged) in a separate container.

7.0 CALIBRATION

7.1 All calibration results should be recorded on appropriate data sheets and fastened securely into a separate section in the field sampling notebook. Samples of blank data appear in 40 CFR 60 (1979), Appendix A.

7.2 Probe nozzles:

7.2.1 Probe nozzles must be calibrated before each initial use in the field. Using Vernier calipers or micrometers, measure the inside diameter of the nozzle to the nearest 0.025 mm (0.001 in.). Perform ten separate measurements using different diameters; obtain the average of the ten measurements. The difference between the highest and lowest measurement results must not exceed 0.1 mm (0.004 in.). When nozzles become nicked, dented, or corroded, they must be reshaped, sharpened, and recalibrated before reuse. Recalibration of the nozzle before each run in gas streams that are highly corrosive is strongly recommended, as the nozzle diameter may be changing slightly from one run to the next. Each nozzle must be permanently and uniquely engraved.

7.3 Pitot tube

7.3.1 If the Type-S pitot tube conforms to the construction specifications (the face openings are not visibly nicked, dented, or corroded) and the pitot tube/probe assembly meets the intercomponent spacings outlined in EPA Method 2 (see References), the pitot tube need not be calibrated to meet federal and many state testing requirements; a correction coefficient may be assigned in these cases. Some states, however, require that, once used, pitot tubes must be calibrated in a

wind tunnel. Specific state requirements such as this must be unequivocally stated prior to testing. In either case, pitot tube face openings should be inspected before each run to ensure that there has been no change in appearance since their construction or most recent calibration.

7.4 Metering system:

7.4.1 Before each initial use in the field, the metering system shall be calibrated using a standard bell prover of the proper size. (A standard bell prover is recommended for this procedure because the displacement volume of commercially available wet test meters is typically insufficient.) A meter stick should be used to indicate the distance travelled by the inner tank during the measurement. Figure 6 illustrates a suitable arrangement for the calibration. It is highly recommended that the dry gas meter be adjusted until the ratio of the dry gas meter volume to the standard bell prover volume equals 1.00 $\pm$ 0.01, to ensure that the calculated ΔH_i will result in near-isokinetic sampling rates. The calibration procedure follows:

7.4.1.1 Perform both a positive (pressure) and a negative (vacuum) leak-check of the metering system. For the negative leak-check, include only the orifice Magnehelics (reg. trademark), dry gas meter, and two vacuum pumps by removing the vacuum line connecting the fourth impinger to the vacuum pumps at the common side of the pump inlet tee, and replacing the line with a plain-end male quick connect. Tightly cap this end and leak-check in the manner outlined above under 4.4.3.11. For the positive leak-check, connect a short length of rubber tubing to the "gas exhaust" port on the SASS control module. Disconnect and vent the low side of the orifice magnehelic; close off the low-side orifice tap. Pressurize the system to 13-18 cm H_2O (5-7 in. H_2O) by blowing into the rubber tubing; pinch off the tubing and observe the magnehelic for one minute. The magnehelic reading must remain unchanged during that time period. Any loss of magnehelic pressure indicates a leak that must be corrected.

7.4.1.2 Upon obtaining satisfactory leak-checks, connect the metering system to the standard bell prover.

7.4.1.3 Using the control box Magnehelic (reg. trademark) indicator, set the pumping rate corresponding to a ΔH of 1 in. Hg. Turn the pumps off using the switches.

7.4.1.4 Record the initial temperature and pressure of the bell prover and the initial temperature and reading of the dry gas meter. Record the barometric pressure every hour.

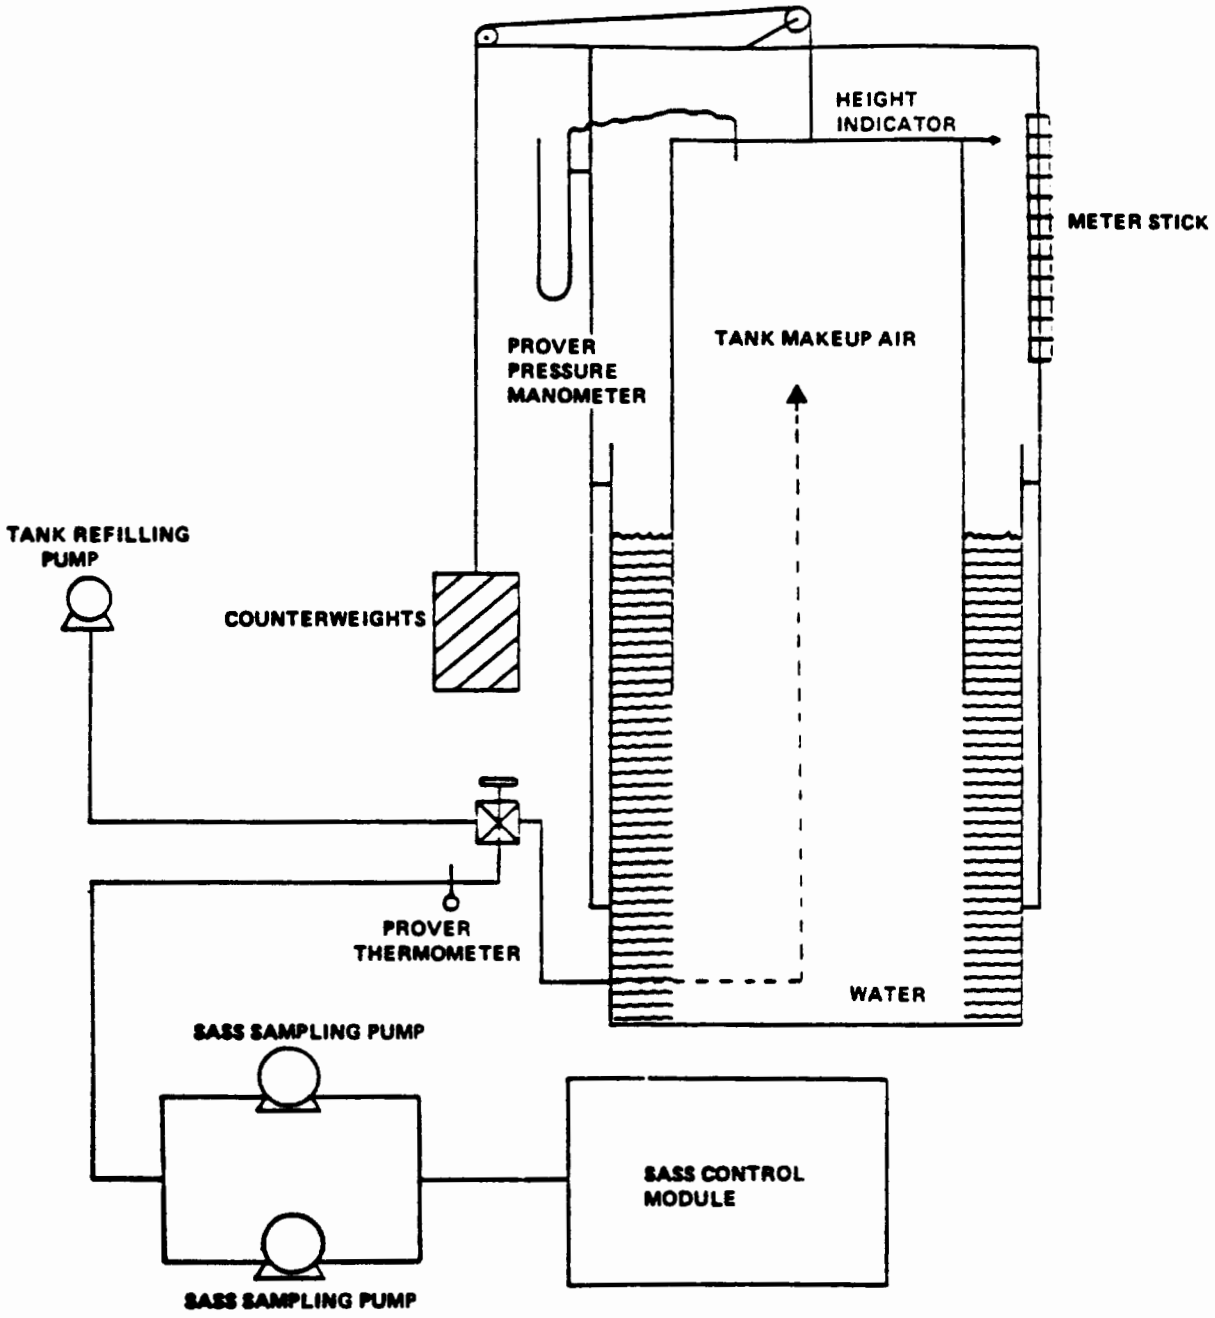

Figure 6. Schematic Diagram of Standard Bell Prover Arrangement for SASS Dry-Gas-Meter Calibration.

7.4.1.5 Disconnect the metering system and pump the inner tank of the bell prover to a convenient height. Reconnect the metering system and record the height.

7.4.1.6 Start the pumps and a stopwatch simultaneously; evacuate the tank for 3 min.

7.4.1.7 After 3 min, turn off the pumps using the switches. Record the final inner tank height, the final dry gas meter reading and temperature, and the bell prover final temperature and pressure.

7.4.1.8 Repeat steps 3-7 using ΔH settings of 2, 4, and 6 in. H_2O.

7.4.1.9 Duplicate the entire procedure as a check; repeat the entire procedure after each adjustment of the dry gas meter.

7.4.1.10 Calculate the Dry-Gas-Meter Correction Coefficient, the ratio of the volume of gas measured by the dry gas meter to the standard bell prover, both corrected to standard conditions and on a dry basis. The ratio reduces to:

$$\gamma = \frac{V_{pvr(std)}}{V_{dgm(std)}} = \frac{V_{pvr} P_{pvr} T_{dgm}}{V_{dgm} P_{dgm} T_{pvr}}$$

where:

γ = Dry gas meter correction coefficient, dimensionless;

$V_{dgm(std)}$ = Volume of gas measured by the dry gas meter on a dry basis, corrected to standard conditions, dscm (dscf);

$V_{pvr(std)}$ = Volume of gas measured by the standard bell prover on a dry basis, corrected to standard conditions, dscm (dscf);

V_{dgm} = Volume of gas measured at dry-gas-meter conditions, $m^3(ft^3)$;

= Final volume reading - initial volume reading;

V_{prv} = Volume of gas measured at standard bell prover conditions, $m^3(ft^3)$

= K_{pvr} x (difference in meter stick height readings),

where:

K_{pvr} = number of ft^3 of air displaced represented by each cm of movement along the meter stick, $m^3/cm(ft^3/cm)$;

P_{dgm} = Absolute meter pressure, mm Hg (in. Hg)

= Barometric pressure + $\Delta H/13.6$;

P_{pvr} = Absolute prover pressure, mm Hg (in. Hg)

= Barometric pressure - [(ΔP) prover manometer]/13.6;

T_{pvr} = Absolute bell prover temperature, °K (°R); and

T_{dgm} = Absolute dry-gas-meter temperature, °K (°R).

7.4.1.11 Calculate the Orifice Constants using the following equations:

a. $$Q_{mo} = (1-B_{ws})\, Q_{std}\, \frac{P_{std} T_{m(avg)}}{P_m T_{std}}$$

where:

Q_{mo} = Sampling flowrate at orifice, ft^3/min (dry);

B_{ws} = Proportion by volume of water in ambient air, dimensionless;

Q_{std} = Standard sampling flowrate for SASS, 4.0 scfm (wet);

P_{std} = Standard absolute pressure, 29.92 in. Hg;

$T_{m(avg)}$ = Average meter temperature, °R;

P_m = Absolute meter pressure (barometric pressure + $\Delta H/13.6$), in. Hg; and

T_{std} = Standard temperature, 528°R.

b. $$J_i = \frac{Q_{mo}}{A_{oi}} \left[\frac{T_{m(avg)}}{P_m M_m} R \Delta H_i 2 g_c \right]^{-1/2}$$

where:

J_i = Orifice coefficient for orifice "i";

Q_{mo} = Sampling flowrate at orifice, ft^3/min (dry);

A_{oi} = Orifice area [π(diameter)^2]/4, in.^{2};

$T_{m(avg)}$ = Average meter temperature, °R;

P_m = Absolute meter pressure (see equation above), in. Hg;

M_m = Molecular weight of air, 29.0 lb_m/lb-mole;

R = Gas law constant, 1545 ft-lb_f/°R lb-mole;

ΔH_i = Orifice "i" pressure drop, in. H_2O; and

g_c = Gravitational constant, 32.17 lb_m-ft/lb_f sec^2.

7.4.1.12 The orifice constants may be determined without the bell prover by noting the dry-gas-meter volumes obtained by pumping at 1, 2, 3, and 6 in. H_2O for 3-min periods. The obtaining of consistent values when checking orifice constants in the field may be used as a rough indication of a valid calibration during extended field use.

7.4.2 After each series of field tests, the calibration of the metering system must be checked by performing three calibration measurements at a single intermediate orifice setting at or near the average used during the field testing. If the calibration has changed by more than 5%, recalibrate the meter over the full range of orifice settings. Calculations for the test series should then be performed using whichever calibration results in the lower value for total sample volume.

7.5 Probe heater: The probe heating system shall be calibrated before each initial use in the field and checked after each series of field tests according to the procedure outlined in APTD-0576.

7.6 Thermocouples: Each thermocouple must be permanently and uniquely marked on the casing; all mercury-in-glass reference thermometers must conform to ASTM-E-1 #63C or 63F specifications. Thermocouples should be calibrated in the laboratory without the use of extension leads. If extension leads are used in the field, the thermocouple reading at ambient air temperatures, with and without the extension lead, must be noted and recorded. Correction is necessary if the use of an extension lead produces a change greater than 1.5%. Calibration for the various kinds of thermocouples proceeds as follows:

7.6.1 **Impinger and organic module thermocouples:** For the thermocouples used to measure the temperature of the gas leaving the impinger train and the XAD-2 resin bed, a three-point calibration at ice water, room-air, and boiling-water temperatures is necessary. Accept the thermocouples only if the readings at all three temperatures agree within 2°C (3.6°F) of the absolute value of the reference thermometer.

7.6.2 **Dry-gas-meter thermocouples:** For the thermocouples used to indicate the dry-gas-meter inlet and outlet temperatures, a three-point calibration at ice-water, room-air, and boiling-water temperatures must be performed. The values must be within 2°C (3.6°F) of the absolute reference thermometer value at all three calibration points.

7.6.3 **Probe and stack thermocouple:** For the thermocouples used to indicate the probe and stack temperatures, a three-point calibration at ice-water, boiling-water, and boiling cooking-oil temperatures must be performed; it is highly recommended that room-air temperature be added as a fourth calibration point. If the absolute values of the reference thermometer and the thermocouple agree within 1.5% at each of the calibration points, a calibration curve (equation) may be constructed (calculated), and the data extrapolated to cover the entire temperature range suggested by the manufacturer.

7.7 Barometer: Adjust the field barometer initially and before each test series to agree within 2.5 mm Hg (0.1 in. Hg) of the mercury barometer, or within the station barometric pressure value reported by a nearby National Weather Service station and corrected for elevation.

7.8 Triple-Beam Balance: Calibrate the triple beam balance before each test series using Class-S standard weights; the weights must be within 0.5 g of the standards, or the balance adjusted to meet these limits.

7.9 Analytical Balance: Calibrate the analytical balance with Class-S weights before initially tare-weighing each set of filters. The balance must agree or be adjusted to within 2 mg of the standards. Run at least one standard each time one or more of the filters is reweighed.

8.0 CALCULATIONS

8.1 Dry gas volume:

8.1.1 From the SASS run sheet, average the dry-gas-meter temperatures and orifice pressure drops readings throughout the run. Calculate the Volume of Dry Gas Sampled at standard conditions (20°C, 760 mm Hg [528°R, 29.92 in. Hg]) using the equation:

$$V_{m(std)} = V_m Y \frac{(T_{std})}{T_m} \frac{(P_{bar} + (\Delta H/13.6))}{P_{std}}$$

$$= K_1 V_m Y \frac{(P_{bar} + (\Delta H/13.6))}{T_m}$$

where:

$V_{m(std)}$ = Volume of dry gas sampled at standard conditions, dscm (dscf);

V_m = Volume of dry gas sampled at dry-gas-meter conditions, dcm (dcf);

γ = Dry-gas-meter calibration factor, dimensionless;

T_m = Average dry-gas-meter temperature, °K (°R);

T_{std} = Standard absolute temperature, °K (°R);

P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg);

P_{std} = Standard absolute pressure, mm Hg (in. Hg);

ΔH = Average orifice pressure drop during the sampling run, mm H_2O (in. H_2O); and

K_1 = 0.358°K/mm for metric units
= 17.64°R/in. Hg for English units.

8.1.2 The above equation must be modified whenever the leakage rate observed during any of the mandatory leak-checks (i.e., the post-test leak-checks or leak-checks made prior to component changes) exceeds the maximum allowed. The modification follows:

8.1.2.1 Case I (No component changes have been made during the sampling run, and the allowable leakage rate has been exceeded during the post-test leak-check): Replace V_m with the expression:

$$V_m - [(L_p - L_a)\theta]$$

where:

L_p = Leakage rate observed during post-test leak-check, m^3/min (cfm);

L_a = Maximum allowed leakage rate, 0.0014 m^3/min (0.05 ft^3/min); and

θ = Total sampling time, min.

8.1.2.2 Case II (One or more component changes made during the sampling run, and the allowable leakage rate has been exceeded

during one or more of the leak-checks prior to component changes or during the post-test leak-check): Replace V_m with the expression:

$$V_m - \sum_{i=1}^{n} \left[\theta_{i-1}(L_i - L_a) - \theta_p(L_p - L_a) \right]$$

where:

L_i = Leakage rate observed prior to "i^{th}" component change if the allowable leakage rate has been exceeded while sampling with the "i^{th}" component, m^3/min (cfm);

L_a = Maximum allowed leakage rate, 0.0014 m^3/min (0.05 ft^3/min);

θ_{i-1} = Sampling time interval between the successive component changes in which the allowable leakage rate has been exceeded, min;

L_p = Leakage rate observed during post-test leak-check, if the allowable leakage rate has been exceeded, m^3/min (cfm); and

θ_p = Sampling time interval, from the final (n^{th}) component change until the end of the sampling run, if the allowable leakage rate has been exceeded during the post-test leak-check, min.

8.2 Moisture content:

8.2.1 Calculate the Volume of Water Vapor at standard conditions:

$$V_{w(std)} = \left[\frac{\rho_w}{M_w} \right] \left[\frac{RT_{std}}{P_{std}} \right] = K_2 V_{lc}$$

where:

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, dscm (dscf);

V_{lc} = Volume of liquid collected in the condensate reservoir added to the net increase in impinger solution volumes and silica gel weight gain during the run, mL;

ρ_w = Density of water, 0.9982 g/mL (0.002201 lb/mL);

M_w = Molecular weight of water, 18.0 g/g-mole (lb/lb-mole);

R = Ideal gas constant, 0.06236 mm Hg-m^3/°K-g-mole (21.85 in. Hg-ft^3/°R-lb-mole);

T_{std} = Standard absolute temperature, °K (°R);

P_{std} = Standard absolute pressure, mm Hg (in. Hg); and

K_2 = 0.001333 m^3/mL for metric units
= 0.04707 ft^3/mL for English units.

8.2.2 Calculate the Stack Gas Moisture Content (equal to B_{ws} x 100 for conversion to percent):

$$\%M = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}} = B_{ws} \times 100$$

where:

B_{ws} = Proportion of water vapor in the gas stream by volume, dimensionless;

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, dscm (dscf); and

$V_{m(std)}$ = Volume of gas measured by the dry gas meter, corrected to standard conditions, dscm (dscf).

8.2.3 In saturated or water-droplet-laden gas streams, make two calculations of the moisture content, one from the total volume of liquid collected in the train and one from the assumption of saturated gas-stream conditions. Use whichever method results in the lower value. To determine the moisture content based upon saturated conditions, use the average stack gas temperature in conjunction with: (1) a psychrometric chart, correcting for difference between the chart and the absolute stack pressure; or (2) saturation vapor pressure tables.

8.3 Particulate concentration:

8.3.1 Calculate the Unit Methanol/Methylene Chloride Blank Correction for all front-half samples:

$$C_{mm} = \frac{M_{mm}}{V_{mm}\rho_{mm}}$$

where:

C_{mm} = Methanol/methylene chloride blank correction, mg/g;

M_{mm} = Mass of methanol/methylene chloride after evaporation, mg;

V_{mm} = Volume of methanol/methylene chloride used in wash, mL; and

p_{mm} = Density of 50:50 mix of methanol/methylene chloride, mg/mL (see labels on bottles).

8.3.2 Calculate the Total Methanol/Methylene Chloride Blank Weight Correction for each individual front-half sample:

$$W_{mm} = C_{mm} V_{mm} \rho_{mm}$$

where:

W_{mm} = Weight of residue in methanol/methylene chloride front-half wash, mg;

C_{mm} = Methanol/methylene chloride unit blank correction, mg/g;

V_{mm} = Volume of methanol/methylene chloride used for front-half wash, mL; and

ρ_{mm} = Density of 50:50 mixture of methanol and methylene chloride, mg/mL.

8.3.3 Calculate Total Particulate Weight:

$$W_p = (W_{pf\text{-}a} + W_{pf\text{-}b} + \ldots\ldots) + (W_{10c} + W_{3c} + W_{1c}) + (W_{pr} - W_{mm})$$

where:

W_p = Total particulate weight, mg;

$W_{pf\text{-}a+\ldots}$ = Particulate weight from filter Pf-a + Pf-b + ... ;

W_{10c}, W_{3c}, W_{1c} = Particulate weight catch from the 10-, 3-, and 1-um cyclones, respectively, mg;

W_{pr} = Weight of front-half rinse residue before blank correction, mg; and

W_{mm} = Methanol/methylene chloride blank weight correction, mg.

8.3.4 Calculate the Total Particulate Concentration:

$$C_p = (0.001\ g/mg)\ (W_p/V_{m(std)})$$

where:

C_p = Concentration of particulate material in the stack gas, g/dscm (gr/dscf);

W_p = Weight of particulate material collected during run, mg; and

$V_{m(std)}$ = Volume of gas sampled, dscm (dscf).

8.3.5 To convert the above concentration to units of gr/ft^3 or lb/ft^3 for comparison with established or projected values, the following conversion factors are useful:

From:	To:	Multiply By:
scf	m^3	0.02832
g/ft^3	gr/ft^3	15.43
g/ft^3	lb/ft	2.205×10^{-3}
g/ft^3	g/m^3	35.315

8.4 Concentration of organic material:

8.4.1 Calculate the Volumetric Flow Rate (Q_{sd}) during the run. Determine the average stack gas velocity and volumetric flow rate from actual run data in the same manner that these were calculated during preliminary determinations (see Paragraph 4.3).

8.4.2 Calculate the POHC Concentration:

$$C_{pohc} = \frac{M_{pohc}}{Q_{sd}} = \frac{M_{cd\text{-}le} + M_{mrx}}{Q_{sd}}$$

where:

C_{pohc} = Concentration of POHCs in stack gas, ug/dscm;

M_{pohc} = Total mass of POHCs collected in XAD-2 and organic module rinse, and in the condensate extract, ug;

$M_{cd\text{-}le}$ = Mass of POHCs extracted from the condensate (corrected for methylene chloride blank extraction residue), ug;

M_{mrx} = Mass of POHCs extracted from the XAD-2 sorbent and organic module rinse (corrected for methylene chloride blank extraction residue), ug; and

Q_{sd} = Volumetric flow rate during the run, dscm.

8.5 Isokinetic variation:

8.5.1 Having calculated T_s, $V_{m(std)}$, V_s, A_n, P_s, and B_{ws}, determine the Isokinetic Variation using the equation:

$$I = K_4 \frac{T_s V_{m(std)}}{P_s V_s A_n \theta (1-B_{ws})}$$

where:

I = Isokinetic variation, %;

T_S = Absolute average stack gas temperature, °K (°R);

$V_{m(std)}$ = Volume of gas sampled, dscm (dscf);

P_S = Absolute stack gas pressure, mm Hg (in. Hg);

V_S = Stack gas velocity, m/sec (ft/sec);

A_n = Cross-sectional area of nozzle, m^3 (ft^3);

θ = Net sampling time, min;

B_{ws} = Proportion of water vapor in gas stream by volume, dimensionless; and

K_4 = 4.320 for metric units
= 0.09450 for English units.

8.5.2 For the accuracy of Level 1 requirements (factor of 3) for measured particulate emissions, the isokinetic variation must be within 70-150%.

8.6 Cyclone particle-size cutoff diameter:

8.6.1 The particle-size cutoff diameter represents that particle diameter (assuming spherical particles of unit density) at which the cyclone exhibits 50% collection efficiency; it is expressed as the "d_{50}." The range of particle size collected in each cyclone and on the filter is dependent upon the operating temperature and flow rate through each of

these components. The particle-size cutoff diameters of 10, 3, and 1 um in the cyclones are the result of calibration of these at 400°F and 4.0 scfm (6.5 acfm). When the determined isokinetic sampling rate is not 4.0 scfm, or when it is necessary to maintain a constant subisokinetic sampling rate (still within the limits of Level 1 accuracy) during the SASS run, the particle-size cutoff diameters for the cyclones must be extrapolated.

8.6.2 Existing calibration data is insufficient to determine exact mathematical relationships for variations of particle-size cutoff diameter with temperature and with volumetric flow rate. The best estimates (McCain, 1983) suggest that a square, and an inverse square root dependence, respectively, exist; the extrapolation equation is presented below.

8.6.2.1 Calculate the Gas Viscosity from the equation:

$$\mu = (1.68 \times 10^{-4}) + (2.292 \times 10^{-7})\ (T)$$

where:

μ = Gas viscosity, poise; and

T = Gas temperature, °F.

8.6.2.2 Extrapolate the Particle Size Cutoff Diameter from:

$$D_{T_a,F_a} = D_{400,4.0} \frac{\left[\frac{\mu_{400}}{\mu_{T_a}}\right]^2}{\left[\frac{V_{4.0}}{V_{F_a}}\right]^{1/2}} = D_{400,4.0} \frac{3.37\sqrt{V_{F_a}}}{\mu^2 T_a}$$

where:

D_{T_a,F_a} = Particle size cutoff diameter at cyclone operating a temperature and flow rate, um (note that the volumetric flow rate must be corrected to standard conditions);

$D_{400,4.0}$ = Particle size cutoff diameter at an operating temperature of 400°F and flow rate of 4.0 scfm, um;

μ_{400} = Gas viscosity at 400°F, poise;

μT_a = Gas viscosity at operating conditions, poise;

$V_{4.0}$ = Cyclone volumetric flow rate of 4.0 scfm; and

V_{F_a} = Cyclone volumetric flow rate at operating conditions, scfm.

This equation reduces to:

1. $$\frac{33.7\sqrt{V_{F_a}}}{\mu T_a^2}$$ **for the 10-um cyclone,**

2. $$\frac{10.1\sqrt{V_{F_a}}}{\mu T_a^2}$$ **for the 3-um cyclone,**

3. $$\frac{3.37\sqrt{V_{V_a}}}{\mu T_a^2}$$ **for the 1-um cyclone,**

8.7 Cumulative particulate weight percent less than calculated size:

8.7.1 Divide the weight collected in the individual cyclones and on the filter by the total weight of particulate collected; express these as a percentage, using the following equations:

$$\% W_{pf} = \frac{W_{pf\text{-}a} + W_{pf\text{-}b} + \ldots}{W_p} \times 100$$

$$\% W_{10c} = \frac{W_{10c}}{W_p} \times 100$$

$$\% W_{3c} = \frac{W_{3c}}{W_p} \times 100$$

$$\% W_{1c} = \frac{W_{1c}}{W_p} \times 100$$

where:

W_p = Total particulate weight collected, mg;

$W_{pf} = W_{pf-a} + W_{pf-b} + \ldots$

= Particulate weight collected on filters PF-a + PF-b, etc., mg;

W_{10c} = Particulate weight collected in 10-um cyclone, mg;

W_{3c} = Particulate weight collected in 3-um cyclone, mg;

W_{1c} = Particulate weight collected in 1-um cyclone, mg; and

100 = Conversion to percent.

8.7.2 Calculate the Cumulative Weight Percent Less than the Calculated Particle Size Cutoff Diameter by adding, to each weight percent, the weight percent of all fractions having a smaller particle- size cutoff diameter. Tabulate the data, using the form below as an example:

PRESENTATION OF SASS PARTICLE SIZING DATA

Stage	Weight % Collected in Stage	Cumulative Weight % Less than Calculated Particle Size Cutoff Diameter	Calculated Particle Size Cutoff Diameter
10-um cyclone			
3-um cyclone			
1-um cyclone			
Glass fiber filter

METHOD 0023A

SAMPLING METHOD FOR POLYCHLORINATED DIBENZO-*p*-DIOXINS AND POLYCHLORINATED DIBENZOFURAN EMISSIONS FROM STATIONARY SOURCES

1.0 SCOPE AND APPLICATION

1.1 This method describes the sampling procedure to be used for determining stack emissions of polychlorinated dibenzo-*p*-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) from stationary sources. The air sample is collected and analyzed by the determinative portion of Methods 8280 or 8290. This method describes the procedures for sampling and calculating results. This method may be modified to allow simultaneous sampling and analysis for polychlorinated biphenyls (PCBs), polynuclear aromatic hydrocarbons (PAHs), or semivolatile organic compounds (SVOCs). However, specific approval is required for this modification, and detailed modification of the methodology is required.

1.1.1 This method is a revision of Method 23 (see Ref. 10).

1.1.2 The surrogates and recovery standards include the standards listed in Methods 8280 and 8290.

1.1.3 The method refers to specific techniques described in Methods 1, 2 and 5 (see Ref. 10). Analysts should obtain copies of those methods prior to sampling.

1.2 This method is restricted to use by or under the supervision of analysts experienced in the use of air sampling methods and the analysis of PCDDs, PCDFs, PCBs, PAHs, and SVOCs from the components of Method 0010 trains. Each analyst must demonstrate the ability to generate acceptable results with this method.

1.3 Safety - The laboratory should develop a strict safety program for the handling of PCDDs and/or PCDFs.

1.3.1 2,3,7,8-TCDD has been found to be acnegenic, carcinogenic, and teratogenic in laboratory animal studies. Other PCDDs and PCDFs containing chlorine atoms in positions 2,3,7,8 are known to have toxicities comparable to that of 2,3,7,8-TCDD. The analyst must be aware of the potential for inhalation and ingestion. It is recommended that such samples be processed in a confined environment, such as a hood or a glove box. Personnel handling these types of samples should wear masks fitted with charcoal filters to prevent the inhalation of airborne particulates.

1.3.2 The toxicity or carcinogenicity of each reagent used in this method is not precisely defined. However, each chemical should be treated as a potential health hazard, and exposure to these chemicals kept to a minimum. The laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets should be made available to all personnel involved in the sampling and chemical analysis of samples suspected to contain PCDDs/PCDFs. Method 8290 and References 7, 8, and 9 give additional information on laboratory safety.

2.0 SUMMARY OF METHOD

2.1 Gaseous and particulate PCDDs/PCDFs are isokinetically withdrawn from an emission source and collected in a multicomponent sampling train. The collection components consist of the front half glassware surfaces (nozzle, probe, and front half filter holder), the glass fiber filter, the back half glassware surfaces (back half filter holder and condenser coil) and the solid sorbent (XAD-2®) module.

2.2 Following sampling the glass collection components are rinsed. The PCDD/PCDF are then extracted from the front half rinses and filter and another separate extraction is performed on the XAD-2® and back half rinses.

2.3 The filter and XAD-2® extracts are then analyzed separately. Surrogate recoveries are determined for both fractions. The analysis is performed using high resolution gas chromatography (HRGC) and high resolution mass spectrometry (HRMS), using the procedures of Method 8290.

3.0 INTERFERENCES

3.1 The use, in this method, of high resolution mass spectrometry with high resolution capillary gas chromatography avoids the interference from polychlorinated biphenlys and polychlorinated diphenyl ethers which could be serious with lower resolution techniques.

3.2 Very high amounts of other organic compounds in the matrix will interfere with the analysis. Extensive column-chromatographic cleanup has been introduced into typical HRGC/HRMS analytical methodology to minimize matrix effects due to high concentrations of organic compounds.

3.3 Method interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing hardware. All of these materials must be routinely demonstrated to be free from interferences under the conditions of the analysis by preparing and analyzing laboratory method blanks.

Glassware must be cleaned thoroughly before using. A procedure which has been found to be effective is given in Sec. 6.1.4, but any protocol which consistently results in contamination-free glassware is acceptable.

3.3.1 The use of high purity reagents and solvents helps to minimize interference problems in sample analysis.

4.0 APPARATUS AND MATERIALS

The following section describes all the sampling equipment and the associated performance specifications necessary to collect a gas sample from a stationary source according to Method 0023.

4.1 Sampling train - A schematic diagram of the sampling train is shown in Figure 1. This train configuration has been adapted from Method 5 (Reference 10) with the addition of condenser, XAD-2® trap and filtration-coil connecting glassware. Sealing greases must not be used in assembling the train. Complete sampling systems are commercially available that have been developed to meet all the EPA equipment design specifications. The following equipment is required.

4.1.1 Nozzle - The nozzle should be made of quartz or borosilicate glass. Stainless steel nozzles should not be used. The taper angle should be ≤ 30°, with taper on the outside to preserve a constant inside diameter (ID). The nozzle ID should be determined in order to sample isokinetically at a rate that allows collection of an adequate sample volume. The minimum sample volume should be determined to allow appropriate detection limits to be achieved (see Sec. 6.2.3).

4.1.2 Probe liner - The sampling probe liner should be constructed of borosilicate or quartz glass tubing. The typical outside diameter (OD) used by sampling equipment manufacturers is about 16 mm, encased in a stainless steel sheath with an OD of 25.4 mm. Either borosilicate or quartz glass liners may be used for stack temperatures up to about 480°C, but quartz glass liners should be used at higher stack temperature [480 to 900°C].

4.1.3 Probe sheath and heating system - A stainless steel or equivalent probe sheath should be used to house the probe liner and heating system. The probe heating system should be capable of maintaining probe gas temperatures at the probe exit of 120°C ± 14°C during sampling. This temperature should be verified by placing a thermocouple temperature sensor against the outer surface of the probe liner at least 2 feet upstream of the filter oven. Temperature readings should be recorded during sampling.

4.1.4 Glass cyclone - A glass cyclone may be used between the probe and filter holder for high particulate concentrations. A cyclone, if used, should be rinsed and recovered with the front half of the train.

4.1.5 Filter holder - A filter holder of borosilicate glass with a Teflon® frit filter support should be used. The holder design should provide a positive seal against leakage from the outside or around the filter. The holder should be durable, easy to load, leak-free in normal applications, and is positioned immediately following the probe (or cyclone, if used) with the filter placed toward the flow.

4.1.6 Filter heating system - Any heating system may be used which is capable of maintaining the filter holder at 120°C ± 14°C during sampling. Other temperatures may be specified by a subpart of the regulations or approved for a particular application. A gauge capable of measuring temperatures to within 3°C should be provided to monitor the temperature around the filter during sampling.

4.1.7 Sample transfer lines - A sample transfer line may be used if needed to direct sample flow from the probe to the filter or from the filter to the condenser. The probe-to-filter line should be insulated and heated so that gas exit temperatures are 120°C ± 14°C. The filter-to-condenser line should be insulated and oriented with the downstream end lower than the upstream end so that any condensate will flow away from the filter and into the condenser. These lines should be constructed of Teflon® or glass and should be recovered with their respective rinse fractions (front half or back half).

4.1.8 Condenser - A multi-coil water-cooled glass condenser should be used to cool the sample gas prior to entry into the sorbent module. The orientation of the condenser should be vertical.

4.1.9 Sorbent module - The glass water-cooled container configured to hold the solid sorbent (XAD-2®) should contain a minimum of 20 g of XAD-2® and may contain as much as 40 g. A schematic diagram is shown in Figure 2. A single piece condenser-trap can be used if desired. The sorbent trap configuration should be vertical so that condensate drains from

the condenser through the sorbent and so that channeling of the gas flow does not occur. The connecting fittings should form leak-free, vacuum tight seals. Sealant greases should not be used in the sampling train. A coarse glass or Teflon® frit along with glass wool plugs is included to retain the sorbent. The tester may engrave a unique identification number for inventory and sample tracking.

4.1.10 Impinger trains - Four impingers should be connected in series with leak-free ground-glass fittings or any similar noncontaminating fittings. The first impinger should be a short stem (knock out) version. The second impinger should be a Greenburg-Smith impinger with the standard tip and plate. The third and fourth impingers should be the Greenburg-Smith design modified so that the glass tube has an unconstricted 13 mm ID and extends to within 13 mm of the flask bottom. The fourth impinger outlet connection should allow insertion of a thermometer capable of measuring ± 1°C of true value in the range of 0 to 25°C.

4.1.11 Water circulating bath - A bath and pump circulating system which is capable of providing chilled water flow to the condenser and sorbent trap water jackets should be used. Typically a submersible pump is placed in the impinger ice water bath so that the ice water contained there can be used. The function of this system should be verified by measuring sorbent trap gas entrance temperature $\leq$20°C.

4.1.12 Pitot tube - The pitot tube, preferably of Type S design, shall meet the requirements of Method 2. The pitot tube is attached to the probe as shown in Figure 1. The proper pitot tube-sampling nozzle configuration for prevention of aerodynamic interference is shown in Figures 2.6 and 2.7 of Method 2. The Type S pitot tube assembly shall have a known coefficient, determined as outlined in Sec. 4 of Method 2.

4.1.13 Differential pressure gauge - The differential pressure gauge should be an inclined manometer or the equivalent as described in Method 2. Two gauges are required: one gauge to monitor the stack velocity pressure (ΔP), and the other to measure the orifice pressure differential (ΔH).

4.1.14 Metering system - The metering system should consist of a dry gas meter with 2% accuracy, a vacuum pump, a vacuum gauge, orifice meter, thermometers or thermocouples capable of measuring ± 3°C of true value in the range of 0 to 90°C; and related equipment as shown in Figure 1. Thermocouples should be used to monitor the temperature at the following sampling train locations:

- stack gas
- probe liner
- filter holder
- sorbent trap entrance
- silica gel impinger exit
- dry gas meter inlet and
- dry gas meter outlet.

Other metering systems capable of maintaining isokinetic sampling rates within 10% and determining sample volumes to within 2% may be used if approved. Sampling trains with metering systems designed for sampling rates higher than those described in APTD-0581 and APTD-0576 (Air Pollution Technical Document, see references) may be used if the above specifications can be met. When the metering system is used with a pitot tube, the system should permit verification of an isokinetic sampling rate through the use of a nomograph or by calculation.

4.1.15 Barometer - A mercury (Hg), aneroid, or other barometer capable of measuring atmospheric pressure to within ± 2.5 mm Hg is needed. A preliminary check of a new barometer should be made against a mercury-in-glass barometer or the equivalent. The absolute barometric pressure may be obtained from a nearby weather service station and adjusted for elevation difference between the station and the sampling point. Either subtract 2.5 mm Hg from the station value for every 30 m elevation increase or add the same for an elevation decrease. If the barometer cannot be adjusted to agree within 0.1 in. Hg of the reference barometric pressure, it should be repaired or discarded.

4.1.16 Gas density determination equipment - The equipment necessary for conducting Methods 2 - 4 for determining stack gas flow, molecular weight and moisture content, respectively, should be used. Required measurements include stack gas velocity and static pressure; gas temperature; concentrations of O_2, CO_2, and N_2 (by difference), metered gas volumes and meter temperatures and pressure; and condensate weight gain collected by the impinger train. All equipment should meet Methods 2 through 4 requirements.

4.2 Sample recovery equipment

4.2.1 Fitting caps - Ground glass or cleaned aluminum foil to cap the exposed sections of the train.

4.2.2 Wash bottles -Teflon® .

4.2.3 Probe-liner, probe-nozzle, and filter-holder brushes - These should be constructed with nylon or Teflon® bristles with precleaned stainless steel or Teflon® handles. The probe brush should have extensions of stainless steel or Teflon® at least as long as the probe. The brushes should be properly sized and shaped to brush out the nozzle, probe liner, and front half filter holder.

4.2.4 Filter storage container - Typically a glass petri dish sealed with Teflon® tape is used. Petri dishes should be cleaned according to glassware cleaning procedures listed in this method (Sec. 6.1.4).

4.2.5 Balance - This balance is used for measuring weight gain of the impingers and sample bottle weights as well. Typically a 0 to 2000-g balance is used. The balance should be accurate to within 0.5 g, verified with ASTM Class 1 (Class S) weights.

4.2.6 Aluminum foil - Heavy duty cleaned by rinsing three times with methylene chloride and once with toluene, stored in pre-cleaned glass petri dish or glass jar.

4.2.7 Graduated cylinder - Glass, 250-mL, with ± 1 mL resolution (this cylinder can be used for impinger volume determinations in place of the balance).

4.2.8 Glass sample storage container - Amber glass bottle for sample glassware washes, 500- or 1000-mL, with leak-free Teflon® -lined caps. The bottles should be either purchased as precleaned or cleaned according to glassware cleaning procedures listed in this method (Sec. 6.1.4).

5.0 REAGENTS

5.1 Filters - Glass fiber filters, without organic binder, exhibiting at least 99.95% efficiency (< 0.05% penetration) on 0.3 µm dioctyl phthalate smoke particles. One filter from each batch is tested for contamination using the procedure in Sec. 5.1.2. If the filter fails the test, then all filters must be cleaned and retested before their initial use according to the following procedures.

5.1.1 Precleaning - Place no more than 50 filters in a Soxhlet extraction apparatus. Charge the Soxhlet with toluene and reflux for 16 hours. After extraction, allow the Soxhlet to cool. Remove the filters and dry under a clean nitrogen (N_2) stream. Store the filters in cleaned glass petri dishes or amber glass bottles sealed with Teflon® tape or Teflon® -lined caps prior to using them.

5.1.2 As a quality control check prior to the field test, take one precleaned filter and perform Soxhlet extraction with toluene for 16 hours. Remove the toluene extract and analyze according to Method 8290. No analytes may be observed above the detection limit.

5.1.3 Filter surrogate spike solution - As stated in Sec. 7.3.3, this method calls for both the filter and the XAD-2® sorbent to be spiked with the same set of isotopically labeled PCDD/PCDF standards. Surrogate spikes are added to the sorbent prior to sampling and to the filter immediately before the sample extraction. The filter and XAD-2® fractions (including the associated glassware rinses) are extracted separately and analyzed separately. The surrogate standards listed in Table 1 should be used for both the filter spike and sorbent spike.

5.1.4 To ensure proper filter spiking, the isotopically-labeled standard solution, which is normally at a concentration of 0.1 ng/µL, is diluted to 0.004 ng/µL with nonane, for a dilution factor of 25. This spiking solution will be used to spike the surface of the filter as discussed in Sec. 7.3.1.

5.2 Sorbent resin - Amberlite XAD-2® resin. XAD-2® may be purchased precleaned or cleaned by the laboratory. If the sorbent has not been precleaned, a cleaning procedure capable of producing resin meeting the quality control check in Sec. 5.2.1.8 shall be implemented. The procedure given below has been found to produce excellent results.

5.2.1 Sorbent resin cleaning procedure

5.2.1.1 Place the sorbent resin in a clean beaker and rinse with reagent water. Discard the rinse. Fill the beaker a second time with reagent water and allow the resin to stand overnight. Discard this second rinse.

5.2.1.2 Place the sorbent resin in an all-glass thimble of a large Soxhlet extractor. The sorbent resin will float when in contact with methylene chloride. Therefore, add a glass wool plug on top of the resin in the thimble, and weight the glass wool plug down with a stainless steel ring that fits inside the thimble.

5.2.1.3 Place the thimble filled with resin into the Soxhlet extractor, add organic-free reagent water to the distilling flask, apply heat, and extract the resin for 8 hours.

5.2.1.4 Allow the Soxhlet extractor to cool, discard the water, and add methanol to the extractor. Apply heat and extract for 22 hours.

5.2.1.5 Again allowing the extractor to cool, drain off the methanol, replace it with methylene chloride. Make sure that the stainless steel ring and glass wool plug are still in place and extract for 22 hours.

5.2.1.6 Extract the resin a fourth time, using toluene as the extraction solvent, for 22 hours.

5.2.1.7 Following the toluene extraction, the sorbent resin must be dried under a stream of clean dry nitrogen or other inert gas. This may be accomplished by transferring the resin to a large diameter glass column and flowing the gas through the column. The gas may be heated to less than 40°C, using a steam bath or other appropriate heat source. Continue the inert gas flow through the resin until all the residual solvent is removed. The flow rate should be sufficient to agitate the resin particles, but not so excessive as to cause the particles to fracture.

5.2.1.8 A quality control check should be conducted on the cleaned sorbent using HRGC/HRMS techniques (Method 8290). Typically, a method blank conducted previously on the same lot of sorbent can serve this purpose.

5.2.2 Sorbent resin surrogate spike solution - The-XAD-2® sorbent is spiked with isotopically labeled PCDD/PCDF standards prior to sampling (surrogate spikes).

5.3 Glass wool - Cleaned by sequential immersion in three aliquots of methylene chloride and one aliquot of toluene, dried in a 110°C oven, and stored in a toluene-washed glass jar with a Teflon® -lined screw cap.

5.4 Organic-free reagent water - All references to water in this method refer to organic-free reagent water as defined in Chapter One.

5.5 Silica gel - Indicating type, 6 to 16 mesh. If previously used, dry at 175°C for two hours. New silica gel may be used as received. Alternatively, other types of desiccants may be used, provided that appropriate performance has been demonstrated.

5.6 Recovery solvents - Solvents must be pesticide quality or equivalent.

5.6.1 Acetone, CH_3COCH_3

5.6.2 Methylene chloride, CH_2Cl_2

5.6.3 Toluene, $C_6H_5CH_3$

6.0 SAMPLING COLLECTION, PRESERVATION, AND PREPARATION

This section addresses preparation and collection procedures for sampling.

6.1 Laboratory preparation

6.1.1 Filters. (See Sec. 5.1.)

6.1.2 Sorbent trap. (See Sec. 5.2.)

6.1.3 Glass wool - Precleaning and storage. (See Sec. 5.3.)

6.1.4 Glassware - All glass components of the train should be cleaned thoroughly. The following procedure has been found to be effective, but any protocol which consistently results in contamination-free glassware is acceptable.

Soak all glassware in hot soapy water (Alconox® or equivalent).
Rinse with tap water to remove soap.
Rinse with distilled/deionized H_2O (three times).
Bake at 400°C for 2 hours.
Rinse with methylene chloride (pesticide grade) (three times).
Rinse with toluene (pesticide grade) (three times).
Cap glassware with clean glass caps or cleaned aluminum foil.
Mark cleaned glassware with color-coded identification stickers.
Rinse glassware immediately before using with acetone and methylene chloride.

6.1.5 Because probe liners do not usually fit in glassware baths or ovens, they may be rinsed three times with methylene chloride followed by three rinses with toluene, and sealed during transport.

6.2 Preliminary field determinations

6.2.1 Sample site - The sampling site and the minimum number of sampling points should be selected according to Method 1 or as specified by the Agency. The stack static pressure, temperature, and range of velocity pressures (ΔPs) should be determined using Method 2. The stack gas moisture content should be determined using Method 4, its alternatives, previous data, or an engineering estimate. Stack gas O_2 and CO_2 concentrations should be estimated and dry molecular weight should be calculated. These parameters are used to estimate the isokinetic sampling rate settings.

6.2.2 Nozzle size - The nozzle size should be based on the range of velocity pressures so that it is not necessary to change the nozzle size in order to maintain isokinetic sampling rates.

6.2.3 Sampling duration - The total length of sampling time needed to obtain the identified minimum sample gas volume is determined by comparing the anticipated average sampling rate with the volume requirement. (Average sampling rate should be within 0.5 to 0.75 cfm.) The same time should be allocated to all traverse points defined by Method 1. To avoid timekeeping errors, the length of time sampled at each traverse point should be an integer or an integer plus one-half minute.

6.2.3.1 Calculation of length of the sampling duration - The minimum sampling time required to achieve a minimum sample volume and the corresponding detection limit (DL) are given below.

$$\text{Minimum sample time} = \frac{\text{analytical DL}}{\text{(Sample Rate) x (desired gas conc. DL)}}$$

6.2.3.2 The following calculation is for a single isomer (i.e., 2,3,7,8-TCDF). Detection limits for other isomers may need to be calculated as well. For this example, it will be assumed that the analytical detection limit is 0.5 ng (actual analytical detection limit will need to be specified for each test program).

6.2.3.3 At a sampling rate of 0.014 m^3/min (0.5 cfm), the sample volume per hour will be 0.85 m^3/h. Assuming a desired stack gas concentration detection limit to be 0.1 ng/m^3, the minimum sample time required to collect 0.5 ng at concentration in the stack of 0.1 ng/m^3 would be:

$$\text{Minimum sample time} = \frac{0.5 \text{ ng}}{0.85 \text{ m}^3\text{/h} \times 0.1 \text{ ng/m}^3} = 6.25 \text{ h}$$

6.2.3.4 The total sampling time should be greater than or equal to the minimum total sampling time required to achieve the necessary detection limit. In addition, the sampling time per point should be greater than 2 min (greater minimum time interval may be specified by the Agency), and the sample volume corrected to standard conditions shall exceed the required minimum total gas sample volume.

6.3 Calibration

Calibration of the apparatus is one of the most important functions in maintaining data quality. The detailed calibration procedures for the sampling apparatus listed in this section can be found in Method 5 and Method 0010. Table 4 summarizes the quality assurance functions for the calibrations.

6.3.1 Metering system

6.3.1.1 Full dry gas meter calibration - The dry gas meter (DGM) in the meter console of the sampling system should be fully calibrated against a primary standard meter (wet test meter or spirometer) or alternatively against a second reference meter (dry gas meter or critical orifice) that has been calibrated against a primary standard meter. The procedure can be found in Method 5.

6.3.1.2 Post-test DGM calibration check - Following the test program, the full calibration factor or meter Y should be checked by performing a post-test DGM calibration check. Any secondary reference meters can be used. Three calibration runs are conducted at the maximum vacuum reached during the testing. The average post-test calibration factor should not deviate from the full DGM calibration factor by more than 5%. Additional details on these procedures can be found in Method 5.

6.3.2 Temperature gauges - Each thermocouple should be permanently and uniquely marked on the casting; all mercury-in-glass reference thermometers should conform to ASTM E-1 63C or 63F specifications. Thermocouples should be calibrated in the laboratory with and without the use of extension leads. If extension leads are used in the field, the thermocouple readings at ambient air temperatures, with and without the extension lead, should be noted and recorded. Correction is necessary if the use of an extension lead produces a change greater than 1.5 percent.

6.3.2.1 Impinger, organic module, and dry gas meter thermocouples - For the thermocouples used to measure the temperature of the gas leaving the impinger train and the XAD-2® resin bed, three-point calibration at ice-water, room-air, and boiling-water temperatures is necessary. The thermocouples should be accepted only if the readings at all three temperatures agree to ± 2°C with those of the absolute value of the reference thermometer.

6.3.2.2 Probe and stack thermocouple - For the thermocouples used to indicate the probe and stack temperatures, a three-point calibration at ice-water, boiling-water, and hot-oil-bath temperatures should be performed; it is recommended that room-air temperature be added, and that the thermometer and the thermocouple agree to within 1.5% at each of the calibration points. A calibration curve (equation) may be constructed and the data extrapolated to cover the entire temperature range suggested by the manufacturer.

6.3.3 Probe heater - The probe heating system should be calibrated prior to field use according to the procedure outlined in APTD-0576. Probes constructed according to APTD-0581 need not be calibrated if the curves of APTD-0576 are used.

6.3.4 Barometer - The field barometer should be adjusted initially and before each test series to agree within 2.5 mm Hg of the mercury-in-glass barometer or with the station pressure value reported by a nearby National Weather Service station, corrected for elevation. The correction for elevation difference between the station and the sampling point should be applied at a rate of -2.4 mm Hg/30 m of elevation increase. The results should be recorded on the pretest sampling check form.

6.3.5 Probe nozzle - Probe nozzles should be calibrated before initial use in the field. The ID of the nozzle should be measured with a micrometer to the nearest 0.025 mm. Three measurements should be made using different diameters each time and the average obtained. The difference between the high and the low numbers should not exceed 0.1 mm. When nozzles become damaged they should not be used again. Each nozzle should be permanently and uniquely identified.

6.3.6 Pitot tube - The Type S pitot tube assembly should be calibrated using the procedure outlined in EPA Method 2.

6.3.7 Balance - The balance should be calibrated initially by using ASTM Class 1 (Class S) standard weights and should be within 0.5 g of the standard weight.

6.4 Sampling train preparation - Care should be taken to ensure a clean sampling train preparation area free of excessive dust and organic compounds for preparing the sampling train.

6.4.1 Preparation of impingers - During preparation and assembly of the sampling train, all train openings where contamination can enter should be sealed until just prior to assembly or until sampling is about to begin.

6.4.1.1 The first impinger should be left empty (used as a water knock-out impinger due to long run times).

6.4.1.2 Approximately 100 mL of reagent water should be placed in the second and third impingers. This method does not require that organic analyses be conducted on the impinger contents. However, if analyses of semivolatile organic compounds are to be conducted, then the proper specifications on cleaning the impingers and water quality (i.e., HPLC-grade water) should be observed.

6.4.1.3 Approximately 200 to 300 g of silica gel should be placed in the fourth impinger. All impingers should be weighed separately to the nearest 0.5 g and the weights recorded. Impingers should be connected with glass U-tube connectors.

6.4.2 Filter loading - A filter should be placed in a properly-cleaned filter holder using cleaned tweezers or clean disposable surgical gloves. The filter should be properly centered and the gasket (if used) properly placed to prevent the sample gas stream from circumventing the filter. The filter should be checked for tears after the assembly is completed.

6.4.3 Sorbent loading - The XAD-2® should be loaded and sealed in the analytical (preparation) laboratory.

6.4.4 Final assembly - The final assembly of the filter holder, condenser, and sorbent module can be performed at the stack location. All components should be sealed with either precleaned foil or socket joints.

6.5 Sampling train leak check procedures - Leak checks are necessary to assure that the sample has not been biased low by dilution air. Both pre-test and post-test leak checks are necessary.

6.5.1 Pre-test - After the sampling train has been assembled, the train should be leak checked at the sampling site by plugging the nozzle and pulling a 380 mm Hg vacuum. Leakage rates greater than 4% of the average sampling rate or 0.00057 m^3/min, whichever is less, are unacceptable. Leak checks should be conducted according to Method 5 criteria.

6.5.2 During the sampling - If a component (e.g., filter assembly, sorbent module, or impinger) change is necessary during the sampling run, a leak check should be conducted before the change. The leak check should be done according to the procedure outlined above, except that it should be at a vacuum equal to or greater than the maximum value recorded up to that point in the test. If the leakage is less than 0.00057 m^3/min or 4% of the average sampling rate (whichever is less), the results are acceptable. If, however, a higher leakage rate is obtained, the tester should record the leakage rate and either void the sampling run or perform sample volume leak corrections (if approved by the Agency). After replacing the train component, an initial leak check should be completed before sampling.

6.5.3 Post-test - The leak check should be completed at a vacuum equal to or greater than the maximum value reached during the sampling run. If the leakage rate is less than 0.00057 m^3/min or 4% of the average sampling rate (whichever is less), the results are acceptable. If, however, a higher leakage rate is obtained the tester shall either void the sample run or perform sample volume leak corrections (if approved by the Agency).

6.6 Sampling train operation

6.6.1 Final pre-test sampling checks - After conducting the initial leak check, the following checks should be made:

- Meter box examination
- Manometers leveled and zeroed
- Pump checked for proper operation
- Pitot lines leak checked
- Probe markings verified
- Thermocouples reading correctly
- Size and orientation of the nozzle verified
- Method 3 equipment for CO_2/O_2 checked for proper assembly and leak checked and
- Isokinetic K-factor checked to ensure that it is correct.

Immediately prior to sampling:

- Portholes should be cleaned to minimize the chance of sampling deposited material
- Probe and filter heating system temperatures should be checked
- Condenser/sorbent cooling system temperatures should be checked and
- Proper nozzle location should be verified.

6.6.2 The sampling procedure below should be followed.

6.6.2.1 Sampling - Initial dry gas meter readings, barometric pressure, and temperatures should be recorded. The tip of the probe should be positioned at the first sampling point with the nozzle tip pointing directly into the gas stream. When the probe is in position, the open area around the probe and the porthole should be blocked off to prevent flow disturbances and non-representative dilution of the gas stream. The pump should be turned on and the sample flow adjusted immediately to attain isokinetic conditions. The Method 3 sampling system should be turned on. Velocity pressures should be recorded and the sampling rate adjusted to isokinetic. Other readings of velocity pressure (ΔP), orifice pressure (ΔH), stack gas temperature (T_s), probe temperature (T_p), filter temperature (T_f), sorbent trap temperature (T_t), silica gel impinger temperature (T_{sg}), dry gas meter inlet and outlet temperatures (T_m), dry gas meter volume, and sample vacuum should be made.

6.6.2.2 The stack should be traversed as directed in Method 5 procedures. At each sample point, the above readings should be taken and sample flow rates adjusted to isokinetic. Following the traverses, the pump is turned off, the probe removed from the stack, and the final DGM readings recorded. Care should be taken not to bump the nozzle against stack walls in order to minimize the chance of breakage or extracting deposited material. Following each port traverse, a leak check is recommended in order to ensure a leak tight system. An additional leak check may also be performed after the train is moved to the next port, prior to sampling. The necessary post-test leak check should be conducted and the leak rate recorded.

6.6.2.3 Periodically during the test run, the connecting glassware from the probe, through the filter, and to the condenser should be checked for water condensation. If any condensation is evident, verify that the temperature sensors and heater systems are functioning properly. Ice should be maintained around the impingers to keep both the sorbent trap entrance and silica gel exit temperature at 20°C. Filter vacuum should be checked for sudden increases. The filter should be changed if the vacuum exceeds 15 in. Hg. The manometer level and zero should also be checked periodically during each traverse, because vibrations and temperature fluctuations can cause the manometer zero to shift.

6.6.2.4 Following the post-test leak check, the probe should be disconnected, and the nozzle and the end of the probe capped with precleaned aluminum foil, or equivalent caps. The inlet to the filter holder should be capped according to one of the methods previously mentioned. It may be necessary to loosen the seal between the sorbent module outlet and the inlet to the first impinger to prevent water from being drawn back into the module when the sample train cools. Alternatively, the filter holder, condenser and sorbent module may be disassembled and immediately capped at the stack location and removed to the sample recovery area.

6.7 Collection of blanks - Four different sampling blanks should be collected: field blanks, reagent blanks, proof blanks, and method blanks (laboratory only). Only two sampling blanks should be analyzed initially: the field blank and the laboratory method blank. If the field blank has high levels of contamination and the laboratory blank does not show high background levels of PCDD/PCDF, the other blanks should be analyzed to help determine the source of the contamination. Blanks are further discussed in Sec. 8.0.

7.0 PROCEDURE

7.1 Recovery preparation - Proper recovery procedure begins as soon as the probe is removed from the stack at the end of the sampling period. The nozzle end of the sampling probe should be sealed with precleaned aluminum foil and disconnected from the filter holder. When the probe is cool enough to be handled safely, all external particulate matter near the tip of the probe should be wiped off and both ends of the probe closed off with aluminum foil. Both openings to the filter holder, transfer line (if used), condenser, sorbent trap, and impinger train should be disconnected and sealed. Care should be taken not to lose any condensed water upstream of the impingers (if present) during this process.

Train components should be transferred to the cleanup area. This area should be clean and enclosed so that the chances of losing or contaminating the sample are minimized. Smoking, which could contaminate the sample, is not allowed in the cleanup area. Cleanup personnel should wash their hands prior to sample recovery. The train should be inspected prior to and during disassembly and any abnormal conditions, e.g., broken filter, colored impinger liquid, etc., noted.

7.2 Sample recovery procedure - As shown in Figure 3, the sampling train should be recovered into four containers. The procedures applicable to each sample container are briefly discussed in the following section.

7.2.1 Filter (Container 1) - The filter should be removed carefully from the filter holder and placed in its identified container. Cleaned tweezers should be used to handle the filter. Fold the filter, if necessary, with the particulate cake inside the fold. Any particulate matter and filter fibers which adhere to the filter holder gasket should be transferred to the container by using a dry inert bristle brush and a sharp-edged blade. The container should be sealed with Teflon® tape.

7.2.2 Front half rinse (Container 2) - Quantitatively recover material deposited in the nozzle, probe liner, probe transfer line, cyclone (if used), and the front half of the filter holder. Brush while rinsing three times each with acetone and then rinse three times with methylene chloride. All rinses should be put into Container 2. The outside of the probe, the pitot tube, and the nozzle should be cleaned to prevent particulates from being brushed into the sample bottle. The probe liner should be tilted and rotated while squirting acetone into the upper end to assure complete wetting of the inside surface. Acetone is then squirted into the upper end while pushing the probe brush through the liner with a twisting motion, with the drainage caught in the sample bottle (Container 2). The brushing procedure should be repeated two more times or until no particles are visible in the drainage and a visual inspection of the liner reveals no particles remaining inside. The brush should be rinsed into the sample bottle to collect any particulates that may be retained within the bristles. The three acetone rinses are followed with methylene chloride and two rinses with toluene allowing the rinsate to collect into the same sample container.

After all the rinsings have been collected, the lid on the sample container should be tightened securely. As a precaution in case of leakage, the liquid level should be marked on the sample container and the cap sealed with Teflon® tape. The sample recovery should be recorded on the sample recovery form.

7.2.3 Sorbent module (Container 3) - The sorbent module should be removed from the train, tightly capped at both ends with aluminum foil or glass caps, labeled and stored on ice for transport to the laboratory. Care should be taken to ensure that no ice water can leak into the stored traps or any other train component.

7.2.4 Back half rinse (Container 4) - Rinse the back half of the filter holder, the connecting line between the filter holder and the condenser, and the condenser itself (if separate from the trap) three times with acetone, followed by two rinses with methylene chloride and two rinses with toluene. The sample container (Container 4) is then identified and sealed as discussed above.

7.2.5 Impinger water - Any color or film in the impinger water should be noted on the sample recovery form. The entrained moisture in the first three impingers should be measured to within ± 1 mL by using a graduated cylinder or by weighing to within 0.5 g by using a balance, and the data recorded appropriately. This information is needed to calculate the moisture content of the effluent gas. If the sampling train catch is to be analyzed exclusively for dioxins and furans, then the impinger liquid may be discarded after the volume or weight is recorded.

7.2.6 Silica gel - The color of the indicating silica gel should be noted on the recovery form to determine if it has been completely spent and the impinger weighed to determine entrained moisture weight gain. Analysis is not required.

7.3 Analysis summary - The following section summarizes the analytical procedures for quantitating PCDD/PCDF collected by the sampling train. Sample preparation procedures and the basic analytical techniques are listed. The detailed analytical protocol can be found in Method 8290.

7.3.1 As shown in Figure 4, the analytical procedure requires the sampling train to be analyzed in two fractions. Containers 1 and 2 (filter and front half rinse) are combined and analyzed. Containers 3 and 4 (sorbent trap and back half rinse) are also combined and analyzed. In this way filter surrogate standard recoveries and XAD-2® surrogate standard recoveries are both determined separately.

7.3.2 Acceptance criteria and corrective actions for surrogate recoveries are as follows:

7.3.2.1 All PCDD/PCDF surrogate recoveries should be within 70 to 130 percent.

7.3.2.2 If all isomer recoveries are greater than 130 percent, the sampling runs should be repeated,

7.3.2.3 If all isomer recoveries are less than 70 percent, the sampling runs should either be repeated or the final results should be divided by the fraction of surrogate recovery.

7.3.2.4 If some of the isomer recoveries are within the acceptance range and some are not, then the final results for the isomers outside the range should be divided

by the fraction of the surrogate recovery, the resulting corrected results should be flagged in the data tables, and a discussion should be included in the final report.

7.3.2.5 Acceptance criteria for other standard recoveries (i.e., internal) should conform to Method 8290 requirements.

7.3.3 As discussed in Secs. 5.1.2 and 5.2.1, surrogate spikes are added to the sorbent trap prior to sampling and to the filter immediately prior to extraction. The same set of isotopically-labeled compounds is used for these spikes. The analytical procedure for both fractions is given in the following sections. All samples should be extracted within 30 days of collection and analyzed within 45 days of extraction.

7.3.4 Sample preparation and internal standard addition - The following procedure should be performed for the filter/front half analysis and the sorbent trap/back half analysis. The only difference between the two procedures is that surrogate standards are added to the filter/front half fraction immediately prior to sample preparation whereas the surrogate standards have already been added to the sorbent trap/back half prior to sampling.

7.3.4.1 Filter/front half fraction procedures - Place a cellulose extraction thimble, 1 g of silica gel or sodium sulfate, and a plug of glass wool into the Soxhlet apparatus, charge the apparatus with toluene, and reflux for a minimum of 3 hours. Remove the toluene and discard it, but retain the silica gel. Remove the extraction thimble from the extraction system and place it in a glass beaker to catch the solvent rinses.

7.3.4.2 Add exactly 1.0 mL of the surrogate spiking solution (Sec. 5.1.2) uniformly onto the surface of the filter while it is still in the petri dish in which it was returned from the field, using an adjustable pipet. Transfer the filter directly to the extraction thimble of the extraction system. Rinse the petri dish with 10 mL of toluene three times collecting the rinsate into the beaker.

7.3.4.3 Concentrate the sample in Container 2 (acetone/ methylene chloride rinses) to a volume of about 1-2 mL using a Kuderna-Danish concentrator apparatus, followed by nitrogen blow down at a temperature of less than 37°C. Rinse the sample container three times with small portions of methylene chloride and add these to the concentrated solution and concentrate further to near dryness. This residue contains particulate matter removed in the rinse of the train probe and nozzle. Add the concentrate to the filter in the Soxhlet apparatus described above.

7.3.4.4 Add 40 µL of the internal standard solution. Fortification is accomplished by using the sample fortification solutions described in Table 1. Cover the contents of the extraction thimble with the cleaned glass wool plug and proceed to the extraction procedure.

7.3.4.5 Sorbent trap/back half fraction procedures - Prepare another extraction thimble/silica gel system as described above. Suspend the adsorbent module directly over the extraction thimble in the beaker. The glass frit of the module should be in the up position. Using a Teflon® squeeze bottle containing toluene, flush the XAD-2® into the thimble onto the bed of cleaned silica gel. Thoroughly rinse the glass module catching the rinsings in the beaker containing the thimble, first with methanol, if needed, then with toluene into the thimble. If the resin is wet, effective extraction can be accomplished by loosely packing the resin in the thimble. Add glass wool plug from the XAD-2® sampling module to the thimble.

7.3.4.6 Concentrate the sample in Container 4 (acetone/methylene chloride rinses) to a volume of about 1 - 2 mL using a Kuderna-Danish concentrator apparatus, followed by nitrogen evaporation at a less than 37°C. Rinse the sample container three times with small portions of methylene chloride and add these to the concentrated solution and concentrate further to near dryness. Add the concentrate to the XAD-2® resin in the Soxhlet apparatus described above.

7.3.4.7 Add 40 µL of the internal standard solution. Fortification is accomplished by using the sample fortification solutions described in Table 1. Cover the contents of the extraction thimble with a cleaned glass wool plug to prevent the XAD-2® resin from floating into the solvent reservoir of the extractor and proceed with extraction (Sec. 7.3.2).

7.3.5 Sample extraction - Place the thimble in the extractor and add the toluene contained in the beaker to the solvent reservoir. Pour additional toluene to fill the reservoir approximately two-thirds full. Add Teflon® boiling chips and assemble the apparatus. Adjust the heat source to cause the extractor to cycle three times per hour. Extract the sample for 16 hours. After extraction, allow the Soxhlet to cool. Transfer the toluene extract and three 10-mL between rinses to the rotary evaporator. Concentrate the extract to approximately 10 mL.

Use a nitrogen evaporative concentrator to reduce the volume of the extract to about 100 µL. Redissolve the residue in 5 mL of hexane.

7.3.6 Sample clean-up and fractionation - Sample extracts described above are spiked with 40 µL of the alternate standard fortification solution, then divided into two equal portions. One half of each sample extract is archived for future needs. The other portion is solvent-exchanged to hexane then subjected to three column chromatographic cleanup steps as described in Method 8290.

7.3.7 Analysis summary - The samples are analyzed with a high resolution gas chromatographic column coupled to a high resolution mass spectrometer (HRGC/HRMS) using the instrumental parameters described below. Prior to analysis, the Recovery Standard solution from Table 1 is added to each sample. Sample extracts are first analyzed using a capillary column to determine the concentration of each isomer of PCDDs and PCDFs (tetra- through octa-). If 2,3,7,8-TCDF is detected in this analysis, another aliquot of the sample is analyzed separately, using a second, dissimilar column to confirm and more accurately measure the 2,3,7,8-TCDF isomer. Other column systems may be used, provided that the user is able to demonstrate by means of calibration and performance checks that the column system is able to meet the specifications of Method 8290.

7.3.8 All other analytical specifications for determining the amounts of PCDD/PCDF isomers collected in the filter/front half and sorbent trap/back half fractions can be found in Method 8290.

7.4 Calculations

The mass of each isomer from the front half train fraction is added to that from the back half fraction to obtain a train total before further calculation. If a measurable amount of the isomer is found in one fraction, but the amount in the second fraction is below detection limit, the following strategy is recommended, but is subject to being overruled by regulatory authorities. Count the "nondetect" as zero if the detection limit is less than 10% of the total of the detected amount from the other fraction. In cases where the detection limit in the second fraction is greater than 10% of

the amount detected in the first fraction, then report the total as greater than the detected amount but less than the detected amount plus the second fraction detection limit.

The following section describes the calculations used to determine gas concentrations and emissions of PCDD and PCDF isomers. Toxic equivalent calculations are not included in this method. Each set of calculations should be repeated or spot-checked, as a QC measure. Calculations should be carried out to at least one extra decimal place beyond that of the acquired data and should be rounded off after final calculation to two significant digits for each run or sample. All rounding of numbers should be performed in accordance with the ASTM 380-76 procedures.

The nomenclature and sampling equations are presented in Sec. 7.4.1.

7.4.1 Sampling nomenclature

A_n = Cross sectional area of nozzle, m^2 (ft^2).

A_s = Cross sectional area of stack, m^2 (ft^2).

B_{ws} = Water vapor in the gas stream, proportion by volume.

C_i = Concentration of pollutant i, µg/dscm (lb/dscf).

E_i = Emission rate of pollutant i, g/sec (lb/hr).

D_N = Diameter of nozzle, mm (in.)

I = Percent of isokinetic sampling.

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).

M_d = Molecular weight of dry stack gas, g/g-mole (lb/lb-mole).

M_s = Molecular weight of wet stack gas, g/g-mole (lb/lb-mole).

m_i = Mass of pollutant i collected by sampling train, µg (lb).

P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg).

P_{static} = Static gauge pressure of stack gas, mm H_2O (in. H_2O).

P_s = Absolute stack gas pressure, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

Q_{sd} = Average stack gas volumetric flow, dry, standard conditions, dscmm (dscfm).

R = Ideal gas constant, 0.06236 [(mm Hg) (m^3)] / [(°K) (g-mole)] {21.85 [(in. Hg) (ft^3)] / [(°R) (lb-mole)]}.

T_m = Absolute average DGM temperature°K (°R).

T_s = Absolute average stack gas temperature °K (°R).

T_{std} = Standard absolute temperature, 293°K (528°R).

V_{lc} = Total volume liquid collected in impingers and silica gel (mL).

V_m = Volume of gas sample as measured by dry gas meter, dcm (dcf).

$V_{m(std)}$ = Volume of gas sample measured by the dry gas meter, corrected to standard conditions, dscm (dscf).

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).

V_s = Stack gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 5, m/sec (ft/sec).

Y = Dry gas meter calibration factor.

ΔP = Average pressure differential across pitot tube, mm H_2O (in.H_2O).

ΔH = Average pressure differential across the orifice meter, mm H_2O (in. H_2O).

ρ_w = Density of water, 0.9982 g/mL (0.002201 lb/mL).

θ = Total sampling time, min.

K_p = $$85.49 \frac{ft}{sec}\left[\frac{(lb/lb-mole)\ (in.\ Hg)}{°R\ (in.\ H_20)}\right]^{1/2}$$

13.6 = Specific gravity of mercury.

7.4.2 Dry gas volume - Correct the sample volume measured by the dry gas meter to standard conditions (20°C, 760 mm Hg or 68°F, 29.92 in. Hg) by using the following equation, where:

K_i = 0.3858 °K/mm Hg for metric units, or

= 17.64 °F/in. Hg for English units.

If the leak corrections to sample volume are necessary and have been approved by the test administrator, follow procedures listed in Method 0010.

7.4.3 Volume of water vapor

$$V_{w(std)} = V_{lc}\frac{\rho_w\ R\ T_{std}}{M_w\ P_{std}} = K_2\ V_{lc}$$

where:

$$K_2 = 0.001333 \text{ m}^3/\text{mL for metric units, or}$$

$$= 0.04707 \text{ ft}^3/\text{mL for English units.}$$

7.4.4 Moisture content

$$B_{ws} = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}}$$

NOTE: In saturated or water droplet-laden gas streams, two calculations of the moisture content of the stack gas should be made, one from the impinger analysis (Sec. 7.4.3), and a second from the assumption of saturated conditions. The lower of the two values of B_{ws} should be considered correct. The procedure for determining the moisture content based upon assumption of saturated conditions is given in a "Note" in Sec. 1 of Method 4. For the purposes of this method, the average stack gas temperature may be used to make this determination, provided that the accuracy of the in-stack temperature sensor is ± 2°C.

7.4.5 Absolute stack gas pressure

$$P_s = P_{bar} + \frac{P_{static}}{13.6}$$

7.4.6 Average molecular weight of dry stack gas

$$\text{Dry: } M_d = (0.32 \times \%O_2) \times (0.44 \times \%CO_2) + (0.28 \times (100 - (\%O_2 + \%CO_2))$$

$$\text{Wet: } M_s = M_d \times (1 - B_{ws}) + (B_{ws} \times M_w)$$

7.4.7 Stack gas velocity at stack conditions

$$V_s = K_p \times C_p \times \sqrt{\Delta P} \times \sqrt{\frac{T_s + T_{std}}{P_s \times M_s}}$$

7.4.8 Average stack gas volumetric flow at dry, standard conditions

$$Q_{sd} = V_s \times A_s \times (1 - B_{ws}) \times \frac{T_{std} \times P_s}{T_s \times P_{std}} \times \frac{60 \text{ sec}}{\text{min}}$$

7.4.9 Concentration of pollutant

$$C_i = \frac{M_i}{V_{m(std)}}$$

7.4.10 Emission of pollutant

$$E_i = \frac{C_i \times Q_{sd}}{\left(60 \ \frac{sec}{min}\right)\left(1 \times 10^6 \ \frac{ug}{g}\right)}$$

7.4.11 Isokinetic sampling rate

$$\%I = \frac{1039.5746 \times V_{m(std)} \times (T_s + 460)}{V_s \times \theta \times P_s \times (1 - B_{ws}) \times (D_n)^2}$$

*English units

8.0 QUALITY CONTROL

The following quality control (QC) guidelines outline pertinent steps to be followed during the production of emission data to ensure and quantify the acceptability and reliability of the data generated.

8.1 Sampling QC procedures - Quality control procedures specific to manual source gas sampling procedures should follow EPA Method 5 and those listed in EPA Manual 600/4-77-0276 for Method 5. Sampling QC procedures are summarized in Table 2.

8.2 Blanks

8.2.1 Field blank - A field blank should be collected from a set of glassware that has not been used to collect any field samples. In the case of results exceeding regulatory limits, field blank data may be useful for convincing the regulatory official that contamination was the cause. This may result in retesting rather than a violation charge. Collection of the field blank is optional but recommended. Collect one field blank for every nine test runs at each test location.

8.2.2 Optional Glassware blank (proof blank) - A proof blank should be periodically recovered from sampling train glassware that is used to collect organic samples. The precleaned glassware, which consists of a probe liner, filter holder, condenser coil, and impinger set, is loaded as if for sampling and then quantitatively recovered exactly as the samples will be. Analysis of the generated fractions will ensure that laboratory contamination levels are under control.

8.2.3 Reagent blank - Reagent blanks should contain 500 mL of each reagent used at the test site. Reagent blanks are saved for potential analysis. Each reagent blank is part of the same lot used during the sampling program. If a field blank is unsatisfactory because of contamination, reagent blanks may be analyzed to determine the specific source of contamination. Collect one reagent blank per compliance test and archive for future analysis in the event that the field blank shows contamination.

8.2.4 Laboratory method blank - A method blank is a performance control sample that is prepared in the laboratory and processed in a manner identical to a field sample. The XAD-2® resin should be from the same batch used for preparation of the field traps. One laboratory method blank should be analyzed for every batch of samples analyzed.

9.0 METHOD PERFORMANCE

9.1 Method performance evaluation - Evaluation of analytical procedures for a selected series of compounds shall include the sample preparation procedures and each associated analytical determination. The analytical procedures should be challenged by the test compounds spiked at appropriate levels and carried through the procedures.

9.2 Method detection limit - The overall method detection limits (lower and upper) should be calculated as shown in Sec. 6.2.3.1. Generally, analytical detection limit for tetra-CDD/CDF congeners are 50 pg. Penta-, hexa-, and hepta- congener detection limits are 250 pg and octa-congener detection limits are 500 pg.

9.3 Method precision and bias - The overall method precision and bias should be determined on a compound-by-compound basis at a given concentration level. The method precision value includes a combined variability due to sampling, sample preparation, and instrumental analysis. The method bias is dependent upon the collection, retention, and extraction efficiency of the train components. Interlaboratory testing of Method 0023 and Method 8290 to establish method accuracy and precision for sampling a variety of stationary sources has not been performed.

TABLE 2

SAMPLING QC PROCEDURES SUMMARY

QC Procedure	Frequency	Criteria
Sample equipment calibrations	See Sec. 6.3.1	See Sec. 6.3.1
Dry gas meter sample leak check	Before and after each test run	0.00057 cmm ($\leq$ 0.02 cfm) or 4% of sample rate whichever is less at highest vacuum
O_2 and CO_2 sampling system leak check	Once per test	See Method 3, or equivalent for Method 3A
ΔP meter leveling	Before and after each test run	Level
Pitot tube leak check	Before and after each test run	No visible leak observed at 75 mm (3 in.) H_2O for 15 seconds
Pitot tube orientation check	Every test	Pitot tube is level with no visible rotation from perpendicular to flow
Cyclonic flow check	Made at every location	$< 20^\circ$ average offset from perpendicular to flow
Probe, filter, trap, and silica gel impinger are maintained at specified temperature ranges	Every test	See Sec. 4.0
Overall isokinetic sampling rate	Every test	± 10% of 100%
Sampling blanks	See Sec. 8.2	See Sec. 8.2

TABLE 3

REQUIREMENTS FOR ANALYTICAL PREPARATION,
SURROGATE RECOVERIES AND SAMPLE BLANKS

Item	Description	Control Limit
Precleaning filters	Soxhlet extraction	Detection limits listed in Sec. 9.2
Precleaning sorbent	Soxhlet extraction	Detection limits listed in Sec. 9.2
Filter and sorbent surrogate spikes	Isotopically-labeled compounds	70 to 130% recovery
Field blank	Collect one for every 9 sample runs at each test location	< 5 times the detection limits
Method blank	Prepared at analytical laboratory (laboratory blank). One per analytical batch	Criteria decided by laboratory QA officer
Reagent blanks	One per lot of solvent used. Archive for possible analysis	Analyze only if requested by Agency to determine source of field blank confirmation
Proof Blank	One per set of glassware. Archive for possible analysis (collect only if requested by Agency)	Analyze only if requested by Agency to determine source of field blank contamination

APPENDIX A
RECOMMENDED AUDITING PROCEDURES

An audit is an independent assessment of data quality. Both performance audits and system audits may be performed.

Performance Audit - A performance audit is conducted to evaluate quantitatively the quality of data produced by the sampling, analysis, or the total measurement system (sample collection, sample recovery, sample analysis, and data processing).

Audit Sample - A performance audit sample contains tetra- through octa-isomers of PCDD and PCDF. Audit samples are not normally required.

Performance Audit of the Field Test - A field test performance audit may be conducted by checking the dry gas meter for accuracy using procedures located in the Quality Assurance Handbook for Air Pollution Measurement Systems (EPA 600/4-77-027b). Performance audits on thermocouple readings, ΔP gauges, barometric pressure gauges and others, may also be conducted.

Performance Audit of Data Processing - The data processing procedures may be audited by requiring the testing laboratory to provide an example calculation for one sample run. This example calculation will include all the calculations used to determine the emissions based on the raw field and laboratory data.

System Audit - A system audit is an on-site, qualitative inspection and review of the total measurement system.

The functions of the auditor are:

a) Observe procedures and techniques of the field team during sample collection and sample recovery; and

b) Examine records of apparatus calibrations and other quality control procedures used in sampling and analytical activities

When on-site, the auditor observes the source test team's overall performance, including the following operations:

a) Setting the sampling system and leak checking the sample train and pitot tube;

b) Collecting the samples isokinetically;

c) Conducting the final leak checks; and

d) Sample documentation procedures, sample recovery, and preparation of the samples for shipment.

METHOD 0030

VOLATILE ORGANIC SAMPLING TRAIN

1.0 PRINCIPLE AND APPLICATION

1.1 Principle

1.1.1 This method describes the collection of volatile principal organic hazardous constituents (POHCs) from the stack gas effluents of hazardous waste incinerators. For the purpose of definition, volatile POHCs are those POHCs with boiling points less than 100°C. If the boiling point of a POHC of interest is less than 30°C, the POHC may break through the sorbent under the conditions of the sample collection procedure.

1.1.2 Field application for POHCs of this type should be supported by laboratory data which demonstrate the efficiency of a volatile organic sampling train (VOST) to collect POHCs with boiling points less than 30°C. This may require using reduced sample volumes collected at flow rates between 250 and 500 mL/min. Many compounds which boil above 100°C (e.g., chlorobenzene) may also be efficiently collected and analyzed using this method. VOST collection efficiency for these compounds should be demonstrated, where necessary, by laboratory data of the type described above.

1.1.3 This method employs a 20-liter sample of effluent gas containing volatile POHCs which is withdrawn from a gaseous effluent source at a flow rate of 1 L/min, using a glass-lined probe and a volatile organic sampling train (VOST). (Operation of the VOST under these conditions has been called FAST-VOST.) The gas stream is cooled to 20°C by passage through a water-cooled condenser and volatile POHCs are collected on a pair of sorbent resin traps. Liquid condensate is collected in an impinger placed between the two resin traps. The first resin trap (front trap) contains approximately 1.6 g Tenax and the second trap (back trap) contains approximately 1 g each of Tenax and petroleum-based charcoal (SKC Lot 104 or equivalent), 3:1 by volume. A total of six pairs of sorbent traps may be used to collect volatile POHCs from the effluent gas stream.

1.1.4 An alternative set of conditions for sample collection has been used. This method involves collecting sample volume of 20 liters or less at reduced flow rate. (Operation of the VOST under these conditions has been referred to as SLO-VOST.) This method has been used to collect 5 liters of sample (0.25 L/min for 20 min) or 20 liters of sample (0.5 L/min for 40 min) on each pair of sorbent cartridges. Smaller sample volumes collected at lower flow rates should be considered when the boiling points of the POHCs of interest are below 35°C. A total of six pairs of sorbent traps may be used to collect volatile POHCs from the effluent gas stream.

1.1.5 Analysis of the traps is carried out by thermal desorption purge-and-trap by gas chromatography/mass spectrometry (see Method 5040). The VOST is designed to be operated at 1 L/min with traps being replaced every 20 min for a total sampling time of 2 hr. Traps may be analyzed separately or combined onto one trap to improve detection limit. However, additional flow rates and sampling times are acceptable. Recent experience has shown that when less than maximum detection ability is required, it is acceptable and probably preferable to operate the VOST at 0.5 L/min for a total of three 40-min periods. This preserves the 2-hr sampling period, but reduces the number of cartridge changes in the field as well as the number of analyses required.

1.2 Application

1.2.1 This method is applicable to the determination of volatile POHCs in the stack gas effluent of hazardous waste incinerators. This method is designed for use in calculating destruction and removal efficiency (DRE) for the volatile POHCs and to enable a determination that DRE values for removal of the volatile POHCs are equal to or greater than 99.99%.

1.2.2 The sensitivity of this method is dependent upon the level of interferences in the sample and the presence of detectable levels of volatile POHCs in blanks. The target detection limit of this method is 0.1 ug/m^3 (ng/L) of flue gas, to permit calculation of a DRE equal to or greater than 99.99% for volatile POHCs which may be present in the waste stream at 100 ppm. The upper end of the range of applicability of this method is limited by breakthrough of the volatile POHCs on the sorbent traps used to collect the sample. Laboratory development data have demonstrated a range of 0.1 to 100 ug/m^3 (ng/L) for selected volatile POHCs collected on a pair of sorbent traps using a total sample volume of 20 liters or less (see Paragraph 1.1.4).

1.2.3 This method is recommended for use only by experienced sampling personnel and analytical chemists or under close supervision by such qualified persons.

1.2.4 Interferences arise primarily from background contamination of sorbent traps prior to or after use in sample collection. Many potential interferences can be due to exposure of the sorbent materials to solvent vapors prior to assembly and exposure to significant concentrations of volatile POHCs in the ambient air at hazardous waste incinerator sites.

1.2.5 To avoid or minimize the low-level contamination of train components with volatile POHCs, care should be taken to avoid contact of all interior surface or train components with synthetic organic materials (e.g., organic solvents, lubricating and sealing greases), and train components should be carefully cleaned and conditioned according to the procedures described in this protocol.

2.0 APPARATUS

2.1 Volatile Organic Sampling Train: A schematic diagram of the principal components of the VOST is shown in Figure 1 and a diagram of one acceptable version of the VOST is shown in Figure 2. The VOST consists of a glass-lined probe followed by an isolation valve, a water-cooled glass condenser, a sorbent cartridge containing Tenax (1.6 g), an empty impinger for condensate removal, a second water-cooled glass condenser, a second sorbent cartridge containing Tenax and petroleum-based charcoal (3:1 by volume; approximately 1 g of each), a silica gel drying tube, a calibrated rotameter, a sampling pump, and a dry gas meter. The gas pressure during sampling and for leak-checking is monitored by pressure gauges which are in line and downstream of the silica gel drying tube. The components of the sampling train are described below.

2.1.1 **Probe:** The probe should be made of stainless steel with a borosilicate or quartz glass liner. The temperature of the probe is to be maintained above 130°C but low enough to ensure a resin temperature of 20°C. A water-cooled probe may be required at elevated stack temperatures to protect the probe and meet the above requirements. Isokinetic sample collection is not a requirement for the use of VOST since the compounds of interest are in the vapor phase at the point of sample collection.

2.1.2 **Isolation valve:** The isolation valve should be a greaseless stopcock with a glass bore and sliding Teflon plug with Teflon wipers (Ace 8193 or equivalent).

2.1.3 **Condensers:** The condensers (Ace 5979-14 or equivalent) should be of sufficient capacity to cool the gas stream to 20°C or less prior to passage through the first sorbent cartridge. The top connection of the condenser should be able to form a leak-free, vacuum-tight seal without using sealing greases.

2.1.4 **Sorbent cartridges:**

2.1.4.1 The sorbent cartridges used for the VOST may be used in either of two configurations: the inside-outside (I/O) configuration in which the cartridge is held within an outer glass tube and in a metal carrier, and the inside-inside (I/I) configuration in which only a single glass tube is used, with or without a metal carrier. In either case, the sorbent packing will be the same.

2.1.4.1.1 The first of a pair of sorbent cartridges shall be packed with approximately 1.6 g Tenax GC resin and the second cartridge of a pair shall be packed with Tenax GC and petroleum-based charcoal (3:1 by volume; approximately 1 g of each).

2.1.4.1.2 The second sorbent cartridge shall be packed so that the sample gas stream passes through the Tenax layer first and then through the charcoal layer.

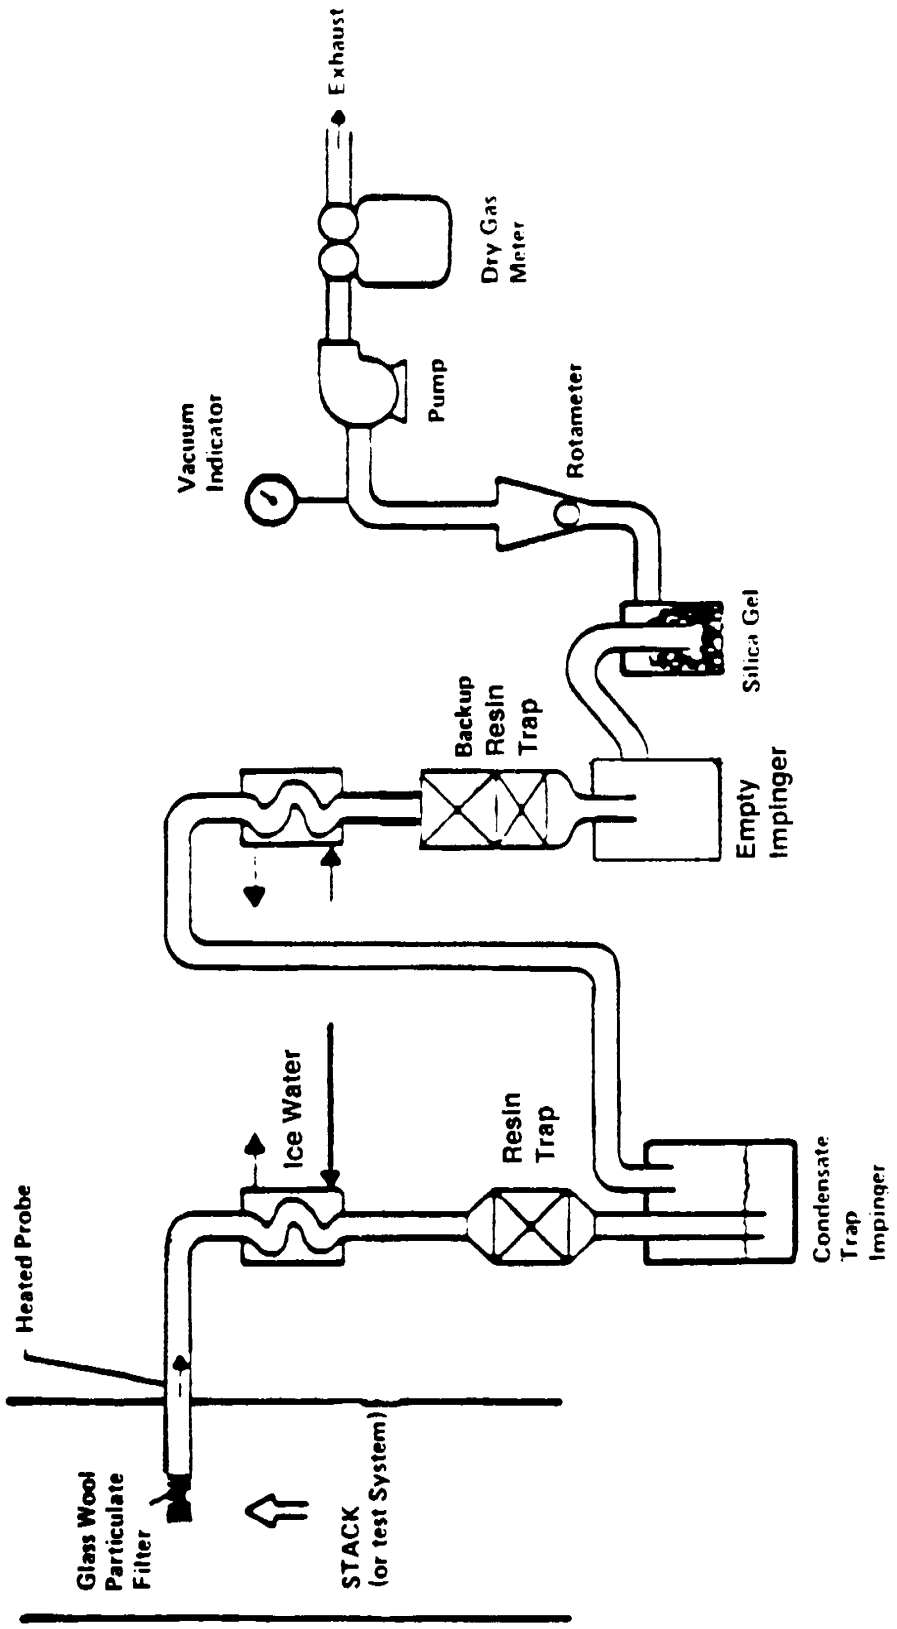

Figure 1. Schematic of Volatile Organic Sampling Train (VOST).

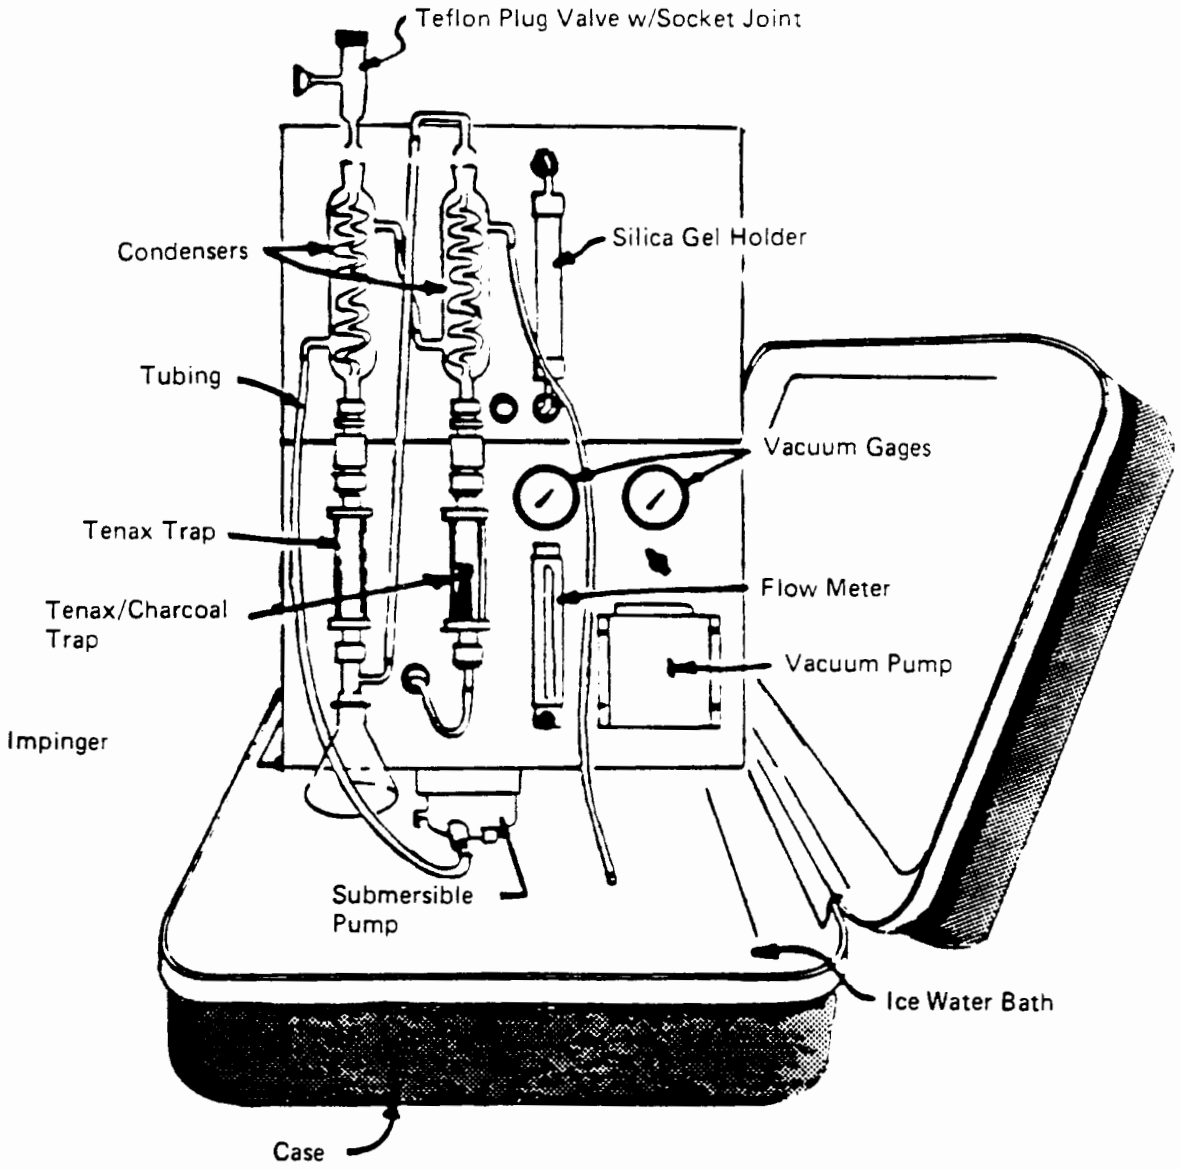

Figure 2. Volatile Organic Sampling Train (VOST).

2.1.4.2 The sorbent cartridges shall be glass tubes with approximate dimensions of 10 cm by 1.6 cm I.D. The two acceptable designs (I/O, I/I) for the sorbent cartridge are described in further detail below.

2.1.4.2.1 **Inside/Inside sorbent cartridge:** A diagram of an I/I sorbent cartridge is shown in Figure 3. This cartridge is a single glass tube (10 cm by 1.6 cm I.D.) which has the ends reduced in size to accommodate a 1/4- or 3/8-in. Swagelok or Cajon gas fitting. The resin is held in place by glass wool at each end of the resin layer. The amounts of each type of sorbent material used in the I/I design are the same as for the I/O design. Threaded end caps are placed on the sorbent cartridge after packing with sorbent to protect the sorbent from contamination during storage and transport.

2.1.4.2.2 **Inside/Outside type sorbent cartridge:** A diagram of an I/O sorbent cartridge is shown in Figure 4. In this design the sorbent materials are held in the glass tube with a fine mesh stainless steel screen and a C-clip. The glass tube is then placed within a larger diameter glass tube and held in place using Viton O-rings. The purpose of the outer glass tube is to protect the exterior of the resin-containing tube from contamination. The two glass tubes are held in a stainless steel cartridge holder, where the ends of the glass tubes are held in place by Viton O-rings placed in machine grooves in each metal end piece. The three cylindrical rods are secured in one of the metal end pieces and fastened to the other end piece using knurled nuts, thus sealing the glass tubes into the cartridge holder. The end pieces are fitted with a threaded nut onto which a threaded end cap is fitted with a Viton O-ring seal, to protect the resin from contamination during transport and storage.

2.1.5 **Metering system:** The metering system for VOST shall consist of vacuum gauges, a leak-free pump (Thomas Model 107 or equivalent, Thomas Industries, Sheboygan, Wisconsin), a calibrated rotameter (Linde Model 150, Linde Division of Union Carbide, Keasbey, New Jersey) for monitoring the gas flow rate, a dry gas meter with 2% accuracy at the required sampling rate, and related valves and equipment. Provisions should be made for monitoring the temperature of the sample gas stream between the first condenser and first sorbent cartridge. This can be done by placing a thermocouple on the exterior glass surface of the outlet from the first condenser. The temperature at that point should be less than 20°C. If it is not, an alternative condenser providing the required cooling capacity must be used.

2.1.6 **Sample transfer lines:** All sample transfer lines to connect the probe to the VOST shall be less than 5 ft in length, and shall be heat-traced Teflon with connecting fittings which are capable of forming leak-free, vacuum-tight connections without the use of sealing grease.

All other sample transfer lines used with the VOST shall be Teflon with connecting fittings that are capable of forming leak-free, vacuum-tight connections without the use of sealing grease.

3.0 REAGENTS AND MATERIALS

3.1 2,6-Diphenylene oxide polymer (Tenax, 35/60 mesh):

3.1.1 The new Tenax is Soxhlet extracted for 24 hr with methanol (Burdick & Jackson, pesticide grade or equivalent). The Tenax is dried for 6 hr in a vacuum oven at 50°C before use. Users of I/O and I/I sorbent cartridges have used slightly different thermal conditioning procedures. I/O sorbent cartridges packed with Tenax are thermally conditioned by flowing organic-free nitrogen (30 mL/min) through the resin while heating to 190°C. Some users have extracted new Tenax and charcoal with pentane to remove nonpolar impurities. However, these users have experienced problems with residual pentane in the sorbents during analysis.

3.1.2 If very high concentrations of volatile POHCs have been collected on the resin (e.g., micrograms of analytes), the sorbent may require Soxhlet extraction as described above. Previously used Tenax cartridges are thermally reconditioned by the method described above.

3.2 Charcoal (SKC petroleum-base or equivalent): New charcoal is prepared and charcoal is reconditioned as described in Paragraph 4.4. New charcoal does not require treatment prior to assembly into sorbent cartridges. Users of VOST have restricted the types of charcoal used in sorbent cartridges to only petroleum-based types. Criteria for other types of charcoal are acceptable if recovery of POHC in laboratory evaluations meet the criteria of 50 to 150%.

3.3 Viton-O-Ring: All O-rings used in VOST shall be Viton. Prior to use, these O-rings should be thermally conditioned at 200°C for 48 hr.
O-rings should be stored in clean, screw-capped glass containers prior to use.

3.4 Glass tubes/Condensers: The glass resin tubes and condensers should be cleaned with a nonionic detergent in an ultrasonic bath, rinsed well with organic-free water, and dried at 110°C. Resin tubes of the I/O design should be assembled prior to storage as described in Paragraph 4.1. Resin tubes of the I/I design can be stored in glass culture tube containers with cotton cushioning and Teflon-lined screw caps. Condensers can be capped with appropriate end caps prior to use.

3.5 Metal parts: The stainless steel carriers, C-clips, end plugs, and screens used in the I/O VOST design are cleaned by ultrasonication in a warm nonionic detergent solution, rinsed with distilled water, air-dried, and heated in a muffle furnace for 2 hr at 400°C. Resin tubes of the I/I design require Swagelok or equivalent end caps with Supelco M-1 ferrules. These should be heated at 190°C along with the assembled cartridges.

3.6 Silica gel (Indicating type, 6-16 mesh): New silica gel may be used as received. Silica gel which has been previously used should be dried for 2 hr at 175°C (350°F).

3.7 Cold packs: Any commercially available reusable liquids or gels that can be repeatedly frozen are acceptable. They are typically sold in plastic containers as "Blue Ice" or "Ice-Packs." Enough should be used to keep cartridges at or near 4°C.

3.8 Water: Water used for cooling train components in the field may be tap water; and water used for rinsing glassware should be organic-free.

3.9 Glass wool: Glass wool should be Soxhlet extracted for 8 to 16 hr, using methanol, and oven dried at 110°C before use.

4.0 SAMPLE HANDLING AND PROCEDURE

4.1 Assembly:

4.1.1 The assembly and packing of the sorbent cartridges should be carried out in an area free of volatile organic material, preferably a laboratory in which no organic solvents are handled or stored and in which the laboratory air is charcoal filtered. Alternatively, the assembly procedures can be conducted in a glove box which can be purged with organic-free nitrogen.

4.2 Tenax cartridges:

4.2.1 The Tenax, glass tubes, and metal cartridge parts are cleaned and stored (see Section 3.0). Approximately 1.6 g of Tenax is weighed and packed into the sorbent tube which has a stainless steel screen and C-clip (I/O design) or glass wool (I/I design) in the downstream end. The Tenax is held in place by inserting a stainless steel screen and C-clips in the upstream end (I/O design) or glass wool (I/I design). Each cartridge should be marked, using an engraving tool, with an arrow to indicate the direction of sample flow, and a serial number.

4.2.2 Conditioned resin tubes of the I/O design are then assembled into the metal carriers according to the previously described inside/inside or inside/outside procedures (with end caps) and are placed on cold packs for storage and transport. Conditioned resin tubes of the I/I design are capped and placed on cold packs for storage and transport.

4.3 Tenax/Charcoal tubes

4.3.1 The Tenax, charcoal, and metal cartridge parts are cleaned and stored as previously described (see Section 3.0). The tubes are packed with approximately a 3:1 volume ratio of Tenax and charcoal (approximately 1 g each). The Tenax and charcoal are held in place by the stainless steel screens and C-clips (I/O design) or by glass wool (I/I design). The glass tubes containing the Tenax and charcoal are then

conditioned as described below (see Paragraph 4.4). Place the I/O glass tubes in the metal carriers (see Paragraph 2.1.4.2.2), put end caps on the assembled cartridges, mark direction of sample flow and serial number, and place the assembled cartridges on cold packs for storage and transport.

4.3.2 Glass tubes of the I/I design are conditioned, and stored in the same manner as the I/O tubes.

4.4 Trap Conditioning - QC

4.4.1 Following assembly and leak-checking, the traps are connected in reverse direction to sampling to a source of organic-free nitrogen, and nitrogen is passed through each trap at a flow rate of 40 mL/min, while the traps are heated to 190°C for 12-28 hr. The actual conditioning period may be determined based on adequacy of the resulting blank checks.

4.4.2 The following procedure is used to blank check each set of sampling cartridges prior to sampling to ensure cleanliness. The procedure provides semi-quantitative data for organic compounds with boiling points below 110°C on Tenax and Tenax/Charcoal cartridges. It is not intended as a substitute for Method 5040.

4.4.2.1 The procedure is based on thermal desorption of each set of two cartridges, cryofocusing with liquid nitrogen onto a trap packed with glass beads, followed by thermal desorption from the trap and analysis by GC/FID.

4.4.2.2 The detection limit is based on the analysis of Tenax cartridges spiked with benzene and toluene and is around 2 ng for each compound.

4.4.2.3 The results of analyzing spiked cartridges on a daily basis should not vary by more than 20 percent. If the results are outside this range, the analytical system must be evaluated for the probable cause and a second spiked cartridge analyzed.

4.4.2.4 The GC operating conditions are as follows:

GC Operating Conditions

Column: Packed column 6 ft x 1/8" stainless steel 1.0 percent SP-1000 on Carbopack B 60/80, or equivalent.
Temperature program: 50°C for 5 min, 20°C/min increase to 190°C, hold 13 min.
Injector: 200°C.
Detector: F.I.D. 250°C.
Carrier Gas: Helium at 25 mL/min.
Sample valve: Valco 6-port with 40" x 1/16" stainless steel trap packed with 60/80 mesh glass beads.
Cryogen: Liquid nitrogen.
Trap heater: Boiling water, hot oil, or electrically heated.

Desorption heater: Supelco "clam shell" (high capacity carrier gas purifier) heater and Variac, adjusted to 180°C to 200°C.

4.4.2.5 Calibration is accomplished by preparing a spiked Tenax cartridge with benzene and toluene and analyzing according to the standard operating procedure. A standard of benzene, toluene and bromofluorobenzene (BFB) is prepared by injecting 2.0 uL of benzene and toluene and 1.0 uL of BFB into 10 mL of methanol. The concentration of this stock is 175 ng/uL of benzene and toluene, and 150 ng/uL BFB. One microliter of the stock standard is injected onto a Tenax cartridge through a heated injection port set at 150°C. A GC oven can be used for this with the oven at room temperature. Helium carrier gas is set at 50 mL/min. The solvent flush technique should be used. After two min, remove the Tenax cartridge and place in the desorption heater for analysis. BFB is also used as an internal standard spike for GC/MS analysis which provides a good comparison between GC/FID and GC/MS. The results of this spike analysis should not vary more than 20 percent day to day. Initially and then periodically this spiked Tenax should be reanalyzed a second time to verify that the 10 min desorption time and 180-200°C temperature are adequate to remove all of the spiked components. It should be noted that only one spiked Tenax cartridge need be prepared and analyzed daily unless otherwise needed to ensure proper instrument operation.

An acceptable blank level is left to the discretion of the method analyst. An acceptable level is one that allows adequate determination of expected components emitted from the waste being burned.

4.4.3 After conditioning, traps are sealed and placed on cold packs until sampling is accomplished. Conditioned traps should be held for a minimum amount of time to prevent the possibility of contamination.

4.4.4 It may be useful to spike the Tenax and Tenax/charcoal traps with the compounds of interest to ensure that they can be thermally desorbed under laboratory conditions. After spiked traps are analyzed they may be reconditioned and packed for sampling.

4.5 Pretest preparation:

4.5.1 All train components shall be cleaned and assembled as previously described. A dry gas meter shall have been calibrated within 30 days prior to use, using an EPA-supplied standard orifice.

4.5.2 The VOST is assembled according to the schematic diagram in Figure 1. The cartridges should be positioned so that sample flow is

through the Tenax first and then the Tenax/charcoal. Cooling water should be circulated to the condensers and the temperature of the cooling water should be maintained near 0°C. The end caps of the sorbent cartridges should be placed in a clean screw-capped glass container during sample collection.

4.6 Leak-checking:

4.6.1 The train is leak-checked by closing the valve at the inlet to the first condenser and pulling a vacuum of 250 mm (10 in. Hg) above the normal operating pressure. The traps and condensers are isolated from the pump and the leak rate noted. The leak rate should be less than 2.5 mm Hg after 1 min. The train is then returned to atmospheric pressure by attaching a charcoal-filled tube to the train inlet and admitting ambient air filtered through the charcoal. This procedure will minimize contamination of the VOST components by excessive exposure to the fugitive emissions at hazardous waste incinerator sites.

4.7 Sample Collection

4.7.1 After leak-checking, sample collection is accomplished by opening the valve at the inlet to the first condenser, turning on the pump, and sampling at a rate of 1 liter/min for 20 min. The volume of sample for any pair of traps should not exceed 20 liters.

4.7.2 Following collection of 20 liters of sample, the train is leak-checked a second time at the highest pressure drop encountered during the run to minimize the chance of vacuum desorption of organics from the Tenax. The train is returned to atmospheric pressure, using the method discussed in Paragraph 4.1 and the two sorbent cartridges are removed. The end caps are replaced and the cartridges shall be placed in a suitable environment for storage and transport until analysis. The sample is considered invalid if the leak test does not meet specification.

4.7.3 A new pair of cartridges is placed in the VOST, the VOST leak-checked, and the sample collection process repeated as described above. Sample collection continues until six pairs of traps have been used.

4.7.4 All sample cartridges should be kept on cold packs until they are ready for analysis.

4.8 Blanks

4.8.1 **Field blanks/trip blanks:** Blank Tenax and Tenax/charcoal cartridges are taken to the sampling site and the end caps removed for the period of time required to exchange two pairs of traps on VOST. After the two VOST traps have been exchanged, the end caps are replaced on the blank Tenax and Tenax/charcoal tubes and these are returned to the cold packs and analyzed with the sample traps. At least one pair of field blanks (one Tenax, one Tenax/charcoal) shall be included with each

six pairs of sample cartridges collected (or for each field trial using VOST to collect volatile POHCs).

4.8.2 **Trip blanks:** At least one pair of blank cartridges (one Tenax, one Tenax/charcoal) shall be included with shipment of cartridges to a hazardous waste incinerator site. These "field blanks" will be treated like any other cartridges except that the end caps will not be removed during storage at the site. This pair of traps will be analyzed to monitor potential contamination which may occur during storage and shipment.

4.8.3 **Laboratory blanks:** One pair of blank cartridges (one Tenax, one Tenax/charcoal) will remain in the laboratory using the method of storage which is used for field samples. If the field and trip blanks contain high concentrations of contaminants (e.g., greater than 2 ng of a particular POHC), the laboratory blank shall be analyzed in order to identify the source of contamination.

5.0 CALCULATIONS (for sample volume)

5.1 The following nomenclature are used in the calculation of sample volume:

P_{bar} = Barometric pressure at the exit orifice of the dry gas meter, mm (in.) Hg.

P_{std} = Standard absolute pressure, 760 mm (29.92 in.) Hg.

T_m = Dry gas meter average absolute temperature, K (°R).

T_{std} = Standard absolute temperature, 293K (528°R).

V_m = Dry gas volume measured by dry gas meter, dcm (dcf).

$V_{m(std)}$ = Dry gas volume measured by dry gas meter, corrected to standard conditions, dscm (dscf).

γ = Dry gas meter calibration factor.

5.2 The volume of gas sampled is calculated as follows:

$$V_{m(std)} = V_m \gamma \frac{T_{std}\ P_{bar}}{T_m\ P_{std}} = K_1 \gamma \frac{V_m\ P_{bar}}{T_m}$$

where:

K_1 = 0.3858 K/mm Hg for metric units, or

K_1 = 17.64 °R/in. Hg for English units.

6.0 ANALYTICAL PROCEDURE

See Method 5040.

7.0 PRECISION AND ACCURACY REQUIREMENTS

7.1 Method Performance Check

Prior to field operation of the VOST at a hazardous waste incinerator, a method performance check should be conducted using either selected volatile POHCs of interest or two or more of the volatile POHCs for which data are available. This check may be conducted on the entire system (VOST/GC/MS) by analysis of a gas cylinder containing POHCs of interest or on only the analytical system by spiking of the POHCs onto the traps. The results of this check for replicate pairs of traps should demonstrate that recovery of the analytes fall within 50% to 150% of the expected values.

7.2 Performance Audit

During a trial burn a performance audit must be completed. The audit results should agree within 50% to 150% of the expected value for each specific target compound. This audit consists of collecting a gas sample containing one or more POHCs in the VOST from an EPA ppb gas cylinder. Collection of the audit sample in the VOST may be conducted either in the laboratory or at the trial burn site. Anaysis of the VOST audit sample must be by the same person, at the same time, and with the same analytical procedure as used for the regular VOST trail burn samples. EPA ppb gas cylinders currently available for VOST Audit are shown in Table 1 below.

The audit procedure, audit equipment and audit cylinder may be obtained by writing:

Audit Cylinder Gas Coordinator (MD-77B)
Quality Assurance Division
Environmental Monitoring Systems Laboratory
U.S. Environmental Protection Agency
Research Triangle Park, NC 27711

or by calling the Audit Cylinder Gas Coordinator at (919) 541-4531.

The request for the audit must be made at least 30 days prior to the scheduled trial burn. If a POHC is selected for which EPA does not have an audit cylinder, this audit is not required.

Methylene chloride	
Propylene oxide	
Ortho-xylene	

SAMPLING METHOD FOR VOLATILE ORGANIC COMPOUNDS (SMVOC)

1.0 SCOPE AND APPLICATION

1.1 Method 0031 is used to determine volatile organic compounds in gaseous emissions from a wide variety of stationary sources including hazardous waste incinerators. The following compounds may be determined by this method:

Compound	Boiling Point (°C)	CAS No.[a]
Acrylonitrile[b]	77	107-13-1
Benzene	80	71-43-2
Bromodichloromethane	87	75-27-4
Carbon disulfide	46	75-15-0
Carbon tetrachloride	77	56-23-5
Chlorodibromomethane	119-120 @ 748 mm Hg	124-48-1
Chloroform	61	67-66-3
Chloroprene[c]	59	126-99-8
Dibromomethane	97	74-95-3
1,1-Dichloroethane	57	75-34-3
1,2-Dichloroethane	83	107-06-2
1,1-Dichloroethene	32	75-35-4
trans-1,2-Dichloroethene	48	156-60-5
1,2-Dichloropropane	96	78-87-5
1,3-Dichloropropene	106 @ 730 mm Hg	542-75-6
Methylene chloride	39	75-09-2
Tetrachloroethene	121	127-18-4
Toluene	111	108-88-3
1,1,1-Trichloroethane	75	71-55-6
1,1,2-Trichloroethane	113	79-00-5
Trichloroethene	87	79-01-6
Trichlorofluoromethane	24	75-69-4

[a] Chemical Abstract Services Registry Number.
[b] The water solubility and reactivity of this compound may cause problems with some stationary sources.
[c] Reactive compound; may interact with the test matrix.

1.2 Method 0031 may be used to prepare volatile organic compounds that have a boiling point between -15°C and 121°C. Field application for volatile organic compounds with boiling points less than 0°C should be supported by data obtained from laboratory gaseous dynamic spiking and gas chromatographic/mass spectrometric (GC/MS) analysis according to Methods 5041 and 8260 to demonstrate the efficiency of the sampling and analysis method.

1.3 The method is not applicable to particulates or aerosols since isokinetic sampling is not performed. Isokinetic sampling is not required because the volatile organic compounds are in the gas phase when they are sampled.

1.4 Application of Method 0031 is not restricted to those compounds in the target analyte list, however, detection limits have been determined for these compounds and acceptable method performance data have been obtained. Method 0031 may also be applied to the compounds listed in Table 1 if extra care is taken because of the high volatility of these compounds.

1.5 Method 0031 is generally not applicable to polar water-soluble and reactive volatile organic compounds. Examples of polar water-soluble and reactive compounds are shown in Table 2. Other examples where Method 0030 (VOST) sampling and analytical methodology has been used inappropriately include: bromoform (boiling point 137°C, above the maximum limit allowed by the methodology), ethylbenzene (136°C), 1,2,3-trichloropropane (156°C), xylenes (~140°C), styrene (146°C), 1,1,2,2-tetrachloroethane (146°C at 746 mm Hg), and the dichlorobenzenes (~175°C). Although successful analysis for these compounds can be demonstrated by spiking sorbent tubes, the compounds will not be collected quantitatively at the upper temperature limit for the operation of the SMVOC train.

1.6 This method is applicable to the determination of volatile organic compounds in the gaseous effluent of stationary sources such as hazardous waste incinerators with an upper concentration limit per compound in the emissions of approximately 1.5 parts per million (ppm). Method 0031 is not appropriate for gaseous volatile organic compound concentrations above this limit, since saturation of the analytical system or compound breakthrough in the field may occur. Modifications of analytical methods to reduce the concentration of compounds entering the gas chromatograph/mass spectrometer (GC/MS), such as splitters or dilutions, may prevent saturation of the analytical system, but the analytical data are not accurate if breakthrough has occurred during sampling. The analysis of screening samples or distributive volume samples is recommended to prevent analytical system saturation when high analyte concentrations may be encountered.

1.7 The sensitivity of this method is dependent upon the level of interferences in the sample matrix and the presence of detectable levels of volatile organic compounds in the blanks. The target detection limit of this method is 0.1 $\mu g/m^3$ (ng/L) of gaseous effluent. The upper end of the range of applicability of this method is limited by breakthrough of the volatile organic compounds on the sorbent traps used to collect the sample and the ability of the analytical system to respond within the linear range of the instrumentation. Laboratory method development data have demonstrated a range of 0.1 to 100 $\mu g/m^3$ (ng/L) for selected volatile organic compounds collected on a set of sorbent traps using a total sample volume of 20 L or less (see Sec. 2.3).

1.8 The SMVOC is designed to be operated at a sampling rate of 1 L/min with traps being replaced every 20 min for a total sampling time of 2 hrs. Analysis of the traps is carried out by thermal desorption purge-and-trap gas chromatography/mass spectrometry (see Methods 5041 and 8260). Traps may be analyzed separately or combined onto one trap to improve detection limits. Additional flow rates and sampling times are acceptable. For example, when less than maximum detection ability is needed, it is acceptable to operate the SMVOC at 0.5 L/min for a total of three 40-minute periods (two-hour total sampling time). In this example, a two-hour sampling time is maintained, but the number of sampling tubes which must be changed in the field is minimized, as is the number of analyses which must be performed.

NOTE: The SMVOC sampling train may be operated no slower than 0.25 L/min, and no faster than 1 L/min.

1.9 This method is restricted to use by, or under close supervision of, trained analytical personnel experienced in sampling volatile organic compounds in air. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 This method employs a sampling module and meter box to withdraw a 20-L sample of effluent gas containing volatile organic compounds from a stationary source at a flow rate of 1 L/min, using a glass-lined probe heated to 130 ± 5°C and a sampling method for volatile organic compounds (SMVOC) train.

2.2 The gas stream is cooled to 20°C by passage through a water-cooled condenser and volatile organic compounds are collected on a set of sorbent traps (Tenax®-GC/Tenax®-GC/Anasorb®-747). Liquid condensate is collected in an impinger placed between the two Tenax®-GC traps and the Anasorb®-747 trap. The first and second traps contain 1.6 g of Tenax®-GC each and the third trap (back trap) contains 5.0 g of Anasorb®-747. A total number of sorbent tube sets to encompass a total sampling time of 2 hrs is collected: i.e., if a sampling rate of 1 L/min for 20 minutes is used, a total of six sorbent tube sets will be collected in 2 hr of sampling.

2.3 Alternative conditions for sample collection may be used, collecting a sample volume of 20 L or less at a flow rate reduced from 1 L/min. (Operation of the SMVOC under these conditions is referred to as SLO-SMVOC.) The SLO-SMVOC may be used to collect 5 L of sample (0.25 mL/min for 20 min) or 20 L of sample (0.5 L/min for 40 min) on each set of sorbent tubes. These smaller sample volumes collected at lower flow rates should be considered when the boiling points of the volatile organic compounds of interest are below 0°C (see Table 1) to prevent breakthrough. Refer to Sec. 2.2 for the total number of tube sets collected per run.

3.0 INTERFERENCES

3.1 Interferences are encountered in the analytical methodology and arise primarily from background contamination of sorbent traps prior to or after sample collection. Other interferences may arise from exposure of the sorbent materials to solvent vapors prior to assembly and exposure to significant concentrations of volatile organic compounds in the ambient air at a stationary source site. To avoid or minimize the low-level contamination of train components with volatile organic compounds, care should be taken to avoid contact of all interior surfaces or train components with synthetic organic materials such as organic solvents, and lubricating and sealing greases. Train components should be carefully cleaned and conditioned according to the procedures described in this protocol. The use of a sealed/enclosed sampling train is suggested but not required (for example, a purged glove bag may be used). The use of blanks (Sec. 6.6) is essential to assess the extent of any contamination. Refer to Method 5041 for additional information on analytical interferences.

3.2 If the emission source has a high level of organic compounds in the emissions matrix (for example, hydrocarbons present at levels of hundreds of ppm), the presence of these volatile organic compounds may interfere with the performance of the SMVOC analytical methodology. If the probability of saturation of the analytical instrumentation exists, preliminary SMVOC screening samples with distributive volumes may be necessary to help ensure that valid and usable data will be obtained. To perform sampling according to distributive volumes, samples of different volumes are collected (typically 5 L, 10 L, and 20 L) to verify that analyte concentrations are 1X, 2X, and 4X.

4.0 APPARATUS AND MATERIALS

4.1 Sampling train - A schematic of the principal components of the SMVOC is shown in Figure 1. The SMVOC consists of a heated glass-lined probe, followed by an isolation valve and charcoal trap, a water-cooled glass condenser, two sorbent tubes containing Tenax®-GC (1.6 ± 0.1 g each), an empty knock-out trap for condensate removal, a second water-cooled glass condenser, a third sorbent tube containing Anasorb®-747 (5.0 g ± 0.1 g), a silica gel drying tube, a calibrated rotameter, a sampling pump, and a dry gas meter. The vacuum during sampling and for leak-checking is monitored by pressure gauges which are in-line with and downstream from the silica gel drying tube. The components of the sampling train are described below.

4.1.1 Probe - The probe is made of stainless steel with a borosilicate or quartz glass liner. The temperature of the probe is maintained at 130°C ± 5°C or higher, but not so high that the sorbent temperature exceeds 20°C. A water-cooled probe may be necessary at elevated source temperatures to protect the probe and meet the required sorbent temperature maximum. Isokinetic sample collection is not a requirement for the use of SMVOC since the compounds of interest are in the vapor phase at the point of sample collection. No nozzle is required, but a plug of clean quartz wool (approximately 2.5 cm. (1 in.)) is inserted in the probe to remove particulate matter.

NOTE: No stainless steel components should be in contact with the sample stream.

4.1.2 Isolation valve - The isolation valve is a greaseless stopcock (0.25 in. outer diameter stem is recommended) with a glass bore and sliding Teflon® plug with Teflon® washers (Ace Glass 8193 or equivalent).

4.1.3 Condensers - The condensers (Ace Glass 5979-14 or equivalent) must be of sufficient capacity to cool the gas stream to 20°C or less prior to passage through the first sorbent tube. The top connection of the condenser must form a leak-free, vacuum-tight seal without using sealing greases. Solverall® tube fittings and screw caps with Solverall® washers (¼ in. OD, or equivalent) are recommended.

4.1.4 Sorbent tubes - See Figure 2 for a diagram of a SMVOC tube.

4.1.4.1 The first and second tubes of a three-tube set of sorbent tubes should each be packed with 1.6 ± 0.1 g of Tenax®-GC resin and the third tube of the set should be packed with 5.0 ± 0.1 g of Anasorb®-747. The tubes should be marked with an arrow to indicate the direction of flow during sampling.

4.1.4.2 The sorbent tubes are glass tubes with approximate dimensions of 10 cm x 1.6 cm ID. The tube is a single glass tube which has the ends reduced in size to accommodate a ¼-in. Swagelok® fitting. The sorbent is held in place by unsilanized clean glass wool at each end of the sorbent layer. Threaded end caps are placed on the sorbent tube after packing with sorbent to protect the sorbent from contamination during storage and transport. In order to minimize tube breakage, fittings are finger-tight plus an additional quarter of a turn. Ceramic-filled Teflon® ferrules (Supeltex M2A or equivalent) are used for tubes. Graphite ferrules (Supeltex M4 or equivalent) are used if reconditioning of the tubes is necessary. The Swagelok® end caps should be finger-tightened with the ferrules in place so that the entire cap assembly may be turned as a unit. In order to seal the assembly and avoid glass breakage, the cap assembly should be pushed to the end of the glass and then backed off slightly before tightening

the cap with a wrench one quarter of a turn. Backing the cap assembly off from the end of the tube will prevent chipping, cracking, or breaking of the glass.

4.1.4.3 The sorbent tubes are placed in transport tubes (capped culture tubes with glass wool and charcoal) for shipment. A layer of clean charcoal is placed in the bottom of the transport tube to absorb any volatile organics in the air in the transport tube. A plug of cleaned glass wool (approximately 2.5 cm. (1 in.)) is placed above the charcoal. The SMVOC tube, with both ends capped, is placed in the transport tube, and a plug of cleaned glass wool (approximately 2.5 cm. (1 in.)) is placed on top of the SMVOC tube. The two glass wool plugs cushion the SMVOC tube during shipping. The transport tube is then sealed tightly with a Teflon®-lined screw cap. At no time, should the samples contained in the sorbent tubes be exposed to large pressure differentials such as might be caused by shipping in unpressurized aircraft cargo compartments.

4.1.5 Metering system - The metering system for SMVOC consists of a vacuum gauge, a pump, a calibrated rotameter for monitoring the sampling flow rate, a dry gas meter (2% accuracy, with a minimum resolution of 0.01 L) at the required sampling rate, needle valves, and a temperature readout device. Provisions should be made for monitoring the temperature of the sample gas stream between the first condenser and the first sorbent tube, since this temperature should not exceed 20°C. The temperature can be monitored by placing a thermocouple on the exterior glass surface of the outlet from the first condenser. The temperature at that point should be less than 20°C. If the cooling is not sufficient, an alternative condenser providing the necessary cooling capacity must be used.

4.1.6 Sample transfer lines - All sample transfer lines connecting the probe to the SMVOC shall be less than 1.52 m. (5 ft.) in length. All sample transfer lines ahead of the first condenser shall be heat-traced Teflon® or glass maintained at 130 ± 5°C. Connecting fittings must be capable of forming leak-free, vacuum-tight connections without the use of sealing grease. All other sample transfer lines used with the SMVOC shall be Teflon® with connecting fittings that are capable of forming leak-free, vacuum-tight connections without the use of sealing grease. These sample transfer lines should not be reused at other emission sources.

4.2 Solverall® washers - All washers or gaskets used in SMVOC shall be Teflon®-coated (Solverall® washers or equivalent; ¼ in. stainless steel Swagelok® fittings with Supeltex M2A ferrules may also be used). Prior to use, these gaskets should be ultrasonically-cleaned with methanol and air-dried in a contained/isolated organic vapor-free area. Gaskets should be stored in clean, screw-capped containers prior to use.

4.3 Glass wool - Glass wool shall be Soxhlet-extracted for 8 to 16 hours using methanol, and oven dried at 110°C before use. Glass wool should not be silanized to prevent contamination of samples with siloxanes. Quartz wool is recommended for high temperature applications.

4.4 Cold packs/ice - Ice or any commercially-available reusable liquids or gels that can be frozen repeatedly are acceptable. These reusable liquids are typically sold in plastic containers as "Blue Ice" or "Ice-Packs". Enough cold packs or ice should be used to maintain tubes less than 10°C. If ice is used as a coolant for the tubes, the tubes should be shielded from direct contact with the ice so they will not become wet when the ice melts. Use of dry ice (solid CO_2) for cooling tubes should be avoided; the sorbent tubes take up carbon dioxide as the solid coolant vaporizes and the analytical system is vented when the tubes are desorbed and analyzed. The tubes should not be stored at freezing temperatures, since the seal between the glass and Teflon® fittings will be compromised and diffusion of volatile organic compounds into the sorbent may occur.

4.5 VOA vials - 40-mL glass vials with Teflon®-lined screw caps are required for recovery of condensate.

4.6 Teflon® squeeze bottles -Teflon® squeeze bottles should be washed with a solution of a laboratory detergent, rinsed with hot tap water, then with distilled water, then rinsed with clean purged water prior to use.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. It is recommended that blanks be taken of all reagents used in testing.

5.2 2,6-Diphenyl-p-phenylene oxide polymer (Tenax®-GC, 35/60 mesh, or equivalent).

5.2.1 New Tenax®-GC is Soxhlet-extracted for 24 hours with methanol. The Tenax®-GC is dried for 6 hours in a vacuum oven at 50°C before use. Thermal conditioning (Sec. 7.1.1) of the Tenax®-GC should be done prior to blanking.

5.2.2 If reuse of Tenax®-GC is necessary, the polymer may be extracted sequentially with methanol and pentane, dried in a vacuum oven, and thermally reconditioned as described above. However, reused tubes must meet the same criteria for cleanliness as new tubes. Reuse of sorbents is not recommended. Common practice in laboratories where SMVOC tubes are prepared commercially or where SMVOC sampling and analysis are done extensively is not to reuse sorbents.

5.3 Anasorb®-747 - New Anasorb®-747 is used as it is received from the manufacturer without preparation other than thermal conditioning pending a Quality Control check (Sec. 7.1.1). Anasorb®-747 must not be reused. The Anasorb®-747 should not be extracted with organic solvent prior to use as a sorbent in the SMVOC.

5.4 Silica gel - Indicating type, 6-16 mesh. New silica gel may be used as received from the vendor. Silica gel should not be reused for SMVOC.

5.5 Methanol, CH_3OH - The methanol used for extracting the Tenax®-GC and glass wool should be pesticide grade or equivalent.

5.6 Organic-free reagent water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 SMVOC glassware cleaning- All glass components of the train should be cleaned thoroughly. The following procedure has been found to be effective, but any protocol which consistently results in contamination-free glassware is acceptable.

6.1.1 Sonicate for 1 hour in a solution of a laboratory detergent such as Alconox®.

6.1.2 Rinse with copious amounts of hot tap water to remove all detergent residue.

6.1.3 Rinse three times with HPLC grade water.

6.1.4 Oven dry at 110°C.

6.1.5 Cap for shipment using Teflon® tape or aluminum foil.

6.2 Assembly

The assembly and packing of the sorbent tubes should be carried out in an area free of volatile organic material, such as a laboratory in which no organic solvents are handled or stored and in which the laboratory air is charcoal filtered. Alternatively, an air-tight sealed glove box is suggested.

6.3 Tenax®-GC tubes

6.3.1 The Tenax®-GC glass tubes and metal tube parts are cleaned and stored (see Sec. 6.1). Ferrules are discarded but the metal unions are cleaned by sonication in methanol. Tenax®-GC (1.6 ± 0.1 g) is weighed and packed into each of the first two sorbent tubes which have unsilanized cleaned glass wool in the downstream end. The Tenax®-GC is held in place by inserting unsilanized cleaned glass wool. Each tube should be marked, using an engraving tool, permanent marker or diamond-tipped pencil, with an arrow to indicate the direction of sample flow during sampling, and a serial number.

6.3.2 Conditioned sorbent tubes are capped and placed on cold packs or ice for storage and transport. The temperature of the tubes during storage and transport is maintained at a temperature of less than 10°C. Conditioned tubes should be held for no more than 14 days before sampling, to prevent the possibility of contamination. At no time, should the samples contained in the sorbent tubes be exposed to large pressure differentials such as might be caused by shipping in unpressurized aircraft cargo compartments.

6.4 Anasorb®-747 tubes - Anasorb®-747 (5.0 ± 0.1 g) is weighed and packed into the third sorbent tube which also has unsilanized cleaned glass wool in the downstream end. The Anasorb®-747 is held in place by inserting unsilanized cleaned glass wool. Special care should be taken to conspicuously mark the Anasorb®-747 tube with an arrow to indicate the direction of flow during sampling, and a serial number.

6.5 Sample collection

6.5.1 For sample collection, place the inlet of the probe at the centroid of the stack or at a point no closer to the walls than 1 meter. After leak checking (see Sec. 6.5.3) but before the initiation of sample collection, the probe shall be purged with stack gas. This purge can be accomplished by attaching a pump to the isolation valve upstream of the first condenser and drawing stack gas through the probe via the isolation valve, so that the probe is purged of ambient air at the initiation of sample collection.

6.5.2 Sample collection is accomplished by opening the valve at the inlet to the first condenser (see Figure 1), turning on the pump, and sampling at a rate of 1 L/min (or slower rate, if desired, according to the guidelines for SLO-SMVOC) for 20 minutes (or an appropriately longer period, if slower sampling rates are used). The volume of sample for any

set of traps should not exceed 20 liters. The end caps of the sorbent tubes should be placed in a clean screw-capped glass container during sample collection to prevent contamination.

6.5.3 Following completion of sample collection, the SMVOC is leak-checked a second time at the highest vacuum encountered during the sampling run to minimize the chance of vacuum desorption of volatile organic compounds from Tenax®-GC. The sample is considered invalid if the leak test does not meet specifications. The train is returned to atmospheric pressure and the set of sorbent tubes is removed. The end caps are replaced and the tubes are placed in an organic-free environment and maintained at a temperature less than 10°C for storage and transport. The set of tubes and any condensate collected (see Sec. 6.5.4) are placed in self-sealing plastic storage bags.

In the laboratory, tubes are maintained in a clean, organic vapor-free environment at a temperature less than 10°C until analysis. The maximum storage time between sampling and analysis of the tubes should be 14 days. The rate of loss of sorbed volatile organic compounds from the tubes is both compound-specific and source-specific. A 14-day period is chosen for the holding time before analysis to provide a reasonably conservative guideline for quantitative analysis of the volatile organic compounds which have been sampled.

NOTE: To prevent breakage and/or loosening of the seals at the end of the tubes, SMVOC tubes should not be stored in a freezer or over dry ice. A solvent-free refrigerator (no cooler than 4°C) is appropriate for storage of the tubes until analysis.

6.5.4 Depending upon condensate volume collected, recovery may be performed with each tube change, or at the end of each run (nominally 2 hrs). Collection of a single composite sample for the run may be especially appropriate when minimal condensate is being collected. If not all the sorbent tubes are analyzed, the total amount of analyte in the composite condensate should be added to the total amount for the run. The condensate is recovered by transferring any liquid contained in the knock-out trap to a 40-mL VOA vial and rinsing the knock-out trap three times with a minimum volume of organic-free reagent water (Sec. 5.6) and adding the rinses to the VOA vial. If necessary, water should be added to eliminate headspace in the vial. If there is sufficient condensate to fill more than one vial, two vials should be used. The VOA vials containing the condensate are placed, with the set of tubes, in a self-sealing plastic storage bag and maintained at a temperature less than 10°C for storage and transport until analysis. The condensate is analyzed by Method 8260. Refer to Method 8260 for details on analytical procedures. Condensate samples, like the sorbent tubes, must be analyzed within 14 days.

6.5.5 A new set of tubes is placed in the SMVOC, the SMVOC is leak-checked, and the sample collection process repeated as described above. To avoid removing the probe from the stack, it is sufficient to perform a glassware leak check using the three way valve just downstream of the probe. Sample collection continues until sufficient samples to encompass a two-hour sampling period have been collected. If samples are taken at a sampling rate of 1 L/minute, a two hour sampling period will result in the collection of six sets of tubes. If SLO-SMVOC procedures are used, fewer than six sets of tubes will be sampled over a two-hour period.

6.6 Blanks

6.6.1 Field blanks - Blank Tenax®-GC and Anasorb®-747 tubes are attached to the sampling train while the train is leak-checked. The tubes are removed and stored with the sample tubes. At least one field blank should be collected for every two-hour sampling period.

6.6.2 Trip blanks - At least one set of blank tubes (two Tenax®-GC, one Anasorb®-747) should be included with each shipment of tubes to a stationary source sampling site. These trip blanks should be treated like any other tubes except that the end caps will not be removed during storage at the site. This set of tubes should be analyzed to assess contamination which may occur during storage and shipment.

6.6.3 Laboratory blanks - One set of blank tubes (two Tenax®-GC, one Anasorb®-747) should remain in the laboratory using the method of storage which is used for field samples. These laboratory blanks should be from the same batch of sorbent as used for the field blanks, trip blanks and collected samples. If the field and trip blanks contain high concentrations of contaminants (e.g., greater than 2 ng of a particular volatile organic compound), the laboratory blank should be analyzed in order to identify the source of contamination.

7.0 PROCEDURE

7.1 Tube conditioning

7.1.1 In a desorption oven, the sorbent tubes are connected to a source of organic-free nitrogen. Nitrogen is passed through each tube at a flow rate of 80-100 mL/min while the tubes are heated. Anasorb®-747 is thermally conditioned for 18-24 hours at 300°C, under a nitrogen flow rate of 80-100 mL/min. Tenax®-GC is thermally conditioned at 220°C for 8-12 hours at a nitrogen flow rate of 80-100 mL/min. The actual length of time required for the conditioning period may be determined based on the adequacy of the resulting blank checks of the conditioned tubes. Method 5041 (modified to use a sorbent desorption temperature of 250°C) and Method 8260 may be used to perform a blank check of each set of sampling tubes to ensure cleanliness.

7.1.2 An acceptable blank level is less than or equal to ($\leq$) Method Detection Limits for Method 5041/8260 (see Method 8260 for Method Detection Limits). A general guideline of analyte values less than 2 ng for any volatile organic compound may be used as a criterion of cleanliness.

7.1.3 After conditioning, tubes are sealed and placed on cold packs or ice (maintained at a temperature less than 10°C) until sampling is completed. Conditioned tubes should be held for no more than 14 days before sampling, to prevent the possibility of contamination.

7.2 Pretest preparation

7.2.1 All train components should be cleaned and assembled as previously described. A dry gas meter should be calibrated within 30 days prior to use, using a standard orifice, or other approved calibration device/meter.

7.2.2 The SMVOC is assembled according to the schematic diagram in Figure 1. Cooling water should be circulated to the condensers and the temperature of the cooling water must be low enough to maintain the temperature of the gas entering the sorbent below 20°C.

7.3 Leak-checking

7.3.1 To leak-check the entire train, it is necessary to leak-check from the probe to the pump. In order to adequately represent actual sampling conditions, a leak-check should be performed with the pump on and the leak rate measured in liters per minute (Lpm) on the dry gas meter. After the desired vacuum is reached, the pump is isolated from the train to check for leaks.

7.3.2 Ensure that all connections are tight and that the train is assembled correctly with sorbent cartridges properly assembled and in the right direction for sampling. Seal the end of the probe and turn the isolation valve to the sample open position. Turn on the pump and adjust the vacuum to 25.4 cm above normal operating pressure (38 cm Hg should be sufficient as 12.7 cm or less is normal). Prior to leak-checking, verify that both the coarse and fine adjust valves on the meter box are partially opened to prevent backflushing of any condensate during final leak checks as the fine adjust valve will need to be adjusted to increase vacuum rather than decrease vacuum. Allow the rotameter on the meter box to drop to zero, allow the dry gas meter to stop, and the pressure on the water column gauge (represents the pressure inside the dry gas meter) to stabilize. The pump is isolated from the train by shutting off the coarse adjust valve. Record the leak rate directly from the vacuum gauge and time for one minute. The leak rate must be less than 0.02 Lpm for 1 Lpm sampling and 0.01 Lpm for sampling at a lower rate.

7.3.3 Upon completion of the leak check, turn off the pump and release the pressure/vacuum in the train by turning the isolation valve to the vacuum release position and allowing ambient air (filtered with charcoal or equivalent) to enter the train. The initial leak check should be above normal operating pressure. The final leak check (following collection of 20 L of sample) should be at least at the highest vacuum encountered during the run.

NOTE: The volume of air pulled through the SMVOC during leak-checking procedures prior to sampling should be less than 2.5% of the total volume sampled. If a volume greater than 2.5% of the total sampling volume is pulled through the SMVOC in obtaining a successful leak check, the sorbent tubes used during this leak check must be discarded and a successful leak check with a minimum volume of gas pulled through the train must be obtained with a new set of sampling tubes in place.

7.4 Sample collection - Sample collection procedures are described in Sec. 6.5.

7.5 Analytical procedure - Samples are analyzed by Methods 5041 and 8260. In these methods, adapted for a three-tube SMVOC, the Tenax® sorbent tubes are spiked with surrogates, internal standards are spiked into the purge water, and the tube(s) thermally desorbed at 250°C under a purge of organic-free helium. The tubes may all be analyzed individually, or the Tenax® tubes may be analyzed as a pair with the Anasorb® tube analyzed separately, or multiple tubes may be combined on one trap for analysis in order to decrease detection limits. The gaseous effluent from the tubes is bubbled through purged organic-free reagent water (Sec. 5.6) and trapped on an analytical sorbent trap in a purge-and-trap unit. After desorption, the analytical sorbent trap is heated rapidly and the gas flow from the analytical trap is directed to the head of a wide-bore capillary column (Method 5041) under subambient conditions. The volatile organic compounds desorbed

from the analytical trap are separated by temperature-programmed gas chromatography and detected by continuously-scanning low resolution mass spectrometry (Method 8260). Concentrations of volatile organic compounds are calculated from a multipoint calibration curve, using the method of response factors. Refer to Method 8260 for details.

7.6 Calculations

7.6.1 The following nomenclature is used in the calculation of sample volume:

P_{bar} = Barometric pressure at the exit orifice of the dry gas meter, mm (in.) Hg.

P_{std} = Standard absolute pressure, 760 mm Hg.

T_m = Dry gas meter average absolute temperature, °K (°R)

T_{std} = Standard absolute temperature, 293°K (528°R)

V_m = Dry gas volume measured by dry gas meter, dcm (dcf)

γ = Dry gas meter calibration factor

$V_{m_{(std)}}$ = Dry gas volume measured by dry gas meter, corrected to standard conditions, dscm (dscf)

7.6.2 The volume of gas sampled is calculated as follows:

$$V_{m_{std}} = V_m \gamma \frac{T_{std} P_{bar}}{T_m P_{std}} = K_1 \gamma \frac{V_m P_{bar}}{T_m}$$

where:

K_1 = 0.3858°K/mm Hg for metric units or

K_1 = 17.64°R/in. Hg for English units.

7.6.3 The concentration of volatile organic compound (CPD) in the stack sample (C_g) is calculated as follows:

$$C_g = \frac{\text{Total weight of CPD in sample, µg (i.e., VOST tubes + condensate)}}{\text{Volume of sample at standard conditions, dscm}}$$

If all three sorbent tubes and the condensate are analyzed separately, four sample results (fewer if some tubes are analyzed together) must be added together to obtain the total weight of CPD. If a measurable amount of the compound is found in one or more fractions of the sample, but the amount in one or more of the other fractions is below detection limit, the following strategy is recommended, but is subject to being overruled by regulatory authorities. Count the "sum of the nondetects" as zero if the sum of the detection limits (in nondetect fractions) is less than 10% of the total of the detected amount from the other fractions. In

cases where the sum of the detection limits in the nondetect fractions is greater than 10% of the amount quantitated in the other fractions, then report the total CPD as greater than the detected amount but less than the detected amount plus the sum of nondetect fraction detection limits.

8.0 QUALITY CONTROL

8.1 Prior to actual sampling on-site, all of the applicable sampling equipment should be thoroughly checked to ensure that each component is clean and operable. Each of the equipment calibration data forms should be reviewed for completeness and adequacy to ensure the acceptability of the equipment. Each component of the sampling system should be carefully packed for shipment. Upon arrival on-site, the equipment should be unloaded, inspected for possible damage, and then assembled for use.

8.2 The following quality control (QC) checks are applicable to the sampling procedures:

8.2.1 Each sampling train must be visually inspected for proper assembly before every use.

8.2.2 All sampling data should be recorded on standard data forms which may serve as a pretest checklist.

8.2.3 The temperature measurement system should be visually checked for damage and operability by measuring the ambient temperature.

8.2.4 All sampling data and calculations should be recorded on preformatted data sheets.

8.2.5 All glassware for SMVOC should be cleaned according to the procedure in Sec. 6.1.

8.2.6 Ten percent of the SMVOC tubes should be subjected to GC/MS QC measurements. No analytes should be detected at concentrations above method detection limits in unused SMVOC tubes. If these quality control tests are performed by the manufacturer, documentation should be obtained from the commercial supplier and retained.

8.2.7 All cleaned glassware, hardware, and prepared sorbent traps should be kept closed with ground-glass caps or Teflon® tape until assembly of the sampling train in the field. The sorbent traps should be recapped immediately after each set of samples is collected.

8.2.8 Prior to sampling, the Tenax®-GC and Anasorb®-747 tubes should be spiked with the compounds of interest to ensure that they can be thermally desorbed under laboratory conditions. This spiking is necessary but not sufficient. The compound must still be sampled from the source.

8.2.9 Assembly and recovery of the sampling trains must be performed in an environment as free from uncontrolled dust and solvent vapors as possible.

8.2.10 Blanks (field, trip, laboratory) must be collected.

8.2.11 The entire sampling train should be leak-checked before and after each run. If the sampling train is moved from one sampling port to another during a run, the train should be leak-checked before and after the move.

8.2.12 Dry gas meter readings, temperature readings, and pump vacuum readings should be made during sampling and recorded in intervals no greater than 5 minutes.

8.2.13 Sorbent traps should be used for sampling within two weeks of preparation.

8.2.14 During sample collection, the gas stream temperature at the inlet to the first sorbent trap must be maintained at or below 20°C.

8.2.15 All sample traps should be stored under refrigeration or on ice or cold packs (temperature maintained less than 10°C) until ready for analysis.

8.3 QC for analytical procedures

8.3.1 Calibration standards should be prepared at five different concentration levels for each analyte of interest. Compounds of interest, surrogate compounds, and internal standards are spiked into the purge water for generation of a multipoint calibration curve. When samples are analyzed, surrogate compounds are spiked onto the sampling tubes using flash vaporization techniques (Method 5041), but internal standards are spiked into the purge water. Response factors for each compound are calculated and these response factors are used for the calculation of analytical results. Refer to Methods 5041 and 8260 for detailed analytical QC procedures for analysis of samples.

8.3.2 To establish the precision and accuracy of the analysis, triplicate paired Tenax®-GC tubes should be spiked with analytical surrogate volatile organic compounds using flash evaporation and analyzed immediately following the initial calibration and before sample analysis. The spiking level should be at the expected level of volatile organic compounds in the stationary source. The spiking standard must be prepared from stock standards separate from those used for calibration. Recovery for each volatile organic compound and surrogate should be within 50% to 150% of spiked value. The relative standard deviation associated with each analyte should be less than 25 percent.

8.3.3 The average recovery from the initial precision and accuracy determinations should be used as an acceptance criterion for sample results. The surrogate recovery in each sample should be within three standard deviations of the average recovery obtained from the initial precision and accuracy determinations.

8.3.4 An EPA performance audit should be completed during a trial burn as a check on the entire SMVOC system. The audit results should agree within 50% to 150% of the expected value for each specific compound of interest. This audit consists of collecting a gas sample containing one or more volatile organic compounds in the SMVOC from an EPA audit gas cylinder. Collection of the audit sample in the SMVOC may be conducted either in the laboratory or at the field test site. Analysis of the SMVOC audit sample must be by the same person, at the same time, and with the same analytical procedure as used for the regular SMVOC samples from the field test.

9.0 METHOD PERFORMANCE

See Method 8260.

TABLE 1

HIGH VOLATILITY ORGANIC COMPOUNDS[a]

Compound	Boiling Point
Bromomethane	4°C
Chloroethane	12°C
Vinyl bromide	16°C, at 750 mm
Vinyl chloride	-13.4°C

[a]Use of SLO-SMVOC may be helpful.

TABLE 2

COMPOUNDS FOR WHICH METHOD 0031 IS NOT APPLICABLE

Compounds	Boiling Point	Comment
Allyl chloride	45°C	Reactive compounds; interacts with test matrix to yield poor recoveries and poor reproducibility
Acetone	56°C	Polar, water soluble
Methyl ethyl ketone	80°C	Polar, water soluble
Chloromethane	-24°C	Reactive compounds; interacts with test matrix to yield poor recoveries and poor reproducibility
Epichlorohydrin	116°C	Not amenable to SMVOC analytical procedure
Chloromethyl methyl ether	56°C	Not amenable to SMVOC analytical procedure
Bis(chloromethyl) ether	106°C	Not amenable to SMVOC analytical procedure
Acetonitrile	82°C	Polar, water soluble
Acetaldehyde	21°C	Polar, water soluble, reactive
Acrolein	53°C	Polar, water soluble, reactive
Methanol	65°C	Polar, water soluble
Ethanol	78°C	Polar, water soluble
Isopropyl alcohol	82°C	Polar, water soluble

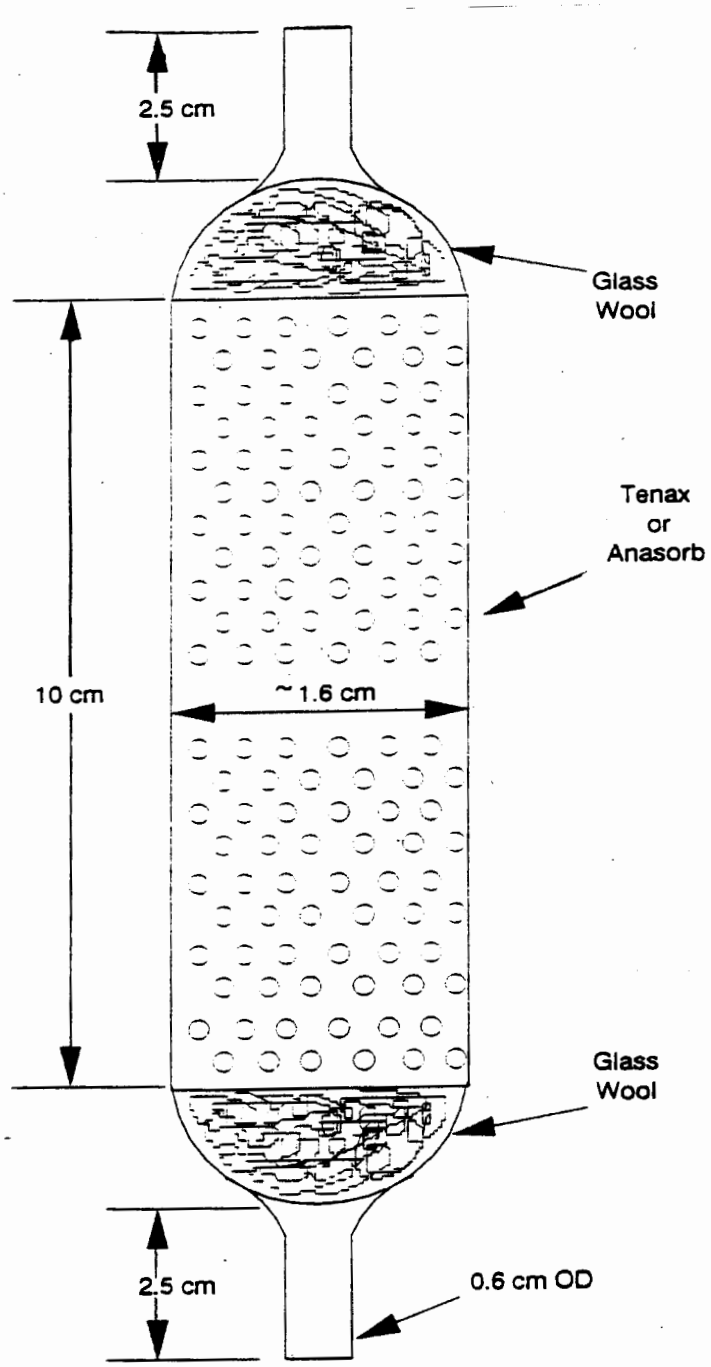
SMVOC TUBE



SAMPLING OF PRINCIPAL ORGANIC HAZARDOUS CONSTITUENTS FROM COMBUSTION SOURCES USING TEDLAR® BAGS

1.0 SCOPE AND APPLICATION

1.1 This method establishes standardized test conditions and sample handling procedures for the collection of volatile organic compounds collected from effluent gas samples from stationary sources, such as hazardous waste incinerators and other combustion sources, using time-integrated evacuated Tedlar® bags. As indicated, the first group of compounds listed below have met Method 301 (Ref. 6) acceptance criteria in a field method evaluation study. The second group of compounds did not meet Method 301 criteria, and the third group of compounds have been identified as candidate analytes from the literature but have not been tested. This is a sample collection method and does not directly address the analysis of these samples. Gas chromatography/mass spectrometry (GC/MS) (Method 8260) is the recommended analytical technique because of its ability to provide positive identification of compounds in complex mixtures such as stack gas.

Compound	CAS Registry No.
Compounds that Met Method 301 Acceptance Criteria in a Field Method Evaluation	
1,1,1-Trichloroethane	71-55-6
Trichloroethene	79-01-6
1,1-Dichloroethane	75-34-3
1,1-Dichloroethene	75-35-4
2,2,4-Trimethylpentane	540-84-1
Allyl chloride	107-05-1
Benzene	71-43-2
Carbon tetrachloride	56-23-5
Methyl chloride	74-87-3
n-Hexane	110-54-3
Methylene chloride	75-09-2
Toluene	108-88-3
Trichlorofluoromethane	353-54-8
Vinyl bromide	593-60-2
Vinyl chloride	75-01-4
Compounds that Did Not Meet Method 301 Acceptance Criteria in a Field Method Evaluation	
Methyl bromide	74-83-9
1,3-Butadiene	106-99-0
Dichlorodifluoromethane	75-71-8
Appropriate Candidate Compounds Not Tested in the Field	
1,2-Dichloro-1,1,2,2-tetrafluoroethane	76-14-2
1,1,2-Trichlorotrifluoroethane	76-13-1
Chloroform	67-66-3
1,2-Dichloropropane	78-87-5
Tetrachloroethene	127-18-4

1.2 This method is not applicable to the collection of samples in areas where there is an explosion hazard. Substitution of intrinsically safe equipment or procedures for the equipment or procedures described in this method will not be sufficient to adapt this method for use in areas where there is an explosion hazard. Additional modifications to the sampling and analytical protocols may be required.

1.3 This method does not employ isokinetic sampling and therefore is not applicable to the collection of highly water soluble volatile organic compounds contained in an aerosol of water. This method uses either a constant or proportional rate sampling, depending upon the extent of the variability of the emission flow rate.

1.4 This method is restricted to use by, or under the close supervision of, trained analytical personnel experienced in sampling organic compounds in air. Each analyst must demonstrate the ability to generate acceptable results with this method.

1.5 Each compound for which this method can be considered shall meet the criteria listed in Secs. 1.5.1 - 1.5.3, below. Table 1 provides boiling points, condensation points (calculated from vapor pressure) at 20°C (72°F), and estimated instrument detection limits for compounds for which applicability of the method has been demonstrated. This method is not limited to the compounds in the target analyte list, however, stability and recovery shall be demonstrated when compounds other than those listed in Sec. 1.1 are to be sampled.

1.5.1 The compound must have a boiling point < 121°C.

1.5.2 The compound must have a concentration in the stack gas below the condensation point.

1.5.3 During validation studies, the loss of the compound from a Tedlar® bag must be less than 20% over a 72-hour storage time at temperatures above 0°C.

1.5.4 This method is not applicable to sources that are under vacuum. Under conditions of sufficiently high positive pressure, it may be possible to force sample gas into the Tedlar® bag causing the gas volume in the bag to be biased high versus the actual meter reading.

2.0 SUMMARY OF METHOD

2.1 A representative sample is drawn from a source through a heated sample probe and filter.

2.2 The sample then passes through a heated 3-way valve and into a condenser where the moisture and condensable components are removed from the gas stream and collected in a trap.

2.3 The sample is collected in a Tedlar® bag held in a rigid, air-tight opaque container.

2.4 The dry gas sample and the corresponding condensate are then transported together to a GC/MS. A mass spectrometer is most suited for the analysis and quantitation of complex mixtures of volatile organic compounds. The total amount of the analyte in the sample is determined by summing the individual amounts in the bag and condensate. A flow chart of the procedure is given at the end of this method.

3.0 INTERFERENCES

3.1 The materials from which the Tedlar® bag is constructed may contribute background hydrocarbon contamination. Purging the bag with air or N_2 may reduce the concentration of these hydrocarbons. Exposure of the bag to direct sunlight may increase the concentration of these hydrocarbons. Therefore, the bag must be protected from exposure to sunlight by using an opaque container to house the bag during sampling and shipping.

3.2 Components of the source emissions other than the target compounds may interfere. Interferents may be differentiated from the target compounds during mass spectrometric analysis.

3.3 Common problems that can invalidate Tedlar® bag sampling data and techniques to remedy these problems are listed in Table 2.

3.4 Available stability data suggest that this method may not perform well in sampling streams containing polar and reactive compounds like methyl ethyl ketone, formaldehyde, methanol, 1-butene, and acetone. The use of this method to sample these compounds needs to be evaluated before sampling.

4.0 APPARATUS AND MATERIALS

4.1 Tedlar® bag sampling train - A detailed schematic of the principal components of the sampling train is shown in Figure 1.

4.1.1 The sampling train (Figure 1) consists of a glass-lined probe, a heated glass or Teflon® filter holder and quartz filter attached to one of two inlets of a glass and Teflon® 3-way isolation valve (Figures 2 and 3). The purge line is connected to a charcoal trap and a silica gel trap, which filters incoming air. The outlet of the isolation valve is connected to a glass, water-cooled coil-type condenser and a glass condensate trap for removal and collection of condensable liquids present in the gas stream. A 1/4-in. OD x 1/8-in. ID Teflon® transfer line connects the condensate trap to a second 3-way isolation valve and the isolation valve to a Tedlar® bag contained in a rigid, air-tight container for sampling, storage, and shipping. The bag container is connected to a control console with 1/4-in. OD x 1/8-in. ID vacuum line by means of 1/4-in. Teflon® connectors at each end. A silica gel trap is placed in the vacuum line between the bag container and the control console to protect the console from moisture during sampling.

4.1.2 The vacuum required to operate this system is provided by a leak-free diaphragm pump contained in the control console (Figure 4). When the pump is turned on, the space between the inner walls of the bag container and the Tedlar® bag is evacuated, placing the system under negative pressure, which pulls the sample through the sampling train and into the Tedlar® bag. The sampling train vacuum is monitored with a vacuum gauge installed in-line between the vacuum line and the coarse adjustment valve mounted in the control console.

4.1.3 Sample flow rate is regulated by adjusting the coarse and fine valves on the control console. The coarse adjustment valve controls the sample inlet volume and rate and isolates the vacuum line, vacuum gauge, and sample train from the pump and other console components during leak checks. Sample volume is monitored by a rotameter, contained in the control console and installed on the outlet side of the dry gas meter.

4.1.4 The source, probe, filter, and condenser temperatures are monitored by Type J or K thermocouples using the temperature readout in the control console. Probe heater temperature is regulated by the temperature controller provided in the control console.

4.1.5 The velocity pressure and temperature of the source gases are measured using a standard or S-type pitot tube connected to a manometer with 1/4-in. OD x 1/8-in. ID tubing, in accordance with Method 2 (see Ref. 9). The source velocity pressure and temperature must be monitored during sampling and the sampling rate adjusted proportionally to changes in the flue gas velocity (Sec. 7.5.2.1).

4.2 Sample train components

4.2.1 Probe assembly - The probe assembly consists of a length of heated and insulated borosilicate glass tube inside a length of stainless steel tubing. The probe temperature shall be maintained between 130°C and 140°C (266°F and 284°F) in order to prevent damage to Teflon® lines and to facilitate efficient cooling of the gases in the condenser. The stainless steel sheath must be cooled with water when the source temperature approaches or exceeds 140°C (284°F).

4.2.2 Particulate filter - Particulate matter from the sample gas stream exiting the probe is collected on a quartz filter substrate in a heated 47-mm Teflon® or glass filter holder. Use clean filters in order to prevent sample contamination. The particulate matter itself is not analyzed or archived. However, removal of the particulate matter provides a cleaner sample for analysis. All connections between the probe and particulate filter shall be heated to maintain the temperature between 130°C and 140°C (266°F and 284°F) so that the compounds remain in the volatile phase. Heat-wrapped Teflon® unions with stainless steel nuts and Teflon® ferrules are recommended for all heated connections.

4.2.3 Isolation valves - A typical isolation valve is shown in Figure 2. The isolation valves shall be constructed of Teflon® or glass with Teflon® stopcocks to provide gas-tight seals without the use of sealing greases. The probe and bag isolation valves are of identical design and materials and are therefore interchangeable. The probe isolation valve provides for the attachment of a charcoal or similar purge trap to allow filtered ambient air to enter the train when returning the train to ambient pressure after leak checks. This valve directly connects the probe and filter assembly to the condenser inlet and must be heated to between 130°C and 140°C (266°F and 284°F). The bag isolation valve allows the bag to be opened for sampling or evacuation and isolated and sealed for leak checks or system purges.

4.2.4 Condenser - Use a jacketed, water-cooled, coil-type glass condenser with a jacket volume of at least 125 mL. The condenser shall have sufficient capacity to maintain the temperature of the sample gas stream between 20°C and 4°C (68°F and 39.2°F) to ensure proper removal and collection of condensable moisture in the effluent gas stream. The cooled sample gas stream temperature should not exceed the coldest temperature to be encountered during sampling, transport and storage prior to analysis. All condenser connections must form a leak-free, vacuum-tight seal without using sealing greases. Stainless steel fittings are not permitted, and Teflon® unions or washers with screw caps are recommended.

4.2.5 Condensate trap - A glass Erlenmeyer distilling flask with threaded screw cap connections, Teflon® seals, and a minimum volume of 125 mL may be used to collect condensate. All connections on the condenser and trap shall be sized to accept 1/4-in. OD x 1/8-in. ID Teflon® or glass fittings. The stem from the condenser must be positioned to within 0.5-in from the bottom of the condensate trap.

4.2.6 Sample transfer lines and connection fittings - All sample transfer lines connecting components shall be less than 5 ft long and constructed of 1/4-in. OD x 1/8-in. ID Teflon® tubing or glass. All sample lines upstream of the condenser and condensate trap must be heated and the temperature maintained between 130°C and 140°C (266°F and 284°F). Use Teflon® fittings for connections between various train components to provide leak-free, vacuum-tight connections without the use of sealing greases. New tubing, which has been cleaned according to Sec. 6.1.2, should be used for each separate test series to prevent cross contamination. Care should be used in the application of excessive heat to Teflon® fittings in order to avoid damage and subsequent failure.

4.2.7 Tedlar® storage bag - Choose a bag size according to the guidelines provided in Sec. 7.2.4. In order to minimize wall effects, the sample volume must fill at least 80% of the bag capacity. The recommended size range for bags is 25 L to 35 L. Small bags (< 25 L) are easier to store and transport but may have insufficient volume for proportional sampling. In addition, accurate volumetric measurement is difficult with smaller bags. Large bags (> 50 L) lack portability, but may be required under certain conditions, such as during proportional sampling and for sampling sources requiring high sample rates.

4.2.8 Evacuated container (bag container) - Use any rigid, air-tight metal or plastic (e.g., PVC®/Polyethylene®/Nalgene®) drums to house the Tedlar® bag during sampling, storage, and transport. The container must be constructed so that it can easily be assembled and disassembled (for bag removal). The container must be able to hold a negative pressure of at least 10 in. H_2O. The bag container must be at least 20% smaller than the Tedlar® bag being used but must be large enough to hold the volume of sample required (e.g., for a sample size of 20 L, a 25-L Tedlar® bag inside a 20-L container provides sufficient volume without danger of overinflating the bag).

Containers must not have staples, sharp edges, or metal closures which might damage bags. The container should also be constructed of a material that shields the sample from exposure to sunlight to protect the bag and its contents from ultra-violet light. A viewing port or other means of observing the flexible bag during sampling is desirable. During storage and transport, the viewing port shall be covered with opaque material.

4.2.9 Vacuum lines - Use Tygon®, Poly®, Nylon®, or similar tubing capable of maintaining at least 10-in. H_2O negative pressure without collapse as vacuum lines. Tubing should be 1/4-in. OD x 1/8 in. ID size to minimize volume and ensure compatibility of connection fittings throughout the train. Stainless steel fittings and valves may be used for vacuum line connections but may not be used in the sampling line.

4.2.10 Control console (meter system) - The metering system required for this method is readily available in the form of the control console/meter box from a Volatile Organic Sampling Train (VOST, Method 0030), and shall consist of the components pictured in Figure 4.

4.2.10.1 Vacuum gauge (meter pressure) - Use a direct reading, mechanical vacuum gauge capable of measuring a vacuum of at least 15 in. Hg with 1-in. or smaller increments to monitor the system vacuum during sampling and leak checking the bag, the container, and the sampling train.

4.2.10.2 Sample flow rate adjustment valves - Coarse and fine adjustment valves are provided. The coarse adjustment valve controls volume and rate of sample flow and isolates the control console from the sampling train and vacuum line during leak

checks. The fine adjustment valve controls sample rate and system vacuum. Closing the valve increases train vacuum and sample flow rate. Opening the valve decreases train vacuum and sample flow rate.

4.2.10.3 Pump - Use a leak-free diaphragm pump or equivalent that is capable of pulling and maintaining a vacuum of at least 15 in. Hg and a flow rate of at least 1 liter per minute (Lpm).

4.2.10.4 Calibrated dry gas meter - The control console contains a calibrated dry gas meter capable of reading 1 L per revolution with 0.1-L increments, and provides accurate measurement of the volume of the sample collected.

4.2.10.5 Flow meter - Use a rotameter with a glass tube and a glass, Teflon®, or sapphire float ball of suitable range to measure the sample flow rate. A range of ± 25% of the desired sampling rate is suggested to ensure greater accuracy of readings and a better range for adjustment of the sampling rate (proportional to the source gas stream velocity). The flow meter shall be accurate to within 5% over the selected range. The rotameter is installed at the outlet of the dry gas meter in the console.

4.2.10.6 Thermocouples and temperature read-out device - Use a sufficient number and length of Type J or K thermocouples. A multi-channel digital thermocouple read-out should be provided in the control console to display the source, probe, filter, condenser, and dry gas meter temperatures.

4.2.10.7 Heat controller - Use a rheostat or digital temperature controller (e.g., Fuji PYZ4 or equivalent) to regulate probe heat temperatures.

4.2.11 Pitot tube probe - A standard or S-type pitot tube must be used for pretest and post-test velocity traverses and to monitor flow so that the sampling rate can be regulated proportionally to the source gas velocity throughout the length of the sampling run.

4.2.12 Pressure gauge (manometer) - Use a water- or oil-filled U-tube or inclined manometer capable of measuring to at least 10 in. H_2O and accurate to within 0.1 in. H_2O for monitoring and measuring the source gas velocity.

4.2.13 Barometer - Use an aneroid or other barometer capable of measuring atmospheric pressure to within 0.1 in. Hg of actual barometric pressure.

4.2.14 Charcoal and silica gel absorbent traps - Use charcoal traps to absorb organic compounds in the atmosphere at the site and an indicating silica gel trap to absorb water. One charcoal trap is attached to the probe isolation valve and filters incoming air when releasing vacuum to prevent contamination of the train during leak checks. Any readily available, ready-made charcoal tube similar to a VOST tube may be used. The silica gel trap is used in the vacuum line to protect the pump from water.

4.2.15 Stopwatch - Use any stopwatch capable of measuring 1 second, to time sample collection.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Water - Water used for sample train preparation shall be distilled and deionized. Water used for rinses during recovery of condensate shall be prepurged high performance liquid chromatography (HPLC)-grade. Clean, clear tap water may be used as condenser cooling water.

5.3 Nitric acid, HNO_3 (10%) - reagent grade.

5.4 Charcoal - SKC petroleum-based charcoal, or equivalent. A mesh size of 6-14 is recommended. New or reused charcoal may be used for each run series or test condition. Reused charcoal must be reconditioned using the same criteria specified in VOST (Method 0030).

5.5 Silica gel - Silica gel shall be indicating type, 6-16 mesh. If the silica gel has been used previously, dry at 175°C (350°F) for 2 hours before using. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used.

5.6 Methanol - Spectrometric-grade, or equivalent.

5.7 Field spiking standards - Appropriate gas cylinders containing the target components of interest in known concentrations (highest purity available) for field spiking.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Pretest preparation

6.1.1 Glassware - Before sampling, prepare the glass components of the train by cleaning with non-ionic detergent (e.g., Alconox) and hot water in an ultrasonic bath. Rinse each component three times with distilled, deionized water, then rinse three times with 10% HNO_3, followed by an additional three rinses with distilled, deionized water. Dry in an oven at 130°C (266°F) for 2 hours.

6.1.2 Sample lines and rigid containers - Treat all Teflon® lines, fittings, and the sample bag containers as outlined in Sec. 6.1.1, but air dry these components in an area free of organic compounds rather than in an oven. Use clean Teflon® tubing for each test series or condition. Hand wash the rigid containers.

6.1.3 Bag cleaning procedure - Ensure that all bags are clean before using them for sampling. First, flush each bag three times with high-purity nitrogen (N_2; 99.998%). Then fill each bag with N_2 and analyze the bag contents at the highest sensitivity setting using the same analytical technique that will be used for analyzing samples. Before constructing the calibration curve, analyze one analytical system blank each day by taking the gas chromatograph through its analytical program with no sample injection. Analyze an analytical system blank again if carryover between samples is indicated. Other, less stringent, methods of cleaning and analysis may be used at the risk of overlooking important contaminants. An acceptable level of contamination will be a response less than five times the instrument detection limit or half

of the level of concern, whichever is less. Repeat the nitrogen flush as necessary until the acceptable level has been reached. No bag shall be used until it has been satisfactorily cleaned.

6.2 Sample bag storage and transport procedures - To ensure sampling integrity, perform sample recovery in a manner that prevents contamination of the bag sample. Protect the bag from sharp objects, direct sunlight and low ambient temperatures (below 0°C [32°F]) that could cause condensation of any of the analytes. Store the bags in an area that has restricted access to prevent damage to or tampering with the sample before analysis. Analyze the bag samples within 72 hours of sample collection unless it can be shown that significant (> 20%) sample degradation does not occur over a longer period of sample storage. Upon completion of the testing and sample recovery, check all the data forms for completeness and the sample bags for proper identification. Store the bags in rigid, opaque containers during all sampling, storage and transport procedures. Ship the bags using ground transportation. Follow all hazardous materials shipping procedures.

6.3 Condensate storage and transport procedures - To ensure sample integrity, perform sample recovery in a manner that prevents the contamination of the condensate (Sec. 7.6.5). Store the condensate in 40-mL vials with no headspace. Place the vials in ice or in a refrigerated container at 4°C (± 2°C) [39.2°F (±7.2°F)] immediately following recovery and during transport for analysis. In addition, store the vials in an area that has restricted access to prevent damage to or tampering with the sample before analysis. Upon completion of the testing and sample recovery, check all the data forms for completeness and the condensate samples for proper identification. Follow all hazardous materials shipping procedures.

6.4 The time lapse between sampling and analysis shall not exceed 72 hours unless it can be justified by specific sample matrix stability data that meet the criteria of Sec. 1.5.3. Stability in a Tedlar® bag shall be demonstrated by spiking analytes into inert gas in the laboratory and into stack gas in the field. The spiking level must be at least at the level found in the samples of the emissions matrix obtained during the pre-site survey. Compound recovery in both laboratory and field studies must be ≥ 80% after 72 hours for consideration of applicability.

7.0 PROCEDURE

The overall sampling procedure involves a pretest survey of the source to establish sampling parameters, a series of pretest checks of the sampling system and the source conditions, and the actual sample collection. These steps are described in Secs. 7.1 - 7.5. Following the actual sample collection step, sampling data are recorded and a post-test leak check is performed (Sec. 7.6). As noted in Sec. 1.0, this method does not include sample analysis procedures, but general guidelines for sample analysis are given in Sec. 7.7. Sec. 7.8 provides an extensive set of calculations associated with the sample collection and analysis procedures.

7.1 Pretest survey

7.1.1 Perform a pretest survey for each source to be tested. The purpose of the survey is to obtain source information to select the appropriate sampling and analysis parameters for that source. Potential interferences may be detected and resolved during the survey. When necessary information about the source cannot be obtained, collection and analysis of actual source samples may be required.

Use the pretest survey data form (Figure 5) to record information gathered during the pretest survey.

7.1.2 The following information must be collected during a survey before a test can be conducted. The information can be collected from literature surveys and source personnel, but an actual on-site inspection is recommended. A copy of the survey results must be forwarded to the staff performing the sample analyses.

7.1.2.1 Determine whether the sampling site is in a potentially explosive atmosphere. If the sample site is located in an explosive atmosphere, use other, intrinsically safe test methods. This method is never to be used in a potentially explosive atmosphere (Sec. 1.2).

7.1.2.2 Measure and record the stack dimensions. Select the sampling site and the gaseous sampling points according to Method 1 (Reference 9) or as specified by the regulatory personnel.

7.1.2.3 Determine the stack pressure, temperature, and the range of velocity pressures using Method 2 (Reference 9). A source with a negative pressure is not suitable for this method.

7.1.2.4 Determine the stack gas moisture content (Sec. 7.2.3) using Approximation Method 4 (Reference 9) or its alternatives. Perform the determination when process operations are as they will be during final sampling. If the process uses and emits ambient air, use a sling psychrometer to measure the moisture content of the ambient air in the area of process air uptake.

7.1.2.5 In accordance with Method 1, select a suitable probe liner and probe length as determined by the temperature and dimensions of the source. Determine the point within the stack that represents an average flow and temperature of the stack. Mark the probe at the determined distance to provide a reference point. For sample collection, insert the probe into the duct to the predetermined point to ensure proper probe placement and collection of a representative sample.

7.1.2.6 Determine whether the source has a constant or variable gas flow rate. The flow rate may be considered constant if the variation over the sampling period is no more than 20%. If the process is constant, use a constant sampling rate (Sec. 7.5.1). If the process is not constant, use proportional sampling (Sec. 7.5.2).

7.1.2.7 Determine approximate levels of target compounds by collecting a pretest bag sample for analysis. This information is needed to establish parameters for the analytical system.

7.1.2.8 Check the sampling site to ensure that adequate electrical service is available.

7.1.2.9 Follow all guidelines in the health and safety plan for the test. Use appropriate safety equipment as required by conditions at the sampling site (e.g., respirator, ear and eye protection, and a safety belt).

7.2 Pretest procedures

7.2.1 Assemble the train according to the diagram in Figure 1. Adjust the probe, filter, and valve heater controls to maintain a temperature between 130°C and 140°C (266°F and 284°F). Circulate cooling water from an ice bath to the condenser until the temperature is

stabilized at or below 20°C (68°F). Allow the probe, filter, valve, and condenser temperatures to stabilize before sampling. Mark the probe, pitot tube, and thermocouple assembly with the proper sampling points as determined in accordance with Method 1. Before sampling, insert the pitot tube and thermocouple probe into the stack, to allow the thermocouple readings to stabilize.

7.2.2 Preliminary velocity and temperature traverse - While the probe, filter, valve, and condenser temperatures are stabilizing, perform a preliminary velocity/temperature traverse in accordance with Methods 1 and 2. Record the velocity (ΔP) and temperature (T, °C) at each point to determine a point of average flow and velocity and measure the static pressure at that point. Determine the average velocity head (ΔP_{avg}) and range of fluctuation.

7.2.3 Determination of moisture content - Determine the moisture content of the gas stream being sampled before (Sec. 7.1.2.4) or during actual sampling. For combustion of water controlled processes (wet electrostatic precipitators and scrubbers), obtain moisture content of the flue gas during test conditions from plant personnel or by direct measurement using Method 4.

7.2.4 Criteria for selection of sample volume and flow rate - The flow rate should fill the bag to at least 80% of its capacity during the sampling period. The following criteria should be met:

7.2.4.1 Minimum stack sampling time for each run should be 1 hr. Data from less than 1 hr of sample collection would be an invalid test run. Two hours of stack sampling time is recommended as optimal.

7.2.4.2 The minimum sample volume shall be at least 15 L.

7.2.4.3 The minimum sample flow rate shall be 250 mL/min.

7.2.4.4 Typically, the average sampling flow rate is about 0.5 L/min, which will collect approximately 30 L of sample per hour.

7.2.4.5 Mass emission rate determination - Determine whether the final result will be presented on a concentration or mass emission basis before sampling. If results will be presented on a concentration basis, only the concentrations of the target analytes and the stack gas moisture content need to be measured. If the mass emission rate of any compound is to be presented, the volumetric flow rate of the stack gas must also be determined. The volumetric flow rate may be determined by performing a temperature and velocity traverse in accordance with Methods 1 and 2, with actual sample collection.

7.3 Leak check procedures

7.3.1 Bag evacuation and bag leak check procedure - Before sampling, ensure that the Tedlar® bag is fully evacuated and leak free.

7.3.1.1 Assemble the sampling train as illustrated in Figure 1 and described in Sec. 4.1.1, ensuring that all connections are tight.

7.3.1.2 Disconnect the vacuum line from the bag container and attach this quick connect fitting to the quick connect fitting on the outlet of the bag isolation valve (Figure

1) and turn on the pump in the control console (Figure 1). Turn bag isolation valve to position 1(Figure 3) and turn on the pump in the control console (Figure 4).

7.3.1.3 Open the coarse adjustment valve and adjust the fine adjustment valve on the control console (Figure 4) until the vacuum gauge reads 5 in. Hg.

7.3.1.4 Observe the dry gas meter and rotameter on the control console as the bag is evacuated. The bag is completely evacuated when no flow is indicated on the dry gas meter and the vacuum rises to 5 in. Hg.

7.3.1.5 Allow the rotameter float ball to drop to zero. Time and record the leak rate using the following procedure.

7.3.1.5.1 Timed leak rate - Observe the leak rate indicated on the vacuum gauge and time for 1 min. The leak rate must be less than 0.1 in. Hg.

7.3.1.6 If all connections are found to be leak tight and the leak rate cannot meet the set criteria, discard the bag and test another clean bag.

7.3.1.7 Turn the bag isolation valve to position 3 (Figure 3) to seal the evacuated bag.

7.3.1.8 Turn off the pump.

7.3.2 Pretest leak check

7.3.2.1 Before sampling and immediately after evacuating and leak checking the bag, perform a pretest leak check of the sampling train.

7.3.2.2 Ensure that the bag isolation valve is in position 3 (Figure 3) and the end of the probe is sealed.

7.3.2.3 Turn the probe isolation valve to position 2 (Figure 3), turn the pump on, and open the coarse adjustment valve(Figure 4).

7.3.2.4 Allow the sampling train to evacuate and adjust the fine adjustment valve to increase the vacuum to 5 in. Hg.

7.3.2.5 When the rotameter drops to zero and the dry gas meter slows to a stop, time and record the leak rate following the procedure outlined in Sec. 7.3.1.5.

7.3.2.6 If the leak rate is greater than 0.1 in Hg/min, check all connections, valves, and the probe seal for tightness. Any leak found must be corrected and the leak check repeated before sample collection begins. It is suggested that new fittings and connections be used when the train is assembled. During the testing, replace as necessary.

7.3.2.7 After completing a satisfactory leak check, return the sampling train to ambient pressure by turning the probe isolation valve to position 3 and turning off the pump.

7.3.2.8 When the vacuum gauge drops to zero, immediately turn the probe isolation valve to position 1. Disconnect the vacuum line from the bag isolation exit quick connect fitting, then attach the vacuum line to the bag container to return the system to the initial state described in Sec. 4.1.1 (Figures 1 and 3).

7.3.3 Post-test leak check

7.3.3.1 A post-test leak check must be performed after each bag sample is collected, before changing the bag and container for the next sample.

7.3.3.2 Ensure that the bag isolation valve is in position 1 (Figure 3) and and the probe isolation valve is in position 1 and the pump is turned off when sample collection is completed.

7.3.3.3 Remove the probe from the stack and seal the end of the probe with a leak-tight seal. Check all connections and train components for looseness or breakage. Do not tighten any connections. Record any abnormal conditions.

7.3.3.4 Disconnect the vacuum line from the container and attach to the outlet of the big isolation valve. Turn the probe isolation valve to position 2. Turn on the pump and adjust the fine adjustment valve until the train vacuum reaches at least 1 in. Hg above the highest vacuum attained during sample collection. Time and record the leak rate as previously outlined in Sec. 7.3.1.5.

7.3.3.5 If the leak rate is less than 0.1 in. Hg/min., the sample is considered valid (Secs. 7.3.1.5.1).

7.3.3.6 Return the sample train to ambient pressure (Secs. 7.3.2.7 and 7.3.2.8) and disconnect the sample and vacuum lines from the bag and container to prepare the train for the next sample.

7.3.3.7 If the post-test leak check proves invalid, discard the invalid sample. Attach a new Tedlar® bag, evacuate and leak check the bag, and repeat the sample collection.

7.4 Preparation for sample collection

7.4.1 Perform the pretest leak checks outlined in Sec. 7.3.

7.4.2 Remove the seal from the end of the probe and insert the probe into the stack to the point of average velocity and temperature and constant flow.

7.4.3 Purge the sampling train (probe, valve, and filter assembly ONLY) using the following procedures.

7.4.3.1 Disconnect the vacuum line quick connect fitting from the rigid bag container (the quick connect fitting has a valve to seal the line).

7.4.3.2 Connect the purge line from the probe isolation valve tee to the vacuum line using the quick connect fittings (Figure 1).

7.4.3.3 Ensure that the probe isolation valve is in position 1 (Figure 3), and turn on the pump.

7.4.3.4 Draw at least eight times the sample volume of flue gas, or purge for at least 10 minutes, whichever is greater.

7.4.4 Adjust the sample flow rate to the desired setting and check all temperature and flow readings during the purge to ensure proper settings.

7.4.5 Purge the sampling train before and between the collection of each sample during the test run.

7.4.6 Label each bag/container and VOA vial clearly, uniquely, and consistently with its corresponding data form and run. Follow appropriate traceability requirements as defined by the regulatory personnel. Return the train to the initial configuration described in Section 4.1.1 (Figure 1) before collecting a sample. First, disconnect the vacuum line quick connect fitting from the purge line quick connect fitting, then reconnect the vacuum line quick connect fitting to the bag container.

7.5 Sample Collection

Start sample collection after the pretest leak check (Sec. 7.3.2) and the system purge (Sec. 7.4). Collect the sample using proportional rate sampling if the pretest survey measurements (Sec. 7.1.2.7) show that the emission flow rate varies by more than 20% over the sampling period. Otherwise, use constant rate sampling. Prepare for sample collection for either method by turning the probe isolation valve to position 2 for sampling and the bag isolation valve to position 2 while the pump is still running from the system purge.

If a viewing port has been incorporated in the bag container design, visually inspect the Tedlar® bag frequently during the sampling run to ensure that it is filling properly and that a sufficient sample volume is collected. This frequent inspection will also help prevent overfilling and bursting the bag during sampling. Use the field sampling data form (Figure 6) to record sample collection data.

7.5.1 Constant rate sampling

7.5.1.1 Place the end of the probe at a point within the duct determined to have the average velocity and temperature and a constant flow rate.

7.5.1.2 Record the start volume from the dry gas meter and begin timing the sample period.

7.5.1.3 Take flue gas velocity and temperature readings using either Method 2A for smaller ducts (< 24 inches) with a remote pitot tube and thermocouple or Method 2 for larger ducts (> 24 inches). Utilizing a sample probe with pitot tubes and thermocouples attached will generally ease sampling and will provide a direct means to monitor flue gas velocity and temperature at the sample probe inlet.

7.5.1.4 Record all required data upon starting, and at intervals of no more than 5 minutes on the field sampling data form.

7.5.1.5 Adjust the sample flow rate and sampling train heating systems to the correct levels, after every velocity and temperature reading. The tester must closely monitor the sample train and control console to ensure that the sample flow rate does not vary by more than 20% during any 5-minute period.

7.5.2 Proportional sampling

7.5.2.1 Position the probe in the center of the stack.

7.5.2.2 Record the start volume from the dry gas meter and begin timing the sample period.

7.5.2.3 Monitor the velocity head during sampling as described in Sec. 4.1.5 and maintain a constant proportion between the sample flow rate and the flow rate in the duct. The flow rate to be used during sampling (Sec. 7.2.2) is calculated using the proportional sample rate equation in Sec. 7.8.4. With this equation and the sample rate assigned to the average flow rate, the rotameter setting can be determined after each velocity reading and the sample rate set accordingly.

7.5.2.4 Record all required data upon starting, and at intervals of no more than 5 minutes on the field sampling data form.

7.5.3 Single-point sampling

Collect samples from a single point within the duct as described in Secs. 7.5.1.1 and 7.5.1.2, unless multipoint sampling has been determined necessary (Sec. 7.5.4).

7.5.4 Multipoint sampling

Perform multipoint integrated sampling only in a case where there is a possibility of effluent stratification. Stratification of gases is less likely than of particulates. If however, multipoint sampling is required, determine the necessary number of sample points in accordance with Methods 1 and 2.

7.6 Post-test procedures

7.6.1 Record the final volume from the dry gas meter at the end of each sample collection period.

7.6.2 Perform a post-test leak check as described in Sec. 7.3.3.

7.6.3 Inspect the field sampling data form and sample identification labels for accuracy and completeness.

7.6.4 Replace the particulate filter after each sample.

7.6.5 Condensate Recovery - The condensate collected during sampling must be recovered separately for each individual bag sample collected, using the following procedures.

7.6.5.1 Carefully remove the condensate trap, the condenser and the sample line (from the trap to the bag) from the sample train. Pour the contents of the condensate trap into a clean measuring cylinder.

7.6.5.2 Rinse the condenser, the condensate trap and the sample line three times with 10 mL of HPLC grade water and add the rinsings to the measuring cylinder containing the condensate. Record the final volume of the condensate and rinse mixture on the field sampling data form. High moisture sources (such as those with wet control devices) may require a 150-mL or 200-mL measuring cylinder while low moisture sources (such as some rotary kilns and pyrolytic incinerators) may require only a 100-mL size.

7.6.5.3 Pour the contents of the measuring cylinder into a 20- or 40-mL amber glass VOA vial with a Teflon® septum screw cap. Fill the vial until the liquid level rises above the top of the vial and cap tightly. The vial should contain zero void volume (i.e., no air bubbles). Discard any excess condensate into a separate container for storage and transport for proper disposal.

7.6.5.4 Label each vial by using wrap-around labels. Labels can be preprinted or can be filled out on site.

7.7 Analytical Approach

The following description provides general guidelines to the analytical approach rather than a comprehensive analytical approach. The primary analytical tool recommended for the measurement of volatile organic compounds in source emissions is GC/MS using fused-silica capillary GC columns such as described in Method 8260. Prescreening of the sample by gas chromatography with either flame ionization (GC/FID) or, for electronegative compounds, electron capture detection (GC/ECD) is recommended because it may not only be cost effective, but will also yield information regarding the complexity and concentration of the sample. If the smallest feasible injection loop saturates the analytical system, dilutions of the sample can be made into Tedlar® bags using pure N_2 (99.998%) as diluent. Calculate the concentration of the volatile organic compounds in the gaseous emissions by using the equations (13-17) in Sec. 7.8.

7.7.1 Analysis of gaseous components - Introduce the gases into the gas chromatograph through the use of a sample loop. Use a cryogenic trap if sample concentration before analysis if necessary.

For most purposes, electron ionization (EI) mass spectra will be collected because a majority of the volatile organic compounds give characteristic EI spectra. Also, EI spectra are compatible with the NIST Library of Mass Spectra and other mass spectral references, which aid in the identification process for other components in the incinerator process streams.

To clarify some identifications, chemical ionization (CI) spectra using either positive ions or negative ions can be used to elucidate molecular-weight information and simplify the fragmentation patterns of some compounds. In no case, however, should CI spectra alone be used for compound identification. For descriptions of GC conditions, MS conditions, internal standard usage, and qualitative and quantitative identification, refer to Method 8260.

7.7.2 Analysis of condensates - Refer to Method 5030 to analyze condensate samples by using the purge and trap technique or by direct aqueous injection. Use direct solvent injection if an organic phase is present distinct from the aqueous phase. Use dilution as necessary to prevent saturation of the analytical system.

7.8 Calculations

7.8.1 Carry out all calculations for determining the concentrations and emission rates of the target compounds. Round off figures after final calculations to three significant figures.

7.8.2 Nomenclature

A = Stack/source cross sectional area, m^2 (ft^2)

A_B = Amount of volatile organic compound in bag (ng)

A_c = Amount of volatile organic compound in condensate (ng)

A_{vol} = Amount of volatile organic compound in analytical sample (ng)

A_T = Total amount of volatile organic compound (ng), $A_B + A_C$

B_{ws} = Water vapor in the gas stream, proportion by volume (x100=% H_2O)

C_P = Type S pitot tube coefficient (nominally 0.84 ± 0.02), dimensionless.

$C_{Emission}$ = Concentration of volatile organic compound in emissions (ng/mL)

C_{vol} = Concentration of volatile organic compound per volume sampled (ng/mL)

C_{spike} = Concentration of spiking standard in the Tedlar® bag (ng/mL or µg/L)

C_{stock} = Concentration of spike standard in the stack/audit cylinder.

$DV_{eff(std)}$ = Volumetric flow rate of exhaust gas,m^3/min, ft^3/min.

K_p = Pitot tube constant,

$$34.97\,\text{m/sec}\left[\frac{(\frac{g}{gmole})(mmHg)}{(K)(mmH_2O)}\right]^{1/2}$$

$$85.49\,\text{ft/sec}\left[\frac{(\frac{lb}{lbmole})(inHg)}{(^{O}R)(inH_2O)}\right]^{1/2}$$

L_a = Maximum acceptable leakage rate for a leak check following a component change; less than or equal to 0.1 in. Hg.

LDL_{vol} = Lower detectable amount of volatile organic compound in entire sampling train.

L_i = Individual leakage rate observed during the leak check conducted before to the "i^{th}" component change (i = 1, 2, 3...n), L/min.

L_p = Leakage rate observed during the post-test leak check,in. Hg/min.

Max $Mass_{vol}$ = Maximum allowable mass flow rate (g/hr [lb/hr]) of volatile organic compound emitted from the combustion source.

Max $Conc_{vol}$ = Maximum anticipated concentration of the volatile organic compound in the exhaust gas stream, g/m^3 ($lb\ ft^3$).

M_d = Stack-gas dry molecular weight, g/g-mole (lb/lb-mole).

M_{fd} = Dry mole fraction of the flue gas.

M_s = Wet molecular weight of the flue gas, g/g-mole (lb/lb-mole).

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).

P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg).

P_g = Flue gas static pressure, mm H_2O (in. H_2O).

P_k = Specific gravity of mercury (13.6)

P_m = Dry gas meter pressure, inches H_2O

P_s = Absolute stack gas pressure, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

Q_m = Average sampling rate, L/min.

Q_s = Calculated sampling rate, L/min.

Q_{sd} = Volumetric air flow rate, (m^3/min, ft^3/min).

R = Ideal gas constant, 0.06236 mm Hg-m^3/K-g-mole (21.85 in. Hg-ft^3/°R-lb-mole).

T_m = Absolute average dry gas meter temperature, K (°R).

T_s = Absolute average stack gas temperature, K (°R).

T_{std} = Standard absolute temperature, 293 K (528°R).

V_A = Analytical sample volume (mL).

V_B = Bag volume (mL).

V_i = Concentration of volatile organic compound (wt %) introduced into the combustion process.

V_i conc = Anticipated concentration of the volatile organic compound in the exhaust gas stream, g/L (lb/ft^3).

V_{lc} = Total volume of liquid collected in the condensate knockout trap.

V_m = Volume of gas sample as measured by dry gas meter, L.

$V_{m(std)}$ = Volume of gas sample measured by dry gas meter, corrected to standard conditions, L.

V_{spike} = Volume of gaseous or liquid spiking standard (mL)

V_{TBC} = Minimum dry standard volume to be collected at dry gas meter.

V_T = Train sample volume (mL)

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, L (ft^3).

V_s = Stack gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 4, m/sec (ft/sec).

WF = Mass flow rate of waste feed per hour, g/hr (lb/hr).

γ = Dry gas meter calibration factor, dimensionless.

ΔP = Actual velocity pressure, mm (in.) H_2O.

ΔP_{avg} = Average velocity pressure, mm (in.) H_2O.

ρw = Density of water, 0.9982 g/mL (0.002201 lb/mL).

θ = Total sampling time, min.

θ_i = Sampling time interval of each successive component change, beginning with the interval between the start of the run and the first component change, min.

θ_p = Sampling time interval from the final (n^{th}) component change until the end of the sampling run, min.

60 = Second/minute conversion.

100 = Conversion to percent.

7.8.3 Conversion factors

From	To	Multiply by
ft^3	L	0.02832

7.8.4 Proportional sample rate calculation. The flow rate to be used during sampling when the velocity head varies from the average is calculated using the following equation:

$$Q_s = Q_m \frac{\sqrt{\Delta P}}{\sqrt{\Delta P_{Avg}}} \quad (1)$$

7.8.5 Dry gas volume: Correct the sample measured by the dry gas meter to standard conditions (20°C, 760 mm Hg [68°C, 29.92 in. Hg]) by using the following equation:

$$V_{m(std)} = V_m \gamma \frac{T_{std}}{T_m} \frac{P_{bar} + P_M/13.6}{P_{std}} = K_1 V_m \gamma \frac{P_{bar} + P_M/13.6}{T_m} \quad (2)$$

where:

K_1 = 0.3858 K/mm Hg for metric units, or

K_1 = 17.64°R/in. Hg for English units.

Equation 2 can be used as written, unless the leakage rate observed during any of the mandatory leak checks (i.e., the post-test leak check or leak checks conducted before component changes) exceeds L_a. If L_p or L_i exceeds L_a, Equation 2 must be modified as follows (with the approval of the appropriate regulatory personnel):

7.8.5.1 Case I (no component change made during sampling run)

Replace V_m in Equation 2 with the expression:

$$V_m - \left[(L_p - L_a)\right] \theta \quad (3)$$

7.8.5.2 Case II (one or more component changes made during the sampling run)

Replace V_m in Equation 2 with the expression:

$$V_m - \left(\sum_{i=1}^{n} (L_i - L_a)\theta_1 \right) - (L_P - L_a)\theta_p \quad (4)$$

and substitute only for those leakage rates (L_i or L_p) that exceed L_a.

7.8.6 Volume of water vapor

$$V_{w(std)} = V_{lc} \frac{\rho_w}{M_w} \frac{RT_{std}}{P_{std}} = K_2 V_{1c} \quad (5)$$

where:

K_2 = 0.001333 m^3/mL for metric units, or

K_2 = 0.04707 ft^3/mL for English units.

7.8.7 Moisture content

$$B_{ws} = \frac{V_{w\ (std)}}{V_{m\ (std)} + V_{w\ (std)}} \quad (6)$$

7.8.8 Volumetric flow rate equations

7.8.8.1 Static pressure

$$P_s = P_{Bar} + \left(\frac{P_g}{P_k} \right) \quad (7)$$

7.8.8.2 Dry molecular weight

$$M_d = (\%\ CO_2 \times 0.44) + (\%\ O_2 \times 0.32) + [(\%\ CO + \%\ N_2) \times 0.28] \quad (8)$$

7.8.8.3 Dry mole fraction

$$M_{fd} = 1 - B_{ws} \quad (9)$$

7.8.8.4 Wet molecular weight

$$M_s = (M_d \times M_{fd}) + (18 \times B_{ws}) \quad (10)$$

7.8.8.5 Flue gas velocity

$$V_s = k_P\ C_P\ (\sqrt{\Delta P})_{avg} \left(\frac{T_{s(avg)}s}{M_s P_s} \right)^{½} \quad (11)$$

7.8.8.6 Volumetric flow rate

$$DV_{eff(std)} = 60\ V_s\ M_{fd}\ A \left(\frac{T_{std}}{T_{s(avg)}} \right) x \left(\frac{P_s}{P_{std}} \right) \quad (12)$$

7.8.9 Concentration of a volatile organic compound in the gaseous emissions of a combustion process.

7.8.9.1 Divide the amount of volatile organic compound determined through analysis by the volume of sample introduced into the analytical system to obtain concentration of the volatile organic compound in the bag or the condensate.

$$C_{vol} = \frac{A_{vol}}{V_A} \quad (13)$$

7.8.9.2 Multiply the concentration of the volatile organic compound (ng/mL) by the sample volume (bag or condensate) to determine the amount of the volatile organic compound in the bag or condensate.

$$A_B = C_{vol}\ x\ V_B \quad (14)$$

or

$$A_C = C_{vol}\ x\ V_{lc} \quad (15)$$

7.8.9.3 Sum the amount of volatile organic compound found in all samples associated with a single train.

$$A_T = A_B + A_C \quad (16)$$

The mass of each compound from the A fraction is added to that from the B fraction to obtain a train total before further calculation. If a measurable amount of the compound is found in one fraction, but the amount in the second fraction is below detection limit, the following strategy is recommended, but is subject to being overruled by regulatory authorities. Count the "nondetect" as zero if the detection limit is less than 10% of the total of the detected amount from the other fraction, but in cases where the detection limit in the second fraction is greater than 10% of the amount detected in the first fraction, then report the total as greater than the detected amount but less than the detected amount plus the second fraction detection limit.

7.8.9.4 Divide the total amount found by the volume of stack gas sampled to determine the concentration of the volatile organic compound in the gaseous emissions.

$$\frac{A_T}{V_T} = C_{Emission} \quad (17)$$

7.8.10 Concentration of the spiking standard in the Tedlar® bag

$$C_{spike} = \frac{V_{spike} \text{ X } C_{stock}}{V_B} \quad (18)$$

7.8.11 Recovery of the spiking standard from the Tedlar® bag sample

$$\% \text{ Recovery} = \frac{C_{vol}}{C_{spike}} \text{ X } 100 \quad (19)$$

8.0 QUALITY CONTROL

8.1 Quality assurance/quality control requirements before sampling

8.1.1 Pitot tube probe - Before sampling, assemble and calibrate the pitot tube probe (described in Sec. 4.2.11) in accordance with Method 2. Leak check above the static stack pressure. The pitot tube assembly must be leak free (0.00 in. H_2O in 1 minute).

8.1.2 Pressure gauge (manometer) - Calibrate the pressure gauge (described in Sec. 4.2.12) in accordance with Method 2. Leak check the pitot tubes, pressure gauge, and pitot tube lines simultaneously, as a unit, before the velocity traverse.

8.1.3 Thermocouple and temperature read-out device - Calibrate these devices (described in Sec. 4.2.10.6) within 30 days of sampling and in accordance with Method 2. The thermocouple and temperature read out must be accurate to ± 1°C.

8.1.4 Metering system - Calibrate the dry gas meter contained in the control console in accordance with the procedures outlined in Method 5. Calibrate the meter at a flow rate appropriate for the sampling rate used during the test.

8.1.5 Probe heater - Calibrate the probe heater before sample collection following procedures outlined in Method 5.

8.1.6 Barometer - Record the barometric pressure at the test site before each test. Alternatively, obtain the barometric pressure from a local weather service and correct it to the altitude of the test site if the reporting center is at a different altitude.

8.2 Blanks and field spikes

Field, trip and laboratory blanks, contamination checks and field spiked samples are required to monitor the performance of the sampling method and to provide the required information to take corrective action if problems are observed in the laboratory operations or in field sampling activities.

8.2.1 Field blanks - Take at least one field blank sample daily and per source. Collect high purity air or N_2 (99.998%) from a compressed gas cylinder in the same manner as source

emissions. Draw the air or nitrogen gas through the sampling system and into the bag. Field blank samples shall consist of the condensate and a bag sample. Transport and analyze this blank sample along with the stack gas samples. When the field blank values are greater than 20% of the stack values, flag the data. Report the field blank values with the stack gas results. A condensate blank is prepared by filling a vial with HPLC-grade water. The condensate blank is transported and analyzed with the stack gas condensate samples. When the field condensate blank values are greater than 20% of the stack values, flag the data.

8.2.2 Trip blanks - Take at least two Tedlar® bags labeled "trip blanks" and filled with an inert gas to the sampling site. These bags will be treated like any other samples except that they will not be opened during storage at the site. These bags will be subsequently analyzed to monitor potential contamination which may occur during storage and shipment.

8.2.3 Laboratory blanks - Leave two Tedlar® bags labeled "laboratory blanks" in the laboratory using the method of storage that is used for the field samples. If the field and trip blanks contain high concentrations of contaminants (i.e., greater than five times the detection limit of particular analyte), the laboratory blank shall be analyzed to identify the source of contamination.

8.2.4 Tedlar® bag contamination checks - The use of new bags for each test series is recommended. All bags must be cleaned and checked for contamination before being used for sampling (Sec. 6.1.3).

8.2.5 Field spike samples - Take at least one field spike per 10 field samples, or a minimum of one field spike per test. Spike the chosen bag sample with a known mixture (gaseous or liquid) of isotopically labeled analogs of all the target pollutants using either gaseous or liquid injection into the bag. Transport and analyze the spiked sample with the stack gas samples. Report the spike sample recoveries with the source test results. The compound recoveries in the spiked sample must be 80 - 120%. Use Equation 19 in Sec. 7.8.11 to calculate spiking compound recovery.

The spiking concentration should be at least twice the concentration anticipated in the emissions matrix. Use Equation 18 in Sec. 7.8.10 to calculate the spiking concentration. The syringe volume for the gaseous injection should not exceed 200 mL to minimize leakage through the septum after injection. For liquid injections, the volume injected must not exceed 1 mL to ensure complete volatilization. The final volume of the spiked gas must not exceed 1% of the total sample volume. Use the ideal gas equation to calculate the volume of gas generated by a liquid injection into the bag.

8.2.5.1 Obtain spiking stock that is sufficiently concentrated to spike a Tedlar® sample without exceeding the 1% volume limit. Select appropriate analytes, analyte homologs, or isotopically labeled analogs in cylinders or SUMMA® canisters for gaseous injections or neat liquids or methanol solutions for liquid injections.

8.2.5.2 Install an injection port that consists of a Swagelok® tee fitting with a septum in the sample line just before the 1/4-in. Quick connector on the Tedlar® bag (Figure 1). Locate this port as close to the bag as possible to minimize wall effects. Use a new septum for each sampling run that involves spiking.

8.2.5.3 Perform a leak test as described in Sec. 7.3 with the injection port in line.

8.2.5.4 Start sampling the stack as described in Secs. 7.4 and 7.5.

8.2.5.5 In preparation for injection, clean the syringe by flushing three times with an inert gas (high purity N_2, 99.998%) for gaseous injections, or with methanol for liquid injections. Then flush the syringe three times with the gaseous or liquid spiking standard.

8.2.5.6 After half an hour of sample collection, take up the desired volume of the spiking standard into the syringe (for gases, allow the standard to equilibrate to atmospheric pressure) and inject it through the septum into the bag without interrupting the sampling procedure. All apparatus upstream of the bag should be under slight negative pressure.

8.3 An EPA performance audit shall be completed during a trial burn as a check on the entire Tedlar® bag sampling system. The audit results should agree within 50% to 150% of the expected value for each specific compound of interest. This audit consists of collecting a gas sample containing one or more volatile organic compounds in the Tedlar® bag sampling system from an EPA audit gas cylinder. Collection of the audit sample in the Tedlar® bag sampling system may be conducted either in the laboratory or at the field test site. Analysis of the Tedlar® bag audit sample must be by the same person, at the same time, and with the same analytical procedure as used for the regular Tedlar® bag samples from the field test.

8.4 Evaluation of analytical procedures for a selected series of compounds shall include the sample preparation procedures and each associated analytical determination. Challenge the analytical procedures by spiking the test compounds at appropriate levels carried through the procedures.

8.5 Determine the overall method detection limits (lower and upper) on a compound-by-compound basis according to the 40 CFR Part 136b for the determination of the detection limit. Different compounds may exhibit different collection efficiencies as well as instrumental minimum detection limit.

8.6 During the sampling planning stage, determine whether each compound on the analyte list has been validated for this method at a similar source. For all compounds which have not, either plan to determine the method precision and bias by dynamic spiking ahead of the filter in accordance with Method 301 (Reference 6) or present a justification for not running Method 301 to appropriate regulatory personnel. The justification may be based on previous validation of one or more compounds very similar to those in question, or on other technical issues as appropriate.

9.0 METHOD PERFORMANCE

Method evaluation data are available from testing at a coal-fired power plant (Reference 10). Compounds which met method validation criteria are shown in Sec. 1; compounds which were tested and failed to meet method validation criteria are also shown in Sec. 1.

1,2-Dichloropropane	78-87-5	96	5	0.05
Toluene	108-88-3	111	3	0.08
Tetrachloroethylene	127-18-4	121	2	0.03

[a]Since this value represents a direct injection (no concentration) from the Tedlar® bag, these values are directly applicable as stack detection limits

TABLE 2

PROBLEMS THAT CAN INVALIDATE TEDLAR® BAG SAMPLING
DATA AND SUGGESTED REMEDIES

Problem	Remedy
1. Condensation of the gases or water vapor in the bag	Sample below the condensation point of the analytes; lower the temperature in the condensate trap.
2. Leaks developing in the bag during testing, transport, and/or analysis	Use double sealed bags; perform additional sampling runs; protect the bags from sharp objects by sampling and shipping in rigid, opaque containers; ship the bags in the same containers used during sampling.
3. Hydrocarbon contamination	Minimize exposure of the bag to heat and direct light, by sampling and shipping in rigid, opaque containers; purge the bags with ultrapure N_2 in the laboratory and establish through analysis that the hydrocarbon levels are acceptable; use the bags only once.

METHOD 0050

ISOKINETIC HCl/Cl_2 EMISSION SAMPLING TRAIN

1.0 SCOPE AND APPLICATION

1.1 This method describes the collection of hydrogen chloride (HCl, CAS Registry Number 7647-01-0) and chlorine (Cl_2, CAS Registry Number 7782-50-5) in stack gas emission samples from hazardous waste incinerators and municipal waste combustors. The collected samples are analyzed using Method 9057. This method collects the emission sample isokinetically and is therefore particularly suited for sampling at sources, such as those controlled by wet scrubbers, emitting acid particulate matter (e.g., HCl dissolved in water droplets). A midget impinger train sampling method designed for sampling sources of HCl/Cl_2 emissions not in particulate form is presented in Method 0051. The method has potential for collection of all halogens and halogen acids, but has not yet been fully evaluated for that use. For analytical determination of additional halides, Method 9056 is used, rather than Method 9057.

1.2 This method is not acceptable for demonstrating compliance with HCl emission standards less than 20 ppm.

1.3 This method may also be used to collect samples for subsequent determination of particulate emissions (Method 5, see Ref. 1) following the additional sampling procedures described.

2.0 SUMMARY OF METHOD

2.1 Gaseous and particulate pollutants are withdrawn from an emission source and are collected in an optional cyclone, on a filter, and in absorbing solutions. The cyclone collects any liquid droplets and is not necessary if the source emissions do not contain liquid droplets. The Teflon mat or quartz-fiber filter collects other particulate matter including chloride salts. Acidic and alkaline absorbing solutions collect gaseous HCl and Cl_2, respectively. Following sampling of emissions containing liquid droplets, any HCl/Cl_2 dissolved in the liquid in the cyclone and/or on the filter is vaporized to gas and ultimately collected in the impingers by pulling Ascarite II^R conditioned ambient air through the sampling train. In the acidified water absorbing solution, the HCl gas is solubilized and forms chloride (Cl^-) ions. The Cl_2 gas present in the emissions has a very low solubility in acidified water and passes through to the alkaline absorbing solution where it undergoes hydrolysis to form a proton (H^+), Cl^-, and hypochlorous acid (HClO). The (Cl^-) ions in the separate solutions are measured by ion chromatography (Method 9057). If desired, the particulate matter recovered from the filter and the probe is analyzed following the procedures in Method 5.

2.2 The stoichiometry of HCl and Cl_2 collection in the sampling train is as follows: In the acidified water absorbing solution, the HCl gas is solubilized and forms chloride ions (Cl^-) according to the following formula:

$$HCl + H_2O = H_3O^+ + Cl^-$$

The Cl_2 gas present in the emissions has a very low solubility in acidified water and passes through to the alkaline absorbing solution where it undergoes hydrolysis to form a proton (H^+), Cl^-, and hypochlorous acid (HClO) as shown:

$$H_2O + Cl_2 = H^+ + Cl^- + HClO$$

Sodium thiosulfate solution is added to the contents of the hydroxide filled impingers, in order to promote the following reaction.

$$S_2O_3^{-2} + 4OCl^- + 2OH^- = 2SO_4^{-2} + 4Cl^- + H_2O$$

Conversion of all the original Cl_2 to the stable Cl^- ion, and appropriate adjustment of the analysis calculations, removes the possibility of partial reduction of OCl^- to Cl^- and the resulting high bias to the results.

3.0 INTERFERENCES

3.1 Volatile materials which produce chloride ions upon dissolution during sampling are obvious interferences in the measurement of HCl. One interferant for HCl is diatomic chlorine (Cl_2) gas which disproportionates to HCl and hypochlorous acid (HClO) upon dissolution in water. Cl_2 gas exhibits a low solubility in water, however, and the use of acidic rather than neutral or basic solutions for collection of hydrogen chloride gas greatly reduces the dissolution of any chlorine present.

4.0 APPARATUS AND MATERIALS

4.1 Sampling Train.

4.1.1 A schematic of the sampling train used in this method is shown in Figure 1. This sampling train configuration is adapted from Method 5 and Method 0010 procedures, and, as such, the majority of the required equipment is identical to that used in Method 0010 determinations. The new components required are a glass nozzle and probe, a Teflon union, a quartz-fiber or Teflon mat filter (see Section 5.5), a Teflon frit, and acidic and alkaline absorbing solutions.

4.1.2 Construction details for the basic train components are provided in Section 3.4 of EPA's Quality Assurance Handbook, Volume III (Reference 2); commercial models of this equipment are also available. Additionally, the following subsections identify allowable train configuration modifications.

4.1.3 Basic operating and maintenance procedures for the sampling train are also described in Reference 2. As correct usage is important in obtaining valid results, all users should refer to Reference 2 and adopt the operating and maintenance procedures outlined therein unless otherwise specified. The sampling train consists of the components detailed below.

4.1.3.1 Probe nozzle. Glass with sharp, tapered (30° angle) leading edge. The taper shall be on the outside to preserve a constant I.D. The nozzle shall be buttonhook or elbow design. The nozzle should be coupled to the probe liner using a Teflon union. It is recommended that a stainless steel nut be used on this union. In cases where the stack temperature exceeds 210°C (410°F), a one-piece glass nozzle/liner assembly must be used. A range of nozzle sizes suitable for isokinetic sampling should be available. Each nozzle shall be calibrated according to the procedures outlined in Method 5.

4.1.3.2 Probe liner. Borosilicate or quartz-glass tubing with a heated system capable of maintaining a gas temperature of 120 ± 14°C (248 ± 25°F) at the exit end during sampling. Because the actual temperature at the outlet of the probe is not usually monitored during sampling, probes constructed and calibrated according to the procedure in Reference 2 are considered acceptable. Either borosilicate or quartz-glass probe liners may be used for stack temperatures up to about 480°C (900°F). Quartz liners shall be used for temperatures between 480 and 900°C (900 and 1650°F). (The softening temperature for borosilicate is 820°C (1508°F), and for quartz 1500°C (2732°F).) Water-cooling of the stainless steel sheath will be necessary at temperatures approaching and exceeding 500°C.

4.1.3.3 Pitot tube. Type S, as described in Section 2.1 of Method 2 (Reference 1). The pitot tube shall be attached to the probe to allow constant monitoring of the stack-gas velocity. The impact (high-pressure) opening plane of the pitot tube shall be even with or above the nozzle entry plane (see Section 3.1.1 of Reference 2) during sampling. The Type S pitot tube assembly shall have a known coefficient, determined as outlined in Section 3.1.1 of Reference 2.

4.1.3.4 Differential pressure gauge. Inclined manometer or equivalent device as described in Section 2.2 of Method 2. One manometer shall be used for velocity-head (delta P) readings and the other for orifice differential pressure (delta H) readings.

4.1.3.5 Cyclone (optional), glass.

4.1.3.6 Filter holder. Borosilicate glass, with a Teflon frit filter support and a sealing gasket. The sealing gasket shall be constructed of Teflon or equivalent materials. The holder design shall provide a positive seal against leakage at any point along the filter circumference. The holder shall be attached immediately to the outlet of the cyclone.

4.1.3.7 Filter heating system. Any heating system capable of maintaining a temperature of 120 ± 14°C (248 ± 25°F) around the filter holder and cyclone during sampling. A temperature gauge capable of measuring temperature to within 3°C (5.4°F) shall be installed so that the temperature around the filter holder can be regulated and monitored during sampling.

4.1.3.8 Impinger train. The following system shall be used to determine the stack gas moisture content and to collect HCl and Cl_2: five or six impingers connected in series with leak-free ground glass fittings or any similar leak-free non-contaminating fittings. The first impinger shown in Figure 1 (knockout or condensate impinger) is optional and is recommended as a water knockout trap for use under test conditions which require such a trap. If used, this impinger should be constructed as described below for the alkaline impingers, but with a shortened stem, and should contain 50 ml of 0.05 M H_2SO_4. The following two impingers (acid impingers which each contain 100 ml of 0.05 M H_2SO_4) shall be of the Greenburg-Smith design with the standard tip (see Method 0010, Section 4). The next two impingers (alkaline impingers which each contain 100 mL of 0.1 M NaOH) and the last impinger (containing silica gel) shall be of the Greenburg-Smith design modified

by replacing the tip with a 1.3-cm (½-in.) I.D. glass tube extending about 1.3 cm (½ in.) from the bottom of the impinger (see Method 5, Section 4).

The condensate, acid, and alkaline impingers shall contain known quantities of the appropriate absorbing reagents. The last impinger shall contain a known weight of silica gel or equivalent desiccant.

4.1.3.9 Metering system. The necessary components are a vacuum gauge, leak-free pump, thermometers capable of measuring temperature to within 3°C (5.4°F), dry-gas meter capable of measuring volume to within 1%, an orifice meter (rate meter), and related equipment, as shown in Figure 1. At a minimum, the pump should be capable of 113 m^3/min (4 cfm) free flow, and the dry-gas meter should have a recording capacity of 0-28.3 m^3 (0-999.9 ft^3) with a resolution of 0.142 liters (0.005 ft^3). Other metering systems capable of maintaining sampling rates within 10% of isokineticity and of determining sample volumes to within 2% may be used. The metering system must be used in conjunction with a pitot tube to enable checks of isokinetic sampling rates.

4.1.3.10 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure to within 2.5 mm Hg (0.1 in. Hg). In many cases, the barometric reading may be obtained from a nearby National Weather Service station, in which case the station value (which is the absolute barometric pressure) is requested and an adjustment for elevation differences between the weather station and sampling point is applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30-m (100 ft) elevation increase (vice versa for elevation decrease).

4.1.3.11 Gas density determination equipment. Temperature sensor and pressure gauge (as described in Sections 2.3 and 2.4 of Method 2), and gas analyzer, if necessary (as described in Method 3, Reference 1). The temperature sensor ideally should be permanently attached to the pitot tube or sampling probe in a fixed configuration such that the tip of the sensor extends beyond the leading edge of the probe sheath and does not touch any metal. Alternatively, the sensor may be attached just prior to use in the field. Note, however, that if the temperature sensor is attached in the field, the sensor must be placed in an interference-free arrangement with respect to the Type S pitot tube openings (see Method 2, Figure 2-7). As a second alternative, if the stack gas is saturated, the stack temperature may be measured at a single point near the center of the stack.

4.1.3.12 Ascarite tube for conditioning ambient air. Tube tightly packed with approximately 150 g of fresh 8 to 20 mesh Ascarite II^R sodium hydroxide coated silica, or equivalent, to dry and remove acid gases from the ambient air used to remove moisture from the filter and optional cyclone. The inlet and outlet ends of the tube should be packed with at least 1 cm thickness of glass wool or filter material suitable to prevent escape of Ascarite II fines. Fit one end with flexible tubing, etc. to allow connection to probe nozzle.

4.2 Sample Recovery.

4.2.1 Probe liner. Probe and nozzle brushes; nylon (Teflon) bristle brushes with stainless steel wire handles are required. The probe brush shall have extensions of stainless steel, Teflon, or inert material at least as long as the probe. The brushes shall be properly sized and shaped to brush out the probe liner and the probe nozzle.

4.2.2 Wash bottles. Two. Polyethylene or glass, 500 mL or larger.

4.2.3 Glass sample storage containers. Glass, 500- or 1,000-mL. Screw-cap liners shall be Teflon and constructed so as to be leak-free. Narrow-mouth glass bottles have been found to exhibit less tendency toward leakage.

4.2.4 Petri dishes. Glass or plastic sealed around the circumference with Teflon tape, for storage and transport of filter samples.

4.2.5 Graduated cylinder and/or balances. To measure condensed water to the nearest 1 mL or 1 g. Graduated cylinders shall have subdivisions not >2 mL. Laboratory triple-beam balances capable of weighing to ± 0.5 g or better are required.

4.2.6 Plastic storage containers. Screw-cap polypropylene or polyethylene containers to store silica gel.

4.2.7 Funnel and rubber policeman. To aid in transfer of silica gel to container (not necessary if silica gel is weighed in field).

4.2.8 Funnels. Glass, to aid in sample recovery.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in the method refer to reagent grade water as defined in Chapter One unless otherwise specified. It is advisable to analyze a blank sample of this water prior to sampling, since the reagent blank values obtained during the field sample analysis must be less than 10 percent of the sample values.

5.3 Sulfuric acid (0.05 M), H_2SO_4. Used as the HCl absorbing reagent in the impinger train. To prepare 1 L, slowly add 2.80 mL of concentrated H_2SO_4 to about 900 mL of water while stirring, and adjust the final volume to 1-L using additional water. Shake well to mix the solution. It is advisable to analyze a blank sample of this reagent prior to sampling, since the reagent blank values obtained during the field sample analysis must be less than 10 percent of the sample values.

5.4 Sodium hydroxide (0.1 M), NaOH. Used as the Cl_2 absorbing reagent in the impinger train. To prepare 1 L, dissolve 4.00 g of solid NaOH in about 900 mL of water and adjust the final

volume to 1-L using additional water. Shake well to mix the solution. It is advisable to analyze a blank sample of this reagent prior to sampling, since the reagent blank values obtained during the field sample analysis must be less than 10 percent of the sample values.

5.5 Filter. Quartz-fiber or Teflon mat (e.g., Pallflex^{R} TX40HI45) filter, or equivalent.

5.6 Silica gel. Indicating type, 6-16 mesh. If previously used, dry at 175°C (350°F) for 2 hours before using. New silica gel may be used as received. Alternatively, other types of desiccants may be used if equivalence can be demonstrated.

5.7 Acetone. When using this train for determination of particulate emissions, reagent grade acetone, ≤ 0.001 percent residue, in glass bottles is required. Acetone from metal containers generally has a high residue blank and should not be used. Sometimes suppliers transfer acetone to glass bottles from metal containers; thus, acetone blanks shall be run prior to field use and only acetone with low blank values (≤ 0.001 percent) shall be used. In no case shall a blank value greater than 0.001 percent of the weight of acetone used be subtracted from the sample weight.

5.8 Crushed ice. Quantities ranging from 10-50 lb may be necessary during a sampling run, depending on ambient air temperature.

5.9 Screw-on connectors, Teflon sleeves on ground-glass joints, or other greaseless fittings should be used.

5.10 Sodium thiosulfate (0.5 M), $Na_2S_2O_3$. Used as the reducing agent added to the sodium hydroxide filled impingers to promote the reaction given in Section 2.0. Buy premixed reagent grade, as free of chloride as possible.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Sample collection is described in this method. The analytical procedures for HCl and Cl_2 are described in Method 9057 and for particulate matter in Method 0100.

6.2 Samples should be stored in clearly labeled, tightly sealed containers between sample recovery and analysis. They may be analyzed up to four weeks after collection.

7.0 PROCEDURE

7.1 Preparation for Field Test.

7.1.1 All sampling equipment shall be maintained and calibrated the procedures described in Section 3.4.2 of EPA's Quality Assurance Handbook, Volume III (Reference 2) and in Methods 1-5 (Reference 1).

7.1.2 Weigh several 200-300-g portions of silica gel in airtight containers to the nearest 0.5-g. Record on each container the total weight of the silica gel plus containers. As an alternative to preweighing the silica gel, it may instead be weighed directly in the impinger just prior to train assembly.

7.1.3 Check filters visually against light for irregularities and flaws or pinhole leaks. Label the shipping containers (glass or plastic Petri dishes) and keep the filters in these containers at all times except during sampling (and weighing for particulate analysis).

7.1.4 If a particulate determination will be conducted, desiccate the filters at 20 ± 5.6°C (68 ± 10°F) and ambient pressure for at least 24 h, and weigh at intervals of at least 6 h to a constant weight (i.e., <0.5-mg change from previous weighing), recording results to the nearest 0.1 mg. During each weighing, the filter must not be exposed for more than a 2-min period to the laboratory atmosphere and relative humidity above 50%. Alternatively, the filters may be oven-dried at 105°C (220°F) for 2-3 h, desiccated for 2 h, and weighed.

7.2 Preliminary Field Determinations.

7.2.1 Select the sampling site and the minimum number of sampling points according to Method 1. Determine the stack pressure, temperature, and range of velocity heads using Method 2. It is recommended that a leak-check of the pitot lines (see Method 2) be performed. Determine the stack-gas moisture content using Method 4 or its alternatives to establish estimates of isokinetic sampling rate settings. Determine the stack gas dry molecular weight, as described in Method 2, Section 3. If integrated Method 3 (Reference 1) sampling is used for molecular weight determination, the integrated bag sample shall be taken simultaneously with, and for the same total length of time as the sample run.

7.2.2 Select a nozzle size based on the range of velocity heads so that it is not necessary to change the nozzle size to maintain isokinetic sampling rates. During the run, do not change the nozzle. Ensure that the proper differential pressure gauge is chosen for the range of velocity heads encountered (see Section 2 of Method 2).

7.2.3 Select a suitable probe liner and probe length so that all traverse points can be sampled. For large stacks, to reduce the length of the probe, consider sampling from opposite sides of the stack.

7.2.4 The total sampling time should be two hours. Allocate the same time to all traverse points defined by Method 1. To avoid timekeeping errors, the length of time sampled at each traverse point should be an integer or an integer plus one-half min. Size the condensate impinger for the expected moisture catch or be prepared to empty it during the run.

7.3 Preparation of Sampling Train.

7.3.1 Add 50 mL of 0.05 M H_2SO_4 to the condensate impinger, if used. Place 100 mL of 0.05 M H_2SO_4 in each of the next two impingers. Place 100 mL of 0.1 M NaOH in each of the following two impingers. It is essential that the NaOH filled impingers be maintained strongly basic throughout the sampling run. In highly acid stack environments, this may require measures such as stronger base, more volume of basic solution, or changeout of impinger liquid during the run. When in doubt, the pH of the solution should be monitored frequently or continuously. Finally, transfer approximately 200-300 g of preweighed silica gel from its container to the last impinger. More silica gel may be used, but care should be taken to ensure that it is not entrained and carried out from the impinger

during sampling. Place the silica gel container in a clean place for later use in the sample recovery. Alternatively, the weight of the silica gel plus impinger may be determined to the nearest 0.5 g and recorded.

7.3.2 Using a tweezer or clean disposable surgical gloves, place a labeled (identified) filter (weighed, if particulate matter is to be determined) in the filter holder. Be sure that the filter is properly centered and the gasket properly placed to prevent the sample gas stream from circumventing the filter. Check the filter for tears after assembly is completed.

7.3.3 To use glass liners, install the selected nozzle using a Viton-A O-ring when stack temperatures are <260°C (500°F) and a woven glass fiber gasket when temperatures are higher. Other connecting systems utilizing Teflon ferrules may be used. Mark the probe with heat-resistant tape or by some other method to denote the proper distance into the stack or duct for each sampling point.

7.3.4 Set up the train as in Figure 1. Connect temperature sensors to the appropriate potentiometer/display unit. Check all temperature sensors at ambient temperature.

7.3.5 Place crushed ice around the impingers.

7.3.6 Turn on and set the filter and probe heating systems at the desired operating temperatures. Allow time for the temperatures to stabilize.

7.4 Leak-check Procedures.

7.4.1 Pretest leak-check. A pretest leak-check is recommended, but not required. If the tester opts to conduct the pretest leak-check, the following procedure shall be used.

7.4.1.1 If a Viton A O-ring or other leak-free connection is used in assembling the probe nozzle to the probe liner, leak-check the train at the sampling site by plugging the nozzle and pulling a 380-mm Hg (15-in. Hg) vacuum.

NOTE: A lower vacuum may be used, provided that it is not exceeded during the test.

7.4.1.2 If a woven glass fiber gasket is used, do not connect the probe to the train during the leak-check. Instead, leak-check the train by first plugging the inlet to the cyclone, if used, or the filter holder and pulling a 380-mm Hg (15-in. Hg) vacuum (see NOTE above). Then, connect the probe to the train and leak-check at about 25-mm Hg (1-in. Hg) vacuum; alternatively, leak-check the probe with the rest of the sampling train in one step at 380-mm Hg (15-in. Hg) vacuum. Leakage rates in excess of 4% of the average sampling rate or 0.00057 m^3/min (0.02 cfm), whichever is less, are unacceptable.

7.4.1.3 The following leak-check instructions for the sampling train may be helpful. Start the pump with bypass valve fully open and coarse adjust valve completely closed. Partially open the coarse adjust valve and slowly close the bypass valve until the desired vacuum is reached. Do not reverse direction of the

bypass valve; this will cause water to back up into the filter holder. If the desired vacuum is exceeded, either leak-check at this higher vacuum or end the leak-check, as shown below, and start over.

7.4.1.4 When the leak-check is completed, first slowly remove the plug from the inlet to the probe, cyclone, or filter holder and immediately turn off the vacuum pump. This prevents the liquid in the impingers from being forced backward into the filter holder and silica gel from being entrained backward into the fifth impinger.

7.4.2 Leak-checks during sample run. If, during the sampling run, a component (e.g., filter assembly or impinger) change becomes necessary or a port change is conducted, a leak-check shall be conducted immediately after the interruption of sampling and before the change is made. The leak-check shall be conducted according to the procedure outlined in Section 7.4.1, except that it shall be conducted at a vacuum greater than or equal to the maximum value recorded up to that point in the test. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable. If a higher leakage rate is obtained, the tester shall void the sampling run. Immediately after a component change or port change, and before sampling is reinitiated, another leak-check similar to a pre-test leak-check is recommended.

7.4.3 Post-test leak-check. A leak-check is mandatory at the conclusion of each sampling run. The leak-check shall be done using the same procedures as those with the pre-test leak-check, except that it shall be conducted at a vacuum greater than or equal to the maximum value reached during the sampling run. If the leakage rate is found to be no greater than 0.00057 m^3/min (0.02 cfm) or 4% of the average sampling rate (whichever is less), the results are acceptable. If a higher leakage rate is obtained, the tester shall void the sampling run.

7.5 Train Operation.

7.5.1 During the sampling run, maintain an isokinetic sampling rate to within 10% of true isokinetic. Maintain a temperature around the filter and (cyclone, if used) of 120 ± 14°C (248 ± 25°F).

7.5.2 For each run, record the data required on a data sheet such as the one shown in Figure 2. Be sure to record the initial dry gas meter reading. Record the dry gas meter readings at the beginning and end of each sampling time increment, when changes in flow rates are made before and after each leak-check, and when sampling is halted. Take other readings required by Figure 2 at least once at each sample point during each time increment and additional readings when significant changes (20% variation in velocity head readings) necessitate additional adjustments in flow rate. Level and zero the manometer. Because the manometer level and zero may drift due to vibrations and temperature changes, make periodic checks during the traverse.

7.5.3 Clean the stack access ports prior to the test run to eliminate the chance of sampling deposited material. To begin sampling, remove the nozzle cap, verify that the filter and probe heating systems are at the specified temperature, and verify that the pitot tube and probe are positioned properly. Position the nozzle at the first traverse point, with the tip pointing directly into the gas stream. Immediately start the pump and adjust the flow to

isokinetic conditions using a calculator or a nomograph. Nomographs are designed for use when the Type S pitot tube coefficient is 0.84 and the stack gas equivalent density (dry molecular weight) is equal to 29 ± 4. If the stack gas molecular weight and the pitot tube coefficient are outside the above ranges, do not use the nomographs unless appropriate steps are taken to compensate for the deviations (see Reference 3).

7.5.4 When the stack is under significant negative pressure (equivalent to the height of the impinger stem), take care to close the coarse adjust valve before inserting the probe into the stack, to prevent water from backing into the filter holder. If necessary, the pump may be turned on with the coarse adjust valve closed.

7.5.5 When the probe is in position, block off the openings around the probe and stack access port to prevent unrepresentative dilution of the gas stream.

7.5.6 Traverse the stack cross section, as required by Method 1, being careful not to bump the probe nozzle into the stack walls when sampling near the walls or when removing or inserting the probe through the access port, in order to minimize the chance of extracting deposited material.

7.5.7 During the test run, make periodic adjustments to keep the temperature around the filter holder (and cyclone, if used) at the proper level. Add more ice, and, if necessary, salt to maintain a temperature of <20°C (68°F) at the condenser/silica gel outlet. Also, periodically check the level and zero of the manometer.

7.5.8 If the pressure drop across the filter becomes too high, making isokinetic sampling difficult to maintain, it may be replaced in the midst of a sample run. Using another complete filter holder assembly is recommended, rather than attempting to change the filter itself. After a new filter assembly is installed, conduct a leak-check. If determined, the total particulate weight shall include the summation of all filter assembly catches.

7.5.9 If the condensate impinger becomes too full, it may be emptied, recharged with 50 mL of 0.05 M H_2SO_4, and replaced during the sample run. The condensate emptied must be saved and included in the measurement of the volume of moisture collected and included in the sample for analysis. The additional 50 mL of absorbing reagent must also be considered in calculating the moisture. After the impinger is reinstalled in the train, conduct a leak-check.

7.5.10 A single train shall be used for the entire sample run, except in cases where simultaneous sampling is required in two or more separate ducts or at two or more different locations within the same duct, or in cases where equipment failure necessitates a change of trains.

7.5.11 Note that when two or more trains are used, separate analyses of the particulate catch (if applicable) and the HCl and Cl_2 impinger catches from each train shall be performed, unless identical nozzle sizes were used on all trains. In that case, the particulate catch and the HCl and Cl_2 impinger catches from the individual trains may be combined, and a single particulate analysis and single HCl and Cl_2 analyses of the impinger contents may be performed.

7.5.12 At the end of the sample run, turn off the coarse adjust valve, remove the probe and nozzle from the stack, turn off the pump, record the final dry gas meter reading.

7.5.13 If there is any possibility that liquid has collected in the glass cyclone and/or on the filter, connect the Ascarite tube at the probe inlet and operate the train with the filter heating system at 120 ± 14°C (248 ± 25°F) at a low flow rate (e.g., $\Delta H = 1$) sufficient to vaporize the liquid and purge any HCl in the cyclone or on the filter and pull it through the train into the impingers. After 30 minutes, turn off the flow, remove the Ascarite tube, and examine the cyclone and filter for any visible moisture. If moisture is visible, repeat this step for 15 minutes. A 45 minute cyclone purge is not effective for removing greater than 25 mL of solution from the cyclone. Also, a 45 minute purge is more effective when the filter and probe temperatures are increased to 177°C. (See "Laboratory Evaluation of Method 0050 for Hydrogen Chloride").

7.5.14 Conduct a post-test leak-check. Also, leak-check the pitot lines as described in Method 2. The lines must pass this leak-check in order to validate the velocity-head data.

7.5.15 If the moisture value is available, calculate percent isokineticity (see Section 7.7.10) to determine whether the run was valid or another test run should be conducted.

7.6 Sample Recovery

7.6.1 Allow the probe to cool. When the probe can be handled safely, wipe off all the external surfaces of the tip of the probe nozzle and place a cap over the tip. Do not cap the probe tip tightly while the sampling train is cooling down because this will create a vacuum in the filter holder, drawing water from the impingers into the holder.

7.6.2 Before moving the sampling train to the cleanup site, remove the probe and cap the open outlet, being careful not to lose any condensate that might be present. Cap the filter or cyclone inlet. Remove the umbilical cord from the last impinger and cap the impinger. If a flexible line is used between the first impinger and the filter holder, disconnect it at the filter holder and let any condensed water drain into the first impinger. Cap the filter holder outlet and the impinger inlet. Ground glass stoppers, plastic caps, serum caps, Teflon tape, Parafilm^{R}, or aluminum foil may be used to close these openings.

7.6.3 Transfer the probe and filter/impinger assembly to the cleanup area. This area should be clean and protected from the weather to minimize sample contamination or loss.

7.6.4 Save portions of all washing solutions used for cleanup (acetone and reagent grade water) and the absorbing reagents (0.05 M H_2SO_4 and 0.1 M NaOH) as blanks. Transfer 200 mL of each solution directly from the wash bottle being used (rinse solutions) or the supply container (absorbing reagents) and place each in a separate, prelabeled glass sample container.

7.6.5 Inspect the train prior to and during disassembly and note any abnormal conditions.

7.6.6 Container No. 1 (filter catch for particulate determination). Carefully remove the filter from the filter holder and place it in its identified Petri dish container. Use one or more pair of tweezers to handle the filter. If it is necessary to fold the filter, ensure that the particulate cake is inside the fold. Carefully transfer to the Petri dish any particulate matter or filter fibers that adhere to the filter holder gasket, using a dry nylon bristle brush or sharp-edged blade, or both. Label the container and seal with Teflon tape around the circumference of the lid.

7.6.7 Container No. 2 (front-half rinse for particulate determination). Taking care that dust on the outside of the probe or other exterior surfaces does not get into the sample, quantitatively recover particulate matter or any condensate from the probe nozzle, probe fitting, probe liner, and front half of the filter holder by washing these components with acetone into a glass container. Retain an acetone blank and analyze with the samples.

7.6.8 Perform rinses as follows: carefully remove the probe nozzle and clean the inside surface by rinsing with acetone from a wash bottle and brushing with a nylon bristle brush. Brush until the rinse shows no visible particles; then make a final rinse of the inside surface with the acetone. Brush and rinse the inside parts of the Swagelok fitting with the acetone in a similar way until no visible particles remain.

7.6.9 Have two people rinse the probe liner with acetone by tilting and rotating the probe while squirting acetone into its upper end so that all inside surfaces will be wetted with solvent. Let the acetone drain from the lower end into the sample container. A glass funnel may be used to aid in transferring liquid washed to the container.

7.6.10 Follow the acetone rinse with a probe brush. Hold the probe in an inclined position and squirt acetone into the upper end while pushing the probe brush through the probe with a twisting action; place a sample container underneath the lower end of the probe and catch any acetone and particulate matter that is brushed from the probe. Run the brush through the probe three or more times until no visible particulate matter is carried out with the acetone or none remains in the probe liner on visual inspection. Rinse the brush with acetone and quantitatively collect these washings in the sample container. After the brushing, make a final acetone rinse of the probe as described above. Between sampling runs, keep brushes clean and protected from contamination.

7.6.11 Clean the inside of the front half of the filter holder and cyclone by rubbing the surfaces with a nylon bristle brush and rinsing with acetone. Rinse each surface three times, or more if needed, to remove visible particulate. Make a final rinse of the brush and filter holder. Carefully rinse out the glass cyclone and cyclone flask (if applicable). Brush and rinse any particulate material adhering to the inner surfaces of these components into the front-half rinse sample. After all rinses and particulate matter have been collected in the sample container, tighten the lid on the sample container so that acetone will not leak out when it is shipped to the laboratory. Mark the height of the fluid level to determine whether leakage occurs during transport. Label the container to identify its contents.

7.6.12 Container No. 3 (knockout and acid impinger catch for moisture and HCl determination). Disconnect the impingers. Measure the liquid in the acid and knockout impingers to within ± 1 mL by using a graduated cylinder or by weighing it to within ± 0.5 g by using a balance (if one is available). Record the volume or weight of liquid present. This

information is required to calculate the moisture content of the emission gas. Quantitatively transfer this liquid to a leak-free sample storage container. Rinse these impingers and the connecting glassware (and tubing, if used) with water, and add these rinses to the storage container. Seal the container, shake to mix, and label. The fluid level should be marked so that if any sample is lost during transport, a correction proportional to the lost volume can be applied. Retain rinse water and acidic absorbing solution blanks and analyze with the samples.

7.6.13 Container No. 4 (alkaline impinger catch for Cl_2 and moisture determination). Measure and record the liquid in the alkaline impingers as described in Section 7.6.12. Quantitatively transfer this liquid to a leak-free sample storage container. Rinse these two impingers and connecting glassware with water and add these rinses to the container. Add 2 mL or more of 0.5 M $Na_2S_2O_3$. to the sodium hydroxide (Cl_2) samples. It is necessary to add sufficient $Na_2S_2O_3$ to reduce the OCl^-, but too much thiosulfate may interfere with the ion chromatography analysis. The amount needed will vary with stack emission composition. In certain situations, it may be advantageous to add the $Na_2S_2O_3$ before sampling. Consult recent references for additional suggestions. Seal the container, shake to mix, and label; mark the fluid level. Retain alkaline absorbing solution blank and analyze with the samples.

7.6.14 Container No. 5 (silica gel for moisture determination). Note the color of the indicating silica gel to determine if it has been completely spent and make a notation of its condition. Transfer the silica gel from the last impinger to its original container and seal. A funnel may make it easier to pour the silica gel without spilling. A rubber policeman may be used as an aid in removing the silica gel from the impinger. It is not necessary to remove the small amount of dust particles that may adhere strongly to the impinger wall. Because the gain in weight is to be used for moisture calculations, do not use any water or other liquids to transfer the silica gel. If a balance is available in the field, weigh the container and its contents to 0.5 g or better.

7.6.15 Prior to shipment, recheck all sample containers to ensure that the caps are well secured. Seal the lids of all containers around the circumference with Teflon tape. Ship all liquid samples upright and all particulate filters with the particulate catch facing upward.

7.7 Calculations. Retain at least one extra decimal figure beyond those contained in the available data in intermediate calculations, and round off only the final answer appropriately.

7.7.1 Nomenclature.

A_n = Cross-sectional area of nozzle, m^2 (ft^2).

B_{ws} = Water vapor in the gas stream, proportion by volume.

C_a = Acetone blank residue concentration, mg/mg.

C_p = Type S pitot tube coefficient (nominally 0.84), dimensionless.

c_s = Concentration of particulate matter in stack gas, dry basis, corrected to standard conditions, g/dscm (g/dscf).

I = Percent of isokinetic sampling.

m_a = Mass of residue of acetone after evaporation, mg.

M_n = Total amount of particulate matter collected, mg.

M_d = Stack-gas dry molecular weight, g/g-mole (lb/lb-mole).

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).

P_{bar} = Barometric pressure at the sampling site, mm Hg (in. Hg).

P_s = Absolute stack-gas pressure, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

R = Ideal gas constant, 0.06236 mm Hg-m^3/K-g-mole (21.85 in. Hg-ft^3/^oR-lb-mole).

T_m = Absolute average dry-gas meter temperature (see Figure 2), K (^oR).

T_s = Absolute average stack-gas temperature (see Figure 2), K (^oR).

T_{std} = Standard absolute temperature, 293K (528^oR).

V_{lc} = Total volume of liquid collected in the impingers and silica gel, mL.

V_m = Volume of gas sample as measured by dry-gas meter, dscm (dscf).

$V_{m(std)}$ = Volume of gas sample measured by the dry-gas meter, corrected to standard conditions, dscm (dscf).

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).

V_s = Stack-gas velocity, calculated by Method 2, Equation 2-9, using data obtained from Method 5, m/sec (ft/sec).

W_a = Weight of residue in acetone wash, mg.

V_a = Volume of acetone blank, mL.

V_{aw} = Volume of acetone used in wash; mL.

Y = Dry-gas-meter calibration factor, dimensionless.

H = Average pressure differential across the orifice meter, mm H_2O (in. H_2O).

ρ_a = Density of acetone, mg/ml (see label on bottle).

ρ_w = Density of water, 0.9982 g/mL (0.002201 lb/mL).

θ = Total sampling time, min.

13.6 = Specific gravity of mercury.

60 = Sec/min.

100 = Conversion to percent.

7.7.2 Average dry gas meter temperature and average orifice pressure drop. See data sheet (Figure 2).

7.7.3 Dry gas volume. Correct the sample measured by the dry gas meter to standard conditions (20°C, 760 mm Hg [68°F, 29.92 in. Hg]) by using Equation 1:

$$V_{m(std)} = V_m Y \frac{T_{std}}{T_m} \frac{P_{bar} + \Delta H/13.6}{P_{std}} = K_1 V_m Y \frac{P_{bar} + H/13.6}{T_m} \quad (1)$$

where: K_1 = 0.3858 K/mm Hg for metric units, or
K_1 = 17.64°R/in. Hg for English units.

7.7.4 Volume of water vapor.

$$V_{w(std)} = V_{lc} \frac{\rho_w}{M_w} \frac{RT_{std}}{P_{std}} = K_2 V_{lc} \quad (2)$$

where: K_2 = 0.001333 m^3/mL for metric units, or
K_2 = 0.04707 ft^3/mL for English units.

7.7.5 Moisture content.

$$B_{ws} = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}} \quad (3)$$

NOTE: In saturated or water-droplet-laden gas streams, two calculations of the moisture content of the stack gas shall be made, one from the impinger analysis (Equation 3) and a second from the assumption of saturated conditions. The lower of the two values of B_w shall be considered correct. The procedure for determining the moisture content based upon assumption of saturated conditions is given in the Note to Section 1.2 of Method 4. For the purposes of this method, the average stack gas temperature from Figure 2 may be used to make this determination, provided that the accuracy of the in-stack temperature sensor is ± 1°C (2°F).

7.7.6 Acetone blank concentration. For particulate determination.

$$C_a = \frac{m_a}{V_a \rho_a} \quad (4)$$

7.7.7 Acetone wash blank. For particulate determination.

$$W_a = C_a \, V_{aw} \, \rho_a \quad (5)$$

7.7.8 Total particulate weight. Determine the total particulate catch from the sum of the weights obtained from Container Nos. 1 and 2 less the acetone blank (W_a).

7.7.9 Particulate concentration.

$$c_s = (0.001 \text{ g/mg})(m_n/V_{m(std)}) \quad (6)$$

7.7.10 Isokinetic variation.

7.7.10.1 Calculation from raw data.

$$I = \frac{100 \, T_s[K_3 V_{lc} + (V_m/T_m)(P_{bar} + \Delta H/13.6)]}{60 \theta V_s P_s A_n} \quad (7)$$

where: $K_3 = 0.003454$ mm Hg-m^3/mL-K for metric units, or
$K_3 = 0.002669$ in. Hg-ft^3/mL ^oR for English units.

7.7.10.2 Calculation for intermediate values.

$$I = \frac{T_s V_{m(std)} P_{std} 100}{T_{std} V_s \, \theta \, A_n P_s 60(1-B_{ws})} \quad (8)$$

$$= K_4 \frac{T_s V_{m(std)}}{P_s V_s A_n \, \theta \, (1-B_{ws})}$$

where: $K_4 = 4.320$ for metric units, or
$K_4 = 0.09450$ for English units.

7.7.11 Acceptable results. If 90% $\leq I \leq$ 110%, the results are acceptable.

7.7.12 Analytical calculation for total µg HCl per sample. Calculate as described below:

$$m_{HCl} = S \times V_s \times 36.46/35.45$$

where:

m_{HCl} = Mass of HCl in sample, µg
S = Analysis of sample, µg Cl^-/mL
V_s = Volume of filtered and diluted sample, mL
36.46 = Molecular weight of HCl, µg/µg-mole
35.45 = Molecular weight of Cl^-, µg/µg-mole

7.7.13 Analytical calculation for total µg Cl_2 per sample. Calculate as described below:

$$m_{Cl2} = S \times V_2$$

where:

V_2 = Volume of filtered and diluted sample, mL
S = Analysis of sample, µg Cl^-/mL
m_{Cl2} = Mass of Cl_2 in sample, µg

7.7.14 Concentration of HCl in the flue gas. Calculate as described below:

$$C = K \times m/V_{m(std)}$$

where:

C = Concentration of HCl or Cl_2, dry basis, mg/dscm,
$K = 10^{-3}$ mg/µg,
m = Mass of HCl or Cl_2 in sample, µg, and
$V_{m(std)}$ = Dry gas volume measured by the dry gas meter, corrected to standard conditions, dscm.

8.0 QUALITY CONTROL

8.1 Sampling. See EPA Manual 600/4-77-027b for Method 5 quality control.

8.2 Analysis. At the present time, a validated audit material does not exist for this method. Analytical quality control procedures are detailed in Method 9057.

8.3 Quality control check sample. Chloride solutions of reliably known concentrations are available for purchase from the National Institute of Standards and Technology (SRM 3182). The QC check sample should be prepared in the appropriate absorbing reagent at a concentration approximately equal to the mid range calibration standard. The quality control check sample should be injected in duplicate immediately after the calibration standards have been injected the first time.

The Cl^- value obtained for the check sample using the final calibration curve should be within 10 percent of the known value for the check sample.

9.0 METHOD PERFORMANCE

9.1 The in-stack limit for HCl for the method is approximately 0.02 mg/dscm of stack gas. The method has a negative bias below 20 ppm HCl (Reference 6).

9.2 It is preferable to include the cyclone in the sampling train to protect the filter from any moisture present. There is research in progress regarding the necessity of the cyclone at low moisture sources and the use of Ascarite II in the drying procedure (Section 7.5.12).

9.3 The lower detection limit of the analytical method is 0.1 ug of Cl^- per mL of sample solution. Samples with concentrations which exceed the linear range of the IC may be diluted.

9.4 The precision and bias for analysis of HCl using this analytical protocol have been measured in combination with the midget impinger HCl/Cl_2 train (Method 0051) for sample collection. The laboratory relative standard deviation is within 6.2 percent and 3.2 percent at HCl concentrations of 3.9 and 15.3 ppm. respectively. The method does not exhibit any bias for HCl when sampling at Cl_2 concentrations less than 50 ppm.

METHOD 0051

MIDGET IMPINGER HCl/Cl_2 EMISSION SAMPLING TRAIN

1.0 SCOPE AND APPLICATION

This method describes the collection of hydrogen chloride (HCl, CAS Registry Number 7647-01-0) and chlorine (Cl_2, CAS Registry Number 7782-50-5) in stack gas emission samples from hazardous waste incinerators and municipal waste combustors. The collected samples are analyzed using Method 9057. This method is designed to collect HCl/Cl_2 in their gaseous forms. Use of this method is limited to the sampling of relatively dry, particulate-free gas streams. Sources, such as those controlled by wet scrubbers, that emit acid particulate matter (e.g., HCl dissolved in water droplets) must be sampled using an isokinetic HCl/Cl_2 sampling train (see Method 0050). This method has potential for collection of all halogens and halogen acids, but has not been fully evaluated for that use. For analytical determination of additional halides, Method 9056 is used rather than Method 9057.

2.0 SUMMARY OF METHOD

An integrated gas sample is extracted from the stack and passes through a particulate filter, acidified water, and finally through an alkaline solution. The filter serves to remove particulate matter such as chloride salts which could potentially react and form the analyte in the absorbing solutions. In the acidified water absorbing solution, the HCl gas is solubilized and forms chloride ions (Cl^-) as follows:

$$HCl + H_2O = H_3O^+ + Cl^-$$

The Cl_2 gas present in the emissions has a very low solubility in acidified water and passes through to the alkaline absorbing solution where it undergoes hydrolysis to form a proton (H^+), Cl^-, and hypochlorous acid (HClO) as follows:

$$H_2O + Cl_2 = H^+ + Cl^- + HClO$$

The Cl^- ions in the separate solutions are measured by ion chromatography (Method 9057).

Sodium thiosulfate solution is added to the contents of the hydroxide filled impingers, in order to promote the following reaction.

$$S_2O_3^{-2} + 4OCl^- + 2OH^- = 2SO_4^{-2} + 4Cl^- + H_2O$$

Conversion of all the original Cl_2 to the stable Cl^- ion, and appropriate adjustment of the analysis calculations, removes the possibility of partial reduction of OCl^- to Cl^- and the resulting high bias to the results.

3.0 INTERFERENCES

Volatile materials which produce chloride ions upon dissolution during sampling are obvious interferences in the measurement of HCl. One interferant for HCl is diatomic chlorine (Cl_2) gas which disproportionates to HCl and hypochlorous acid (HClO) upon dissolution in water. Cl_2 gas exhibits

a low solubility in water, however, and the use of acidic rather than neutral or basic solutions for collection of hydrogen chloride gas greatly reduces the dissolution of any chlorine present. Sampling a 400 ppm HCl gas stream containing 50 ppm Cl_2 with this method does not cause a significant bias. Sampling a 220 ppm HCl gas stream containing 180 ppm Cl_2 results in a positive bias of 3.4 percent in the HCl measurement.

4.0 APPARATUS AND MATERIALS

4.1 Sampling Train. The sampling train is shown in Figure 1 and component parts are discussed below.

4.1.1 Probe. Borosilicate glass, approximately 3/8-in. (9-mm) inside diameter, with a heating system to prevent condensation. When the concentration of alkaline particulate matter in the emissions is high, a 3/8-in. (9-mm) inside diameter Teflon elbow should be attached to the inlet of the probe. A 1-in. (25-mm) length of Teflon tubing with a 3/8-in. (9-mm) inside diameter should be attached at the open end of the elbow to permit the opening of the probe to be turned away from the gas stream, thus reducing the amount of particulate entering the train. When high concentrations of particulate matter are not present, the Teflon elbow is unnecessary, and the probe inlet can be perpendicular to the gas stream. When sampling at locations where gas temperatures are greater than approximately 400°F, such as wet scrubber inlets, glass or quartz elbows must be used. In no case should a glass wool plug be used to remove particulate matter; use of such a filtering device could result in a bias in the data. Instead, a Teflon filter should be used as specified in Section 5.5.

4.1.2 Three-way stopcock. A borosilicate, three-way glass stopcock with a heating system to prevent condensation. The heated stopcock should connect directly to the outlet of the probe and filter assembly and the inlet of the first impinger. The heating system should be capable of preventing condensation up to the inlet of the first impinger. Silicone grease may be used, if necessary, to prevent leakage.

4.1.3 Impingers. Five 30-ml midget impingers with leak-free glass connectors. For sampling at high moisture sources or for extended sampling times greater than one hour, a midget impinger with a shortened stem (such that the gas sample does not bubble through the collected condensate) should be used in front of the first impinger.

4.1.4 Mae West impinger or drying tube. Mae West design impinger (or drying tube, if a moisture determination is not to be conducted) filled with silica gel, or equivalent, to dry the gas sample and to protect the dry gas meter and pump.

4.1.5 Sample line. Leak-free, with compatible fittings to connect the last impinger to the needle valve.

4.1.6 Barometer. Mercury, aneroid, or other barometer capable of measuring atmospheric pressure within 2.5 mm Hg (0.1 in Hg). In many cases, the barometric reading may be obtained from a nearby National Weather Service station, in which case the station value (which is the absolute barometric pressure) shall be requested and an adjustment for the elevation differences between the weather station and sampling point shall be applied at a rate of minus 2.5 mm Hg (0.1 in. Hg) per 30 m (100 ft) elevation increase or vice versa for elevation decrease.

4.1.7 Purge pump, purge line, drying tube, needle valve, and rate meter. Pump capable of purging sample probe at 2 liters/min. with drying tube, filled with silica gel or equivalent, to protect pump, and a rate meter, 0 to 5 liters/min.

4.1.8 Metering system. The following items comprise the metering system which is identical to that used for EPA Method 6 (see Reference 5).

4.1.8.1 Valve. Needle valve, to regulate sample gas flow rate.

4.1.8.2 Pump. Leak-free diaphragm pump, or equivalent, to pull gas through train. Install a small surge tank between the pump and the rate meter to eliminate the pulsation effect of the diaphragm pump on the rotameter.

4.1.8.3 Rate meter. Rotameter, or equivalent, capable of measuring flow rate to within 2 percent of selected flow rate of 2 liters/min.

4.1.8.4 Volume meter. Dry gas meter, sufficiently accurate to measure the sample volume within 2 percent, calibrated at the selected flow rate and conditions encountered during sampling, and equipped with a temperature gauge (dial thermometer or equivalent) capable of measuring temperature to within 3°C (5.4°F).

4.1.8.5 Vacuum gauge. At least 760 mm Hg (30 in. Hg) gauge to be used for leak check of the sampling train.

4.1.9 Water Bath: To minimize loss of absorbing solution

4.2 Sample Recovery.

4.2.1 Wash bottles. Polyethylene or glass, 500 ml or larger, two.

4.2.2 Storage bottles. Glass, with Teflon-lined lids, 100 ml, to store impinger samples (two per sampling run).

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. All references to water in the method refer to reagent water as defined in Chapter One unless otherwise specified. It is advisable to analyze a blank sample of this reagent prior to sampling, since the reagent blank value obtained during the field sample analysis must be less than 10 percent of the sample values.

5.3 Sulfuric acid (0.05 M), H_2SO_4. Used as the HCl absorbing reagent. To prepare 100 mL, slowly add 0.28 mL of concentrated H_2SO_4 to about 90 mL of water while stirring, and adjust the final volume to 100 mL using additional water. Shake well to mix the solution. It is advisable to

analyze a blank sample of this reagent prior to sampling, since the reagent blank value obtained during the field sample analysis must be less than 10 percent of the sample values.

5.4 Sodium hydroxide (0.1 M), NaOH. Used as the Cl_2 absorbing reagent. To prepare 100 mL, dissolve 0.40 g of solid NaOH in about 90 mL of water and adjust the final volume to 100 mL using additional water. Shake well to mix the solution. It is advisable to analyze a blank sample of this reagent prior to sampling, since the reagent blank value obtained during the field sample analysis must be less than 10 percent of the sample value.

5.5 Filter. Teflon mat Pallflex® TX40HI75 or equivalent. Locate in a glass, quartz, or Teflon filter holder with a Teflon filter support in a filter box heated to 250°F.

5.6 Sodium thiosulfate (0.5 M), $Na_2S_2O_3$. Used as the reducing agent added to the sodium hydroxide filled impingers to promote the reaction given in Section 2.0. Buy premixed reagent grade, as free of chloride as possible.

5.7 Silica gel. Indicating type, 6- to 16-mesh. If the silica gel has been used previously, dry at 175°C (350°F) for 2 hours. New silica gel may be used as received. Alternatively, other types of desiccants (equivalent or better) may be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Sample collection is described in this method. The analytical procedures are described in Method 9057.

6.2 Samples should be stored in clearly labeled, tightly sealed containers between sample recovery and analysis. They may be analyzed up to four weeks after collection.

7.0 PROCEDURE

7.1 Calibration. Section 3.5.2 of EPA's Quality Assurance Handbook Volume III (Reference 4) may be used as a guide for these operations.

7.1.1 Dry Gas Metering System.

7.1.1.1 Initial calibration. Before its initial use in the field, first leak check the metering system (sample line, drying tube, if used, vacuum gauge, needle valve, pump, rate meter, and dry gas meter) as follows: plug the inlet end of the sampling line, pull a vacuum of 250 mm (10 in.) Hg, plug off the outlet of the dry gas meter, and turn off the pump. The vacuum should remain stable for 30 seconds. Carefully release the vacuum from the system by slowly removing the plug from the sample line inlet. Remove the sampling line (and drying tube, if applicable), and connect the dry gas metering system to a appropriately sized wet test meter (e.g., 1 liter per revolution). Make three independent calibration runs, using at least five revolutions of the dry gas meter per run. Calculate the calibration factor, Y (wet test meter calibration volume divided by the dry gas meter volume, with both volumes adjusted to the same reference temperature and pressure), for each run, and average the results. If any Y value deviates by more than 2 percent from the average, the

metering system is unacceptable for use. Otherwise, use the average as the calibration factor for subsequent test runs.

7.1.1.2 Post-test calibration check. After each field test series, conduct a calibration check as in Section 7.1.1.1 above, except for the following variations: (a) the leak check is not to be conducted, (b) three or more revolutions of the dry gas meter may be used, (c) only two independent runs need to be made. If the calibration factor does no deviate by more than 5 percent from the initial calibration factor (determined in Section 7.1.1.1), the dry gas meter volumes obtained during the test series are acceptable. If the calibration factor deviates by more than 5 percent, recalibrate the metering system as Section 7.1.1.1, and for the calculations, use the calibration factor (initial or recalibration) that yields the lower gas volume for each test run.

7.1.2 Thermometer(s). Prior to each field test, calibrate against mercury-in-glass thermometers at ambient temperature. If the thermometer being calibrated reads within 2°C (2.6°F) of the mercury-in-glass thermometer, it is acceptable. If not, adjust the thermometer or use an appropriate correction factor.

7.1.3 Rate meter. The rate meter should be cleaned and maintained according to the manufacturer's instructions.

7.1.4 Barometer. Prior to each field test, calibrate against a mercury barometer. The field barometer should agree within 0.1 in. Hg with the mercury barometer. If it does not, the field barometer should be adjusted.

7.2 Sampling.

7.2.1 Preparation of collection train. Prepare the sampling train as follows: The first or knockout impinger should have a shortened stem and be left empty to condense moisture in the gas stream. The next two midget impingers should each be filled with 15 mL of 0.05 M H_2SO_4. The fourth and fifth impingers should each be filled with 15 mL of 0.1 M NaOH. It is essential that the NaOH filled impingers be maintained strongly basic throughout the sampling run. In highly acid stack environments, this may require measures such as stronger base, more volume of basic solution, or changeout of impinger liquid during the run. When in doubt the pH of the solution should be monitored frequently or continuously. Place a fresh charge of silica gel, or equivalent, in the Mae West impinger (or the drying tube). Connect the impingers in series with the knockout impinger first, followed by the two impingers containing the acidified reagent and two impingers containing the alkaline reagent, and the Mae West impinger containing the silica gel. If the moisture will be determined, weigh the impinger assembly to the nearest $\pm$ 0.5 g and record the weight.

7.2.2 Leak check procedures. Leak check the probe and three-way stopcock prior to inserting the probe into the stack. Connect the stopcock to the outlet of the probe, and connect the sample line to the needle valve. Plug the probe inlet, turn on the sample pump, and pull a vacuum of at least 250 mm Hg (10 in. Hg). Turn off the needle valve, and note the vacuum gauge reading. The vacuum should remain stable for at least 30 seconds. Place the probe in the stack at the sampling location, and adjust the filter heating system to 121°C (250°F) and the probe and stopcock heating systems to a temperature sufficient to

prevent water condensation. Connect the first impinger to the stopcock, and connect the sample line to the last impinger and the needle valve. Upon completion of a sampling run, remove the probe from the stack and leak check as described above. If a leak has occurred, the sampling run must be voided. Alternatively, the portion of the train behind the probe may be leak checked between multiple runs at the same site as follows: Close the stopcock to the first impinger, and turn on the sample pump. Pull a vacuum of at least 250 mm Hg (10 in. Hg), turn off the needle valve, and note the vacuum gauge reading. The vacuum should remain stable for at least 30 seconds. Release the vacuum on the impinger train by turning the stopcock to the vent position to permit ambient air to enter. If this procedure is used, the full train leak check described above must be conducted following the final run and all preceding sampling runs voided if a leak has occurred.

7.2.3 Purge procedures. Immediately prior to sampling, connect the purge line to the stopcock and turn the stopcock to permit the purge pump to purge the probe (see Figure 1A). Turn on the purge pump, and adjust the purge rate to 2 liters/min. Purge for at least 5 minutes prior to sampling.

7.2.4 Sample collection. Turn on sample pump, pull a slight vacuum of approximately 25 mm Hg (1 in. Hg) on the impinger train, and turn the stopcock to permit stack gas to be pulled through the impinger train (see Figure 1C). Adjust the sampling rate to 2 liters/min. as indicated by the rate meter, and maintain this rate within 10 percent during the entire sampling run. Take readings of the dry gas meter, the dry gas meter temperature, rate meter, and vacuum gauge at least once every five minutes during the run. A sampling time of one hour is recommended. However, if the expected condensate catch for this sampling run duration will exceed the capacity of the sampling train, (1) a larger knockout impinger may be used or (2) two sequential half-hour runs may be conducted. At the conclusion of the sampling run, remove the train from the stack, cool, and perform a leak check as described in Section 7.2.2.

7.3 Sample recovery. Following sampling, disconnect the impinger train from the remaining sampling equipment at the inlet to the knockout impinger and the outlet to the last impinger. If performing a moisture determination, wipe off any moisture on the outside of the train; weigh the train to the nearest 0.5 g and record the weight. Then disconnect the impingers from each other. Quantitatively transfer the contents of the first three impingers (the knockout impinger and the two 0.05 M H_2SO_4 impingers) to a leak-free storage bottle. Add the water rinses of each of these impingers and connecting glassware to the storage bottle. The contents of the impingers and connecting glassware from the second set of impingers (containing the 0.1 M NaOH) should be recovered in a similar manner if a Cl_2 analysis is desired. Add 2 mL or more of 0.5 M $Na_2S_2O_3$. to the sodium hydroxide (Cl_2) samples. It is necessary to add sufficient $Na_2S_2O_3$ to reduce the OCl^-, but too much thiosulfate may interfere with the ion chromatography analysis. The amount needed will vary with stack emission composition. In certain situations, it may be advantageous to add the $Na_2S_2O_3$ before sampling. Consult recent references for additional suggestions. The sample bottle should be sealed, shaken to mix, and labeled; the fluid level should be marked so that if any sample is lost during transport, a correction proportional to the lost volume can be applied. Save portions of the 0.05 M H_2SO_4 and 0.1 M NaOH used as impinger reagents as reagent blanks. Take 50 ml of each and place in separate leak-free storage bottles. Label and mark the fluid levels as previously described.

7.4 Calculations. Retain at least one extra decimal figure beyond those contained in the available data in intermediate calculations, and round off only the final answer appropriately.

7.4.1 Nomenclature.

B_{ws} = Water vapor in the gas stream, proportion by volume.

M_w = Molecular weight of water, 18.0 g/g-mole (18.0 lb/lb-mole).

P_{bar} = Barometric pressure at the exit orifice of the dry gas meter, mm Hg (in. Hg).

P_{std} = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).

R = Ideal gas constant, 0.06236 mm Hg-m^3/K-g-mole (21.85 in. Hg-ft^3/°R-lb-mole).

T_m = Average dry gas meter absolute temperature, K (°R).

T_{std} = Standard absolute temperature, 293K (528°R).

V_{lc} = Total volume of liquid collected in impingers and silica gel, mL (equivalent to the difference in weight of the impinger train before and after sampling, 1 mg = 1 mL).

V_m = Dry gas volume as measured by the dry gas meter, dcm (dcf).

$V_{m(std)}$ = Dry gas volume measured by the dry gas meter, corrected to standard conditions, dscm (dscf).

$V_{w(std)}$ = Volume of water vapor in the gas sample, corrected to standard conditions, scm (scf).

Y = Dry gas meter calibration factor.

ρ_w = Density of water, 0.9982 g/mL (0.002201 lb/mL).

7.4.2 Sample volume, dry basis, corrected to standard conditions. Calculate as described below:

$$V_{m(std)} = V_m Y \frac{T_{std}}{T^m} \frac{P_{bar}}{P_{std}} = K_1 Y \frac{V_m P_{bar}}{T_m} \quad (1)$$

where:

K_1 = 0.3858K/mm Hg for metric units.
= 17.64°R/in. Hg for English units.

7.4.3 Volume of water vapor.

$$V_{w(std)} = V_{lc} \frac{\rho_w}{M_w} \frac{RT_{std}}{P_{std}} = K_2 V_{lc} \quad (2)$$

where:

K_2 = 0.0013333 m^3/mL for metric units.
= 0.04707 ft^3/mL for English units.

7.4.4 Moisture content.

$$B_{ws} = \frac{V_{w(std)}}{V_{m(std)} + V_{w(std)}} \quad (3)$$

7.4.5 Analytical calculation of total ug HCl per sample. Calculate as described below:

$$m_{HCl} = S \times V_s \times 36.46/35.45$$

where:

m_{HCl} = Mass of HCl in sample, µg
S = Analysis of sample, µg Cl^-/mL
V_s = Volume of filtered and diluted sample, mL
36.46 = Molecular weight of HCl, µg/µg-mole
35.45 = Molecular weight of Cl^-, µg/µg-mole

7.4.6 Analytical calculation of total µg Cl_2 per sample. Calculate as described below:

$$m_{Cl2} = S \times V_2$$

where:

V_2 = Volume of filtered and diluted sample, mL
S = Analysis of sample, µg Cl^-/mL
m_{Cl2} = Mass of Cl_2 in sample, µg

7.4.7 Concentration of HCl in the flue gas. Calculate as described below:

$C = K \times m/V_{m(std)}$

where: C = Concentration of HCl or Cl_2, dry basis, mg/dscm,
K = 10^{-3} mg/µg,
m = Mass of HCl or Cl_2 in sample, µg, and
$V_{m(std)}$ = Dry gas volume measured by the dry gas meter, corrected to standard conditions, dscm.

8.0 QUALITY CONTROL

8.1 At the present time, a validated audit material does not exist for this method. Analytical quality control procedures are detailed in Method 9057.

8.2 Quality control check sample. Chloride solutions of reliably known concentrations are available for purchase from the National Bureau of Standards (SRM 3182). The QC check sample should be prepared in the appropriate absorbing reagent at a concentration approximately equal to the mid range calibration standard. The quality control check sample should be injected in duplicate immediately after the calibration standards have been injected the first time. The Cl^- value obtained for the check sample using the final calibration curve should be within 10 percent of the known value for the check sample.

9.0 METHOD PERFORMANCE

9.1 The in-stack limit for HCl for the method is approximately 0.08 mg/dscm of stack gas for a 1-hour sample.

9.2 The precision and bias for measurement of HCl using this sampling protocol combined with the analytical protocol, Method 9057, have been determined. The laboratory relative standard deviation is within 6.2 percent and 3.2 percent at HCl concentrations of 3.9 and 15.3 ppm, respectively. The method does not exhibit any bias for HCl when sampling at Cl_2 concentrations less than 50 ppm.

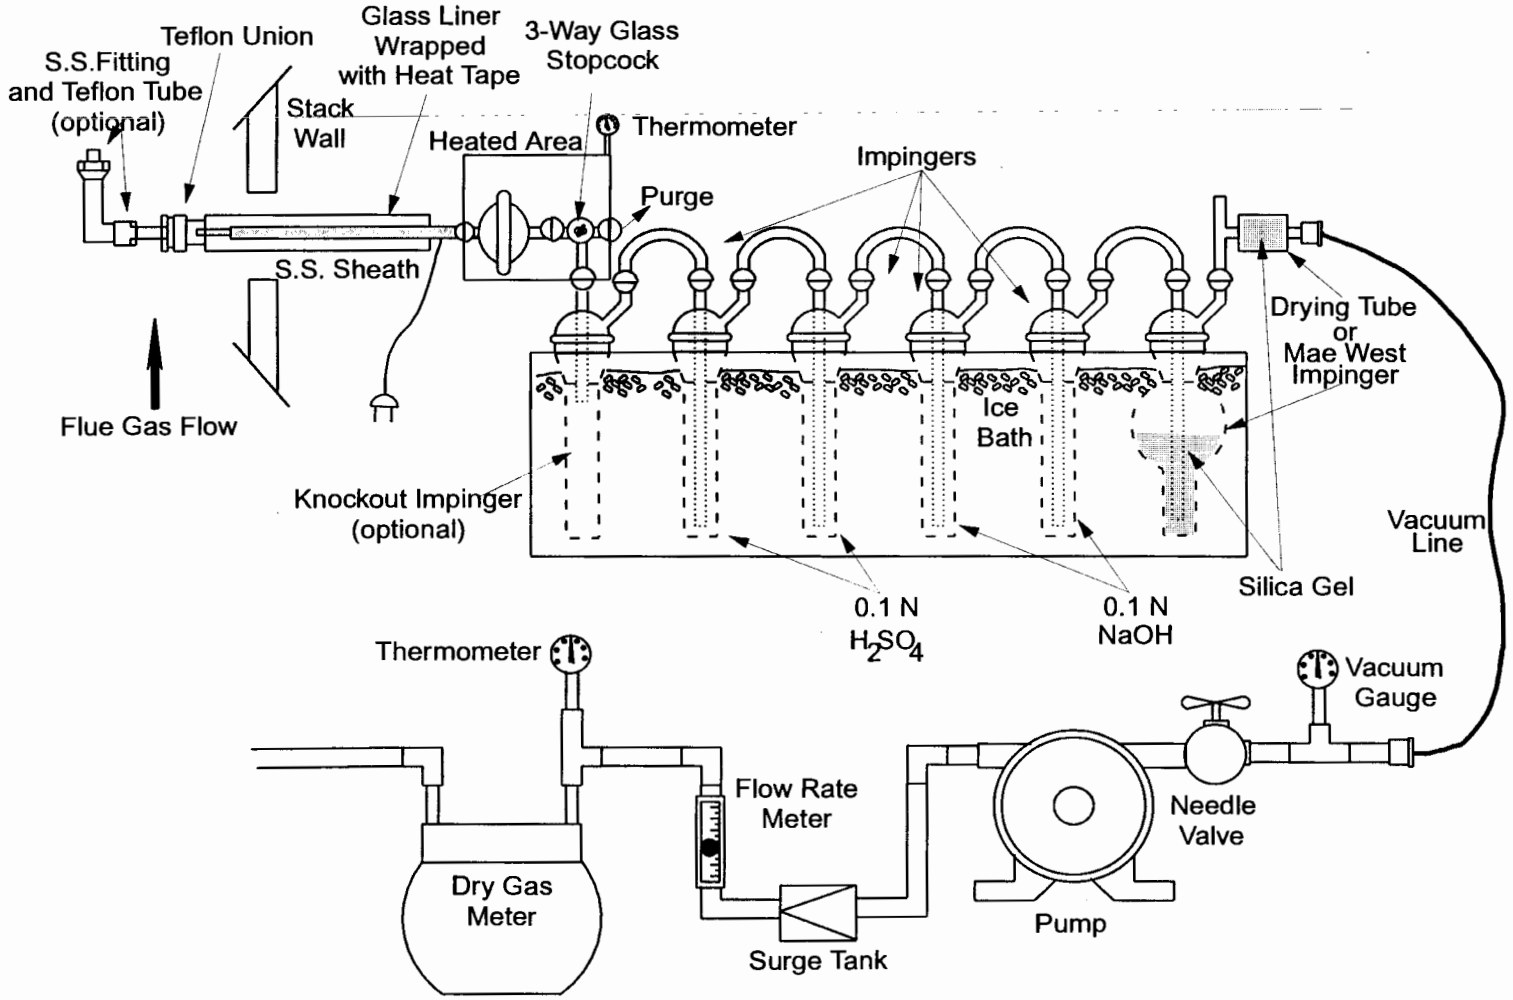

FIGURE 1. METHOD 0051 SAMPLING TRAIN

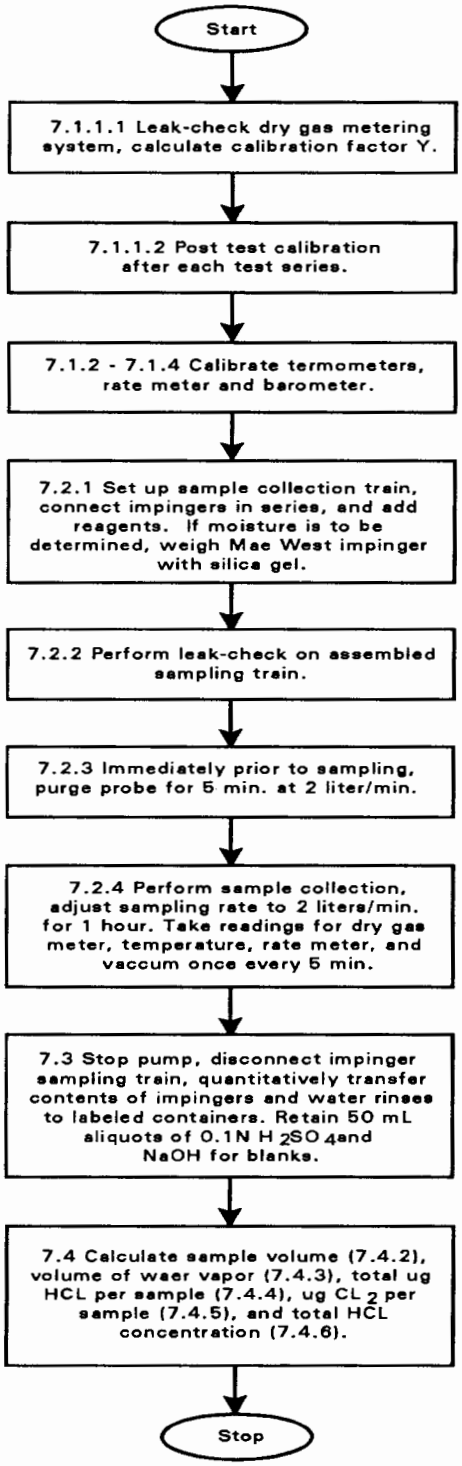
METHOD 0051

MIDGET IMPINGER HCl/Cl_2 EMISSION SAMPLING TRAIN



METHOD 0060

DETERMINATION OF METALS IN STACK EMISSIONS

1.0 SCOPE AND APPLICATION

1.1 This method is used to determine the concentration of metals in stack emissions from hazardous waste incinerators and similar combustion processes. Using the detection limits shown, the following parameters can be determined by this method:

TABLE 1. ESTIMATED IDLS FOR METALS DETERMINED BY METHOD 0060

Analyte	ICP-AES[a] µg/L	Flame AA[b] µg/L	GFAA[c] µg/L	CVAA[d] µg/L
Antimony (Sb)	40[e]	200[e]	3[e]	
Arsenic (As)	60	2[f]	1	
Barium (Ba)	2	100		
Beryllium (Be)	0.3	5	0.2	
Cadmium (Cd)	4	5	0.1	
Total chromium (Cr)	7	50	1	
Cobalt (Co)	7	50	1	
Copper (Cu)	6	20		
Lead (Pb)	50	100	1	
Manganese (Mn)	2	10		
Mercury (Hg)				0.2
Nickel (Ni)	20	40		
Phosphorus (P)	60			
Selenium (Se)	80	2[f]	2	
Silver (Ag)	7	10		
Thallium (Tl)	40	100	1	
Zinc (Zn)	2	5		

a Estimated IDLs by ICP-AES, Method 6010.
b Estimated IDLs by direct aspiration Flame AA, Method 7000.
c Estimated IDLs by Graphite Furnace AA, Method 7000.
d Estimated IDL by Cold Vapor AA, Method 7470.
e Detection limit for Sb may be higher depending on digestion used.
f Estimated IDLs for As and Se by Hydride AA, Method 7000.

1.2 This method may also be used for the determination of particulate emissions following the additional procedures described in Section 7.1.5.2.

1.3 For the analyses described in this methodology and for similar analyses, the response for Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) is linear over several

orders of magnitude. Samples containing metal concentrations in the micrograms per liter (µg/L) to milligrams per liter (mg/L) range in the final analytical solution can be analyzed using this technique. Samples containing greater than approximately 50 mg/L of chromium, lead, or arsenic should be diluted to that level or lower for final analysis. Samples containing greater than approximately 20 mg/L of cadmium should be diluted to that level before analysis.

1.4 The actual method detection limits are sample dependent and may vary as the sample matrix affects the limits. Method detection limits for antimony can also be dependent on the digestion method used and may be considerably higher than the estimated detection limits. Method detection limits for all analytes may differ from the estimated detection limits when hydrofluoric acid digestion is used. For more information on MDLs, refer to Chapter One.

1.5 The complexity of this methodology is such that to obtain reliable results, the testers (including analysts) should be experienced and as knowledgeable as required in source sampling, in handling and preparing (including mixing) reagents as discussed, and in using adequate safety procedures and protective equipment. The experience and knowledge should assure adequacy as described above in all of the source emission determination activities including planning of the desired detection limits.

2.0 SUMMARY

2.1 The stack sample is withdrawn isokinetically from the source. Particulate emissions are collected in the probe and on a heated filter and gaseous emissions are collected in a series of chilled impingers as shown in Figure 1 and described in Section 4.1.6. Two impingers are empty, two impingers contain an aqueous solution of dilute nitric acid combined with dilute hydrogen peroxide, two other impingers contain acidic potassium permanganate solution, and the last impinger contains a desiccant.

2.2 Sampling train components are recovered and digested in separate front-half and back-half fractions. Materials collected in the sampling train are acid digested to dissolve inorganics and to remove organic constituents that may create analytical interferences. Acid digestion is performed by using either digestion techniques of this manual, or the Method 29 (Ref. 3) procedures.

2.3 The nitric acid and hydrogen peroxide impinger solution, the hydrochloric acid rinse solution, the acidic potassium permanganate impinger solution, and the probe rinse and digested filter solutions are analyzed for mercury by Cold Vapor Atomic Absorption Spectrometry (CVAA). All of the sampling train catches, except for the permanganate solution, hydrochloric acid rinse solutions, and reagent water used to recover Hg, may be analyzed for target metals as presented in Table 1 by Inductively Coupled Plasma - Atomic Emission Spectrometry (ICP-AES) or Flame Atomic Absorption Spectrometry (FLAA). Similarly, Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) may be used for analysis of Sb, As, Ba, Be, Cd, Cr, Co, Cu, Pb, Mn, Ni, As, Tl and Zn. If antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, selenium, and thallium require greater analytical sensitivity than can be obtained by ICP-AES, then Graphite Furnace Atomic Absorption Spectrometry (GFAA) is used for the analysis. Additionally, if desired, the tester may use FLAA for analyses of all metals if the resulting in-stack method detection limits meet the goal of the testing program.

2.4 For convenience, aliquots of each digested sample Fraction 1A, as described in Section 7.2.3.2, plus Fraction 2A, as described in Section 7.2.4, can be combined for a single

analytical determination, proportionally with respect to the original Fractions 1A and 2A. Fraction 1A is normally diluted to 300 mL following digestion prior to analysis and the concentrated Fraction 2A is normally diluted to 150 mL following digestion and prior to analysis.

2.5 The efficiency of the analytical procedure is quantified by the analysis of spiked quality control samples containing each of the target metals and/or other quality assurance measures as described in Section 8.0 of this method including actual sample matrix effects checks.

3.0 INTERFERENCES

3.1 Refer to the appropriate determinative method for instructions on minimization of interferences.

4.0 APPARATUS AND MATERIALS

4.1 Sampling train - A schematic of the sampling train is shown in Figure 1. It is similar to the Method 5 (Ref. 3) train. The sampling train consists of the following components.

4.1.1 Probe nozzle (probe tip) and borosilicate or quartz glass probe liner - Same as Method 5, except that glass nozzles are required unless an alternate probe tip prevents the possibility of contamination or interference of the sample with its materials of construction. If a probe tip other than glass is used, no correction of the stack sample test results can be made because of the effect on the results by the probe tip.

4.1.2 Pitot tube and differential pressure gauge - Same as Method 2 (Ref. 3).

4.1.3 Filters - Quartz fiber or glass fiber filters without organic binders shall be used. The filters shall contain less than 1.3 µg/in.^{2} of each of the metals to be measured. Analytical results provided by filter manufacturers are acceptable. However, if no such results are available, filter blanks must be analyzed for each target metal prior to emission testing. The filters should exhibit at least 99.95 percent efficiency (<0.05 percent penetration) on 0.3 micron dioctyl phthalate smoke particles. The filter efficiency test should be conducted in accordance with ASTM Standard Method D2986-71 (Reference 4). For particulate determination in sources containing SO_2 or SO_3, the filter material must be of a type that is unreactive to SO_2 or SO_3, as described Method 5. Quartz fiber filters that meet these requirements are recommended.

4.1.4 Filter holder - Glass, same as Method 5, except that a Teflon filter support or other non-metallic, non-contaminating support must be used to replace the glass frit.

4.1.5 Filter heating system - Same as Method 5.

4.1.6 Condenser

4.1.6.1 The following system shall be used for the condensation and collection of gaseous metals and for determining the moisture content of the stack gas. The condensing system should consist of three to seven impingers connected in series with leak-free ground glass fittings or other leak-free, non-contaminating fittings. Teflon impingers of substantially the same shape, size and function

compared to the glass impingers and connected with leak-free non-contaminating fittings may be used: - additionally, the distance from the bottom of the gas conduit stem of the Teflon impinger assembly to the bottom of the portion of the impinger assembly which holds the aqueous acidic solutions must meet the same distance requirements as the glass impingers. The first impinger is optional and is recommended as a moisture knockout trap for use during test conditions which require such a trap. The first impinger shall be empty. The second and third impingers shall contain known quantities of a nitric acid/hydrogen peroxide solution (Section 5.8). The fourth shall be empty. The fifth and sixth impingers shall contain a known quantity of acidic potassium permanganate solution (Section 5.12), and the last impinger shall contain a known quantity of silica gel or equivalent desiccant. A thermometer capable of measuring to within 1°C (2°F) shall be placed at the outlet of the last impinger.

4.1.6.2 The first impinger shall be appropriately sized for a potentially large moisture catch and constructed generally as described for the first impinger in Method 5. The second impinger (or the first HNO_3/H_2O_2 impinger) shall also be as described for the first impinger in Method 5. The third impinger (or, in any case, the impinger used as the second HNO_3/H_2O_2 impinger) shall be the same as the Greenburg-Smith impinger with the standard tip described as the second impinger in Method 5. All other impingers used in the metals train are the same as the first HNO_3/H_2O_2 impinger.

4.1.6.3 Based on the specific source sampling conditions, the use of an empty first impinger can be eliminated if the moisture to be collected in the impingers will be less than approximately 100 mL. When the moisture knockout impinger is not needed, it is removed from the train and the other impingers remain the same. If mercury analysis is not to be performed, the potassium permanganate impingers and the empty impinger preceding them are removed.

4.1.7 Metering system, barometer, and gas density determination equipment - Same as Method 5.

4.1.8 Teflon tape - For capping openings and sealing connections, if necessary, on the sampling train.

4.2 Sample recovery. Same as Method 5, with the following exceptions and additions:

4.2.1 Non-metallic probe-liner and probe-nozzle brushes or swabs - For quantitative recovery of materials collected in the front half of the sampling train. Description of acceptable all-Teflon component brushes or swabs to be included in EPA's Emission Measurement Technical Information Center (EMTIC) files.

4.2.2 Sample storage containers - Glass bottles, 1000 mL and 500 mL, with Teflon-lined caps which are non-reactive to oxidizing solutions, shall be used for samples and blanks containing $KMnO_4$. Polyethylene bottles may be used for other sample types.

4.2.3 Polypropylene tweezers and/or plastic gloves - For recovery of the filter from the sampling train filter holder.

4.3 Sample preparation and analysis equipment.

4.3.1 Refer to the appropriate preparation and analytical techniques for the proper apparatus and materials. Refer to Section 7.2 for a description of preparation techniques.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Otherwise use the best available grade.

5.2 Reagent Water. Refer to Chapter One for a definition of reagent water. Analyze the water for all target metals prior to field use. All target metals should be less than the MDL.

5.3 Nitric acid, concentrated - Baker Instra-analyzed or equivalent.

5.4 Nitric acid (0.1 M) - Add, with stirring, 6.3 mL of concentrated HNO_3 to a flask containing approximately 900 mL of water. Dilute to 1000 mL with water. Mix well. The reagent shall contain less than 2 µg/L of each target metal.

5.5 Nitric acid, 10 percent (V/V). Add, with stirring, 500 mL of concentrated HNO_3 to a flask containing approximately 4000 mL of water. Dilute to 5000 mL with water. Mix well. Reagent shall contain less than 2 µg/L of each target metal.

5.6 Nitric acid, 5 percent (V/V). Add, with stirring, 50 mL of concentrated HNO_3 to 800 mL of water. Dilute to 1000 mL with water. Reagent shall contain less than 2 µg/L of each target metal.

5.7 Nitric acid, 50 percent (V/V). Add, with stirring, 125 mL of concentrated HNO_3 to a flask containing approximately 100 mL of water. Dilute to 250 mL with water. Mix well. Reagent shall contain less than 2 µg/L of each target metal.

5.8 Nitric acid (HNO_3)/hydrogen peroxide (H_2O_2) absorbing solution, 5 percent HNO_3/10 percent H_2O_2. Add carefully, with stirring, 50 mL of concentrated HNO_3 to a 1000-mL volumetric flask containing 500 mL of water. Carefully add 333 mL of 30% H_2O_2 to the flask. Dilute to volume with water. The reagent shall contain less than 2 µg/L of each target metal.

5.9 Hydrochloric acid (8M), HCl - Carefully add with stirring 690 mL of concentrated HCl to a flask containing 250 mL of water. Dilute to 1000 mL with water. Mix well. The reagent shall contain less than 2 µg/L of Hg.

5.10 Hydrogen peroxide, 30 percent (V/V).

5.11 Potassium permanganate, 5 percent (W/V).

5.12 Acidic potassium permanganate ($KMnO_4$) absorbing solution, 4 percent $KMnO_4$ (W/V), 10 percent H_2SO_4 (V/V) - Prepare fresh daily. Carefully mix 100 mL of concentrated H_2SO_4 into 800 mL of water. Add water, with stirring, to make a volume of 1000 mL. This solution is 10% H_2SO_4

(V/V). Dissolve, with stirring, 40 g of $KMnO_4$ into sufficient 10% H_2SO_4 to make a volume of 1 liter. Prepare and store in glass bottles to prevent degradation. The reagent shall contain less than 2 µg/L of Hg.

CAUTION: To prevent autocatalytic decomposition of the permanganate solution, filter the solution through Whatman 541 filter paper. Also, due to reaction of the potassium permanganate with the acid, there may be pressure buildup in the sample storage bottle; these bottles should not be fully filled and should be vented both to relieve excess pressure and prevent explosion due to pressure buildup. Venting is highly recommended, but should not allow contamination of the solution; a No. 70-72 hole drilled in the container cap and Teflon liner is suggested.

5.13 Sulfuric acid, concentrated.

5.14 Silica gel and crushed ice - Same as Method 5.

5.15 Hydrofluoric acid, concentrated.

5.16 Refer to the appropriate preparation and analytical technique for reagent and standard preparation procedures.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Sampling. The complexity of this method is such that, to obtain reliable results, testers should be trained and experienced with the test procedures.

6.1.1 Pretest preparation. Follow the same general procedure given in Method 5, except that, unless particulate emissions are to be determined, the filter need not be desiccated or weighed. All sampling train glassware should first be rinsed with hot tap water and then washed in hot soapy water. Next, glassware should be rinsed three times with tap water, followed by three additional rinses with reagent water. All glassware should then be soaked in a 10% (V/V) nitric acid solution for a minimum of 4 hours, rinsed three times with reagent water, rinsed a final time with acetone, and allowed to air dry. All glassware openings where contamination can occur should be covered until the sampling train is assembled, prior to sampling.

6.1.2 Sampling train calibration. Maintain a laboratory log of all calibrations. Calibrate the sampling train components according to the appropriate sections of Method 5: probe nozzle; pitot tube; metering system; probe heater; temperature gauges; leak-check of the metering system; and barometer.

6.1.3 Preliminary determinations. Same as Method 5.

6.1.4 Preparation of Sampling Train.

6.1.4.1 Follow the same general procedures given in Method 5, except place 100 mL of the nitric acid/hydrogen peroxide solution (Section 5.8) in each of the two HNO_3/H_2O_2 impingers (normally the second and third impingers) as shown in Figure 1. Place 100 mL of the acidic potassium permanganate absorbing solution (Section

5.12) in each of the two permanganate impingers. Transfer approximately 200 to 300 g of preweighed silica gel from its container to the last impinger. Alternatively, the silica gel may be weighed directly in the impinger just prior to train assembly.

6.1.4.2 Several options are available to the tester based on the sampling conditions. The empty first impinger is not needed if the moisture to be collected in the impingers is calculated or determined to be less than 100 mL.

6.1.4.3 Retain for reagent blanks, volumes of the nitric acid/hydrogen peroxide solution and 100 mL of the acidic potassium permanganate solution. These reagent blanks should be labeled and analyzed as described in Section 7. Set up the sampling train as shown in Figure 1. If necessary to ensure leak-free sampling train connections, Teflon tape or other non-contaminating material should be used instead of silicone grease to prevent contamination.

CAUTION: Extreme care should be taken to prevent contamination within the train. Prevent the mercury collection reagent (acidic potassium permanganate) from contacting any glassware of the train which is washed and analyzed for manganese. Prevent hydrogen peroxide from mixing with the acidic potassium permanganate.

6.1.4.4 Alternatively, mercury emissions can be measured in a separate train which measures only mercury emissions by using Method 101A (use only the version of Method 101A which incorporates the changes promulgated on April 25, 1996, in 61 FR 18278 through 18280, or later).

6.1.5 Leak-check procedures. Follow the leak-check procedures given in Method 5: pretest leak-check, leak-checks during the sample run, and post-test leak-checks.

6.1.6 Sampling train operation. Follow the procedures given in Method 5. For each run, record the data required on a data sheet such as the one shown in Figure 5-2 of Method 5. When sampling for Hg, use a procedure analogous to that described in Section 7.1.1 of Method 101A, 40 CFR Part 61, Appendix B, if necessary to maintain the desired color in the last acidified permanganate impinger.

6.1.7 Calculation of percent isokinetic. Same as Method 5.

7.0 PROCEDURE

7.1 Sample recovery. Begin cleanup procedures as soon as the probe is removed from the stack at the end of a sampling period.

7.1.1 The probe should be allowed to cool prior to sample recovery. When it can be safely handled, wipe off all external particulate matter near the tip of the probe nozzle and place a rinsed, non-contaminating cap over the probe nozzle to prevent losing or gaining particulate matter. Do not cap the probe tip tightly while the sampling train is cooling. This normally causes a vacuum to form in the filter holder, thus causing the undesired result of drawing liquid from the impingers into the filter.

7.1.2 Before moving the sampling train to the cleanup site, remove the umbilical cord from the last impinger and cap the impinger. Cap off the filter holder outlet and impinger inlet. Use non-contaminating caps, whether ground-glass stoppers, plastic caps, serum caps, or Teflon tape to close these openings.

7.1.3 Alternatively, the train can be disassembled before the probe and filter holder/oven are completely cooled, if this procedure is followed: Initially disconnect the filter holder outlet/impinger inlet and loosely cap the open ends. Then disconnect the probe from the filter holder or cyclone inlet and loosely cap the open ends. Cap the probe tip and remove the umbilical cord as previously described.

7.1.4 Transfer the probe and filter-impinger assembly to a cleanup area that is clean and protected from the wind and other potential causes of contamination or loss of sample. Inspect the train before and during disassembly and note any abnormal conditions.

7.1.5 The sample is recovered and treated as follows (see schematic in Figure 2). Assure that all items necessary for recovery of the sample do not contaminate it.

7.1.5.1 Container No. 1 (filter). Carefully remove the filter from the filter holder and place it in its identified petri dish container. Acid-washed polypropylene or Teflon coated tweezers or clean disposable surgical gloves rinsed with water should be used to handle the filters. If it is necessary to fold the filter, make certain the particulate cake is inside the fold. Carefully transfer the filter and any particulate matter or filter fibers that adhere to the filter holder gasket to the petri dish by using a dry (acid-cleaned) nylon bristle brush. Do not use any metal-containing materials when recovering this train. Seal the labeled petri dish.

NOTE: Follow the procedure in Section 7.1.5.2 only if determination of particulate emissions are desired in addition to metals emissions. If only metals emissions are to be determined, skip Section 7.1.5.2 and go to Section 7.1.5.3.

7.1.5.2 Container No. 2 (acetone rinse).

7.1.5.2.1 Taking care to see that dust on the outside of the probe or other exterior surfaces does not get into the sample, quantitatively recover particulate matter and any condensate from the probe nozzle, probe fitting (fittings made of plastic such as Teflon, polypropylene, etc. are recommended to prevent contamination by metal fittings, further, if desired a single glass piece may be used, but it is not a requirement of this methodology), probe liner, and front half of the filter holder by washing these components with 100 mL of acetone and placing the wash in a glass container. The use of exactly 100 mL is necessary for the subsequent blank correction procedures. Reagent water may be used instead of acetone when approved by the Administrator and shall be used when specified by the Adminstrator; in these cases, save a water blank and follow the Administrators directions on analysis. In these cases, save a water blank. Perform the acetone rinses as follows: Carefully remove the probe nozzle and clean the inside surface by rinsing with acetone from a wash bottle and brushing with a non-metallic brush. Brush until the acetone rinse shows no visible particles, after which

make a final rinse of the inside surface with acetone. Brush and rinse the sample exposed inside of the Swagelok fitting with acetone in a similar way until no visible particles remain.

7.1.5.2.2 Rinse the probe liner with acetone by tilting and rotating the probe while squirting acetone into its upper end so that all inside surfaces will be wetted with acetone. Allow the acetone to drain from the lower end into the sample container. A funnel may be used to aid in transferring liquid washings to the container. Follow the acetone rinse with a nonmetallic probe brush. Hold the probe in an inclined position, squirt acetone into the upper end as the probe brush is being pushed with a twisting action through the probe; hold a sample container underneath the lower end of the probe, and catch any acetone and particulate matter which is brushed through the probe. Rinse and brush three times or more until no visible particulate matter is carried out with the acetone or until none remains in the probe liner on visual inspection. Rinse the brush with acetone, and quantitatively collect these washings in the sample container. After the brushing, make a final acetone rinse of the probe as described above.

7.1.5.2.3 It is recommended that two people clean the probe to minimize sample losses. Between sampling runs, keep brushes clean and protected from contamination.

7.1.5.2.4 Clean the inside of the front half of the filter holder by rubbing the surfaces with a nylon bristle brush and rinsing with acetone. Rinse each surface three times or more if needed to remove visible particulate. Make a final rinse of the brush and filter holder. Make a final rinse of the brush and filter holder. After all acetone washings and particulate matter have been collected in the sample container, tighten the lid on the sample container so that acetone will not leak out when it is shipped to the laboratory. Mark the height of the fluid level to determine whether or not leakage occurred during transport. Label the container clearly to identify its contents.

7.1.5.3 Container No. 3 (probe rinse). Keep the probe assembly clean and free from contamination as described in Section 7.1.5.2 during the 0.1M nitric acid rinse described below. Rinse the probe liner, probe nozzle, and filter, and front half of the filter holder thoroughly with 100 mL of 0.1 M nitric acid and place the wash into a sample storage container.

NOTE: The use of exactly 100 mL is necessary for the subsequent blank correction procedures. Perform the rinses as applicable and generally as described in Method 12, Section 5.2.2. Record the volume of the combined rinse. Mark the height of the fluid level on the outside of the storage container and use this mark to determine if leakage occurs during transport. Seal the container and clearly label the contents. Finally, rinse the nozzle, probe liner, and front half of the filter holder with water followed by acetone and discard these rinses.

7.1.5.4 Container No. 4 (Impingers 1 through 3, HNO_3/H_2O_2 impingers and moisture knockout impinger, when used, contents and rinses). Due to the potentially large quantity of liquid involved, the tester may place the impinger solutions from Impingers 1, 2, and 3 in more than one container. Measure the liquid in the first three impingers volumetrically to within 0.5 mL using a graduated cylinder or weigh quantitatively to 0.5 g using **calibrated** scales. Record the volume of liquid present. This information is required to calculate the moisture content of the sampled flue gas. Clean each of the first three impingers, the filter support, the back half of the filter housing, and connecting glassware by thoroughly rinsing with 100 mL of 0.1 M nitric acid using the procedure as applicable and generally as described in Method 12, Section 5.2.4.

NOTE: The use of exactly 100 mL of 0.1 M nitric acid rinse is necessary for the subsequent blank correction procedures. Combine the rinses and impinger solutions, measure and record the volume. Mark the height of the fluid level on outside of container to determine if leakage occurs during transport. Seal the container and clearly label the contents.

7.1.5.5 Containers No. 5A (0.1M HNO_3), 5B ($KMnO_4/H_2SO_4$ absorbing solution), and 5C (8M HCl rinse and dilution). If mercury is not being measured in this train, then Impingers 4, 5, and 6, as shown in Figure 1, are not necessary and may be eliminated.

7.1.5.5.1 Pour all the liquid, if any, from the impinger which was empty at the start of the run (normally Impinger 4) and which precedes the two permanganate impingers into a graduated cylinder and measure the volume to within 0.5 mL. This information is required to calculate the moisture content of the sampled flue gas. Place the liquid in Sample Container No. 5A. Rinse the impinger (No. 4) with 100 mL of 0.1M HNO_3 and place this into Container No. 5A. Pour all the liquid from the two permanganate impingers into a graduated cylinder and measure the volume to within 0.5 mL. This information is required to calculate the moisture content of the sampled flue gas. Place this $KMnO_4$ absorbing solution stack sample from the two permanganate impingers into Container No. 5B. Using 100 mL total of the fresh acidified potassium permanganate solution, rinse the permanganate impinger and connecting glass pieces a minimum of three times. Place the rinses into Container No. 5B, carefully assuring transfer of all loose precipitated materials from the two impingers into Container No. 5B. Using 100 mL total of water, rinse the permanganate impingers and connecting glass pieces a minimum of three times, and place the rinses into Container No. 5B, carefully assuring transfer of all loose precipitated material, if any, from the two impingers into Container No. 5B. Mark the height of the fluid level on the outside of the bottle to determine if leakage occurs during transport. See the following note and properly prepare the bottle and clearly label the contents.

NOTE: Due to the potential reaction of the potassium permanganate with the acid, there may be pressure buildup in the sample storage bottle. These bottles shall not be filled full and shall be vented to relieve excess pressure. Venting is required. A No. 70-72 hole drilled in the container cap and Teflon liner is suggested.

7.1.5.5.2 If no visible deposits remain after the above described water rinse, do not rinse with HCl. The previous rinses are designed to remove all of the

permanganate residues, but if any remain, perform the HCl cleanup in a well ventilated area or vent hood as necessary to prevent exposure to any chlorine gases which may be released by the following HCl cleanup procedure. If deposits do remain on the glassware after this water rinse, wash the impinger surfaces with 25 mL of 8M HCl, and place the wash in a separate sample container labeled Container No. 5C that contains 200 mL of water. Wash the impinger walls and stem with the HCl by turning the impinger on its side and rotating it so that the HCl contacts all inside surfaces. Use a total of only 25 mL of 8M HCl for rinsing both permanganate impingers combined. Rinse the first impinger, then pour the actual rinse used for the first impinger into the second impinger for its rinse. Finally, pour the 25 mL of 8M HCl rinse carefully with stirring into Container No. 5C. Mark the height of the fluid level on the outside of the bottle to determine if leakage occurs during transport.

7.1.5.6 Container No. 6 (silica gel). Note the color of the indicating silica gel to determine whether it has been completely spent and make a notation of its condition. Transfer the silica gel from its impinger to its original container and seal. The tester may use a funnel to pour the silica gel and a rubber policeman to remove the silica gel from the impinger. The small amount of particles that may adhere to the impinger wall need not be removed. Do not use water or other liquids to transfer the silica gel since weight gained in the silica gel impinger is used for moisture calculations. Alternatively, if a balance is available in the field, record the weight of the spent silica gel (or silica gel plus impinger) to the nearest 0.5g.

7.1.5.7 Container No. 7 (acetone blank). If particulate emissions are to be determined, at least once during each field test, place 100-mL portion of the acetone used in the sample recovery process into a labeled container for use in the front-half field reagent blank. Seal the container.

7.1.5.8 Container No. 8A (0.1 M nitric acid blank). At least once during each field test, place 300 mL of the 0.1 M nitric acid solution used in the sample recovery process into a labeled container for use in the sample recovery process into a labeled container for use in the front-half and back-half field reagent blanks. Seal the container.

7.1.5.9 Container No. 8B (water blank). At least once during each field test, place 100 mL of the water used in the sample recovery process into a labeled Container No. 8B. Seal the container.

7.1.5.10 Container No. 9 (5 percent nitric acid/10 percent hydrogen peroxide blank). At least once during each field test, place 200 mL of the 5% nitric acid/10% hydrogen peroxide solution used as the nitric acid impinger reagent into a labeled container for use in the back-half field reagent blank. Seal the container.

7.1.5.11 Container No. 10 (acidified potassium permanganate blank). At least once during each field test, place 100 mL of the acidified potassium permanganate solution used as the impinger solution and in the sample recovery process into a labeled container for use in the back-half field reagent blank for mercury analysis. Prepare the container as described in Section 7.2.5.5.1 note.

7.1.5.12 Container No. 11 (8M HCl blank). At least once during each field test, place 200 mL of water into a sample container. Then pour 25 mL of 8M HCl carefully with stirring into the 200 mL of water in the container. Mix well and seal the container.

7.1.5.13 Container No. 12 (filter blank). Once during each field test, place an unused filter from the same lot as the sampling filters in a labeled petri dish. Seal the petri dish. This will be used in the front-half field reagent blank.

7.2 Sample preparation. Note the level of the liquid in each of the containers and confirm on the analysis sheet whether or not leakage occurred during transport. If a noticeable amount of leakage has occurred either void the sample or use approved methods to correct the final results. A diagram illustrating sample preparation and analysis procedures for each of the sample train components is shown in Figure 3. If the sampling train uses an optional cyclone, the cyclone catch should be prepared and digested using the same procedures described for the filters and combined with the digested filter samples. Acid digestion is performed by using either prescribed digestion techniques of this manual, or the Method 29 procedures.

7.2.1 Container No. 1 (filter). If particulate emissions are being determined, then desiccate the filter and filter catch without added heat and weigh to a constant weight as described in Section 4.3 of Method 5. For analysis of metals, divide the filter with its filter catch into portions containing approximately 0.5 g each and place into the analyst's choice of either individual fluorocarbon based microwave pressure relief vessels or Parr® Bombs. Add 6 mL of concentrated nitric acid and 4 mL of concentrated hydrofluoric acid to each vessel. For microwave heating, microwave the sample according to Method 3051. For conventional heating, heat the Parr® Bombs in an oven at 140°C (285°F) for 6 hours following the manufacturer's recommendations for Bomb loading, assembly and disassembly, cleaning, and handling. Cool the samples to room temperature and combine with the acid digested probe rinse as required in Section 7.2.3.

NOTE: Hydrofluoric acid (HF) has been identified as an exceptional health and contact hazard. Burns and other symptoms can be severe and may not appear immediately. The analyst should perform all operations with HF under appropriate laboratory conditions (i.e., in a fume hood suitable for HF work), should be fully informed regarding the appropriate safety data (e.g., all hazard warnings, storage and handling requirements, spill cleanup procedures, and emergency treatments for exposure), and should wear the appropriate laboratory protective equipment (e.g., goggles, face shield, lab coat, rubber apron, long rubber gloves) when preparing and handling digestates and other solutions containing HF.

7.2.2 Container No. 2 (acetone rinse). Measure the liquid in this container either volumetrically to ±1 mL or gravimetrically to ±0.5 g. Transfer the contents to an acid-cleaned tared 250-mL beaker and evaporate to dryness at ambient temperature and pressure. If particulate emissions are being determined, desiccate for 24 hours without added heat, weigh to a constant weight according to the procedures described in Section 4.3 of Method 5, and report the results to the nearest 0.1 mg. Redissolve the residue with 10 mL concentrated nitric acid and carefully, with stirring, combine the resultant sample including all liquid and any particulate matter with Container No. 3 prior to beginning the Section 7.2.3.

7.2.3 Container No. 3 (probe rinse). The pH of this sample shall be 2 or lower. If the pH is higher, the sample should be acidified by careful addition, with stirring, with concentrated nitric acid to pH 2. The sample should be rinsed into a beaker with water and

the beaker should be covered with a ribbed watchglass. The sample volume should be reduced to approximately 20 mL by heating on a hot plate at a temperature just below boiling. Then follow one of the digestion procedures listed below.

7.2.3.1 Digest the sample using the appropriate method (Method 3010, 3015, or Parr Bomb), using the HF modification and then continuing to follow the procedures described in Section 7.2.1.

7.2.3.2 Combine with the digestate prepared in Section 7.2.1. The resultant combined sample is a Fraction 1 precursor. Filter the combined solution of the acid digested filter and probe rinse samples using Whatman 541 filter paper. Dilute to 300 mL (or the appropriate volume for the expected metals concentration) with water. This dilution is Fraction 1. Measure and record the volume of the Fraction 1 solution to within 0.1 mL. Quantitatively remove a 50-mL aliquot and label as Fraction 1B. Label the remaining 250 mL portion as Fraction 1A. Fraction 1A is used for ICP-AES, ICP-MS, or AA analysis for all metals except mercury. Fraction 1B is used for the determination of front-half mercury.

7.2.4 Container No. 4 (Impingers 1-3). Measure and record the total volume of this sample (Fraction 2) to within 0.5 mL. Remove a 75-to 100-mL aliquot for mercury analysis and label as Fraction 2B. Label the remaining portion of Container No. 4 as aliquot Fraction 2A. Aliquot Fraction 2A defines the volume of 2A prior to digestion. All of aliquot Fraction 2A is digested to produce concentrated Fraction 2A. Concentrated Fraction 2A defines the volume of 2A after digestion which is normally 150 mL. Concentrated Fraction 2A is analyzed for all the metals except mercury. The Fraction 2B aliquot should be prepared and analyzed for mercury as described in Section 7.4.7. Fraction 2A shall be pH 2 or lower. If necessary, use concentrated nitric acid to lower Fraction 2A to pH 2. The sample should be rinsed into a beaker with water and the beaker should be covered with a ribbed watchglass. The sample volume should be reduced to approximately 20 mL by heating on a hot plate at a temperature just below boiling. Acid digestion is performed by using either prescribed digestion techniques of this manual, or the Method 29 procedures.

7.2.5 Container Nos. 5A, 5B, and 5C (Impingers 4, 5, and 6). Keep these samples separate from each other.

7.2.5.1 Measure and record the volumes of 5A and 5B each to within 0.5 mL. Dilute Sample 5C to 500 mL with water. The Samples 5A, 5B, and 5C are referred to respectively as Fractions 3A, 3B, and 3C. Follow the analysis procedures described in Section 7.4.

7.2.5.2 Because the permanganate rinse and water rinse have the capability to recover a high percentage of the mercury from the permanganate impingers, the amount of mercury in the HCl rinse (Fraction 3C) may be very small, possibly even insignificantly small. However, as instructed in this method, add the total of any mercury measured in and calculated for the HCl rinse (Fraction 3C) to that for Fractions 1B, 2B, 3A, and 3B for calculation of the total sample mercury concentration.

7.2.6 Container No. 6 (silica gel). Weigh the spent silica gel (or silica gel plus impinger) to the nearest 0.5 g using a balance. (This step may be conducted in the field).

7.3 Calibration

Refer to the appropriate analytical methods for the proper calibration procedures.

7.4 Sample analysis.

7.4.1 For each sampling train, seven individual samples are generated for analysis. A schematic identifying each sample and the prescribed sample preparation and analysis scheme is shown in Figure 3. The first two samples, labeled Fractions 1A and 1B, consist of the digested samples from the front half of the train. Fraction 1A is for ICP-AES and AA analysis as described in Section 7.4.5. Fraction 1B is for determination of front-half mercury as described in Section 7.4.7.

7.4.2 The back half of the train was used to prepare the third through seventh samples. The third and fourth samples, labeled Fractions 2A and 2B, contain the digested samples from the moisture knockout, if used, and HNO_3/H_2O_2 Impingers 1 through 3. Fraction 2A is for ICP-AES or AA analysis. Fraction 2B will be analyzed for mercury.

7.4.3 Samples 5A, 5B, and 5C are labeled Fractions 3A, 3B, and 3C, respectively. They consist of the impinger contents and rinses from the empty Impinger 4 and the permanganate Impingers 5 and 6. These samples are analyzed for mercury as described in Section 7.4.7. The total back-half mercury catch is determined from the sum of Fraction 2B and Fraction 3A, 3B, and 3C.

7.4.4 Initially, analyze all samples for iron, aluminum, and all the target metals except mercury . If iron and aluminum are present in the sample, the sample may have to be diluted so that each of these elements is at a concentration of less than 50 ppm to reduce their spectral interferences on arsenic, cadmium, chromium, and lead.

> NOTE: When analyzing samples in a hydrofluoric acid matrix, an alumina torch should be used. Since all front-half samples will contain hydrofluoric acid, use an alumina torch.

7.4.5 ICP-AES analysis. Fraction 1A and Fraction 2A are analyzed by ICP-AES using Method 6010. Refer to Method 6010 for the proper analytical procedures.

7.4.6 AA by direct aspiration and/or graphite furnace. If analysis of metals in Fraction 1A and Fraction 2A using graphite furnace or direct aspiration AA is desired, Table A-2 should also be consulted to determine possible interferences and techniques to use for their minimization. Refer to Vol. 1A of this manual to determine the appropriate analytical protocol.

7.4.7 Cold vapor AA mercury analysis. Fraction 1B, Fraction 2B, and Fraction 3A, 3B, and 3C should be analyzed separately for mercury using cold vapor atomic absorption spectrometry following the method outlined in Method 7470. Refer to Method 7470 for the proper analytical protocol. If no prior knowledge exists of the expected amount of mercury

in the sample, dilute a 1-mL to 10-mL aliquot of each original sample to 100 mL. Record the amount of the aliquot used for dilution to 100 mL. Digest the sample according to Method 7470. To determine the stack emission value for mercury, the amount of the aliquot of the sample used for dilution and analysis is dependent on the amount of mercury in the aliquot: the total amount of mercury in the aliquot used for analysis must be less than 1 ug, and within the range (zero to 1000 ng) of the calibration curve.

7.4.8 Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) may be used for analysis of Sb, As, Ba, Be, Cd, Cr, Co, Cu, Pb, Mn, Ni, As, Tl and Zn. Refer to Method 6020 for the proper analytical procedure.

7.5 Calculations

7.5.1 Dry gas volume. Using the data from this test, calculate $V_{m(std)}$, the dry gas sample volume at standard conditions as outlined in Section 6.3 of Method 5.

7.5.2 Volume of water vapor and moisture content. Using the data obtained from this test, calculate the volume of water vapor $V_{w(std)}$ and the moisture content B_{ws} of the stack gas. Use Equations 5-2 and 5-3 of Method 5.

7.5.3 Stack gas velocity. Using the data from this test and Equation 2-9 of Method 2, calculate the average stack gas velocity.

7.5.4 Metals (except mercury) in source sample.

7.5.4.1 Fraction 1A, front half, metals (except Hg). Calculate the amount of each metal collected in Fraction 1 of the sampling train using the following equation:

$$M_{fh} = C_{a1} F_d V_{soln,1} \qquad \text{Eq. } 1^1$$

where:

M_{fh} = total mass of each metal (except Hg) collected in the front half of the sampling train (Fraction 1), µg.

C_{a1} = concentration of metal in sample Fraction 1A as read from the standard curve (µg/mL).

F_d = dilution factor (F_d = the inverse of the fractional portion of the concentrated sample in the solution actually used in the instrument to produce the reading C_{a1}. For example, when a 2 mL volume of Fraction 1A is diluted to 10 mL, F_d = 5).

$V_{soln,1}$ = total volume of digested sample solution (Fraction 1), mL.

7.5.4.2 Fraction 2A, back half, metals (except Hg). Calculate the amount of each metal collected in Fraction 2 of the sampling train using the following equation.

$$M_{bh} = C_{a2} F_a V_a \qquad \text{Eq. } 2^1$$

[1]If Fractions 1A and 2A are combined, proportional aliquots must be used. Appropriate changes must be made in Equations 1-3 to reflect this approach.

where:

M_{bh} = total mass of each metal (except Hg) collected in the back half of the sampling train (Fraction 2), µg.

C_{a2} = concentration of metal in sample concentrated Fraction 2A, as read from the standard curve (µg/mL).

F_a = aliquot factor, volume of Fraction 2 divided by volume of aliquot Fraction 2A. See Section 7.2.4.

V_a = total volume of digested sample solution (concentrated Fraction 2A), mL. See Section 7.2.4.

7.5.4.3 Total train, metals (except Hg). Calculate the total amount of each of the quantified metals collected in the sampling train as follows:

$$M_t = (M_{fh} - M_{fhb}) + (M_{bh} - M_{bhb}) \quad \text{Eq. } 3^1$$

where:

M_t = total mass of each metal (separately stated for each metal) collected in the sampling train, µg.

M_{fhb} = bank correction value for mass of metal detected in front-half field reagent blank, µg.

M_{bhb} = blank correction value for mass of metal detected in back-half field reagent blank, µg.

NOTE: If the measured blank value for the front half (M_{fhb}) is in the range 0.0 to "A" µg [where "A" µg equals the value determined by multiplying 1.4 µg/in.^{2} times the actual area in square inches of the filter used in the emission sample], M_{fhb} may be used to correct the emission sample value (M_{fh}); if M_{fhb} exceeds "A" µg, the greater of the two following values may be used: "A" µg, or the lesser value of M_{fhb} or 5 percent of M_{fh}.

If the measured blank value for the back half (M_{bhb}) is in the range 0.0 to 1 µg, M_{bhb} may be used to correct the emission sample value (M_{bh}); if M_{bhb} exceeds 1 µg, the greater of the two following values may be used: 1 µg or the lesser value of M_{bhb}or 5 percent of M_{bh}.

7.5.5 Mercury in source sample.

7.5.5.1 Fraction 1B, front half, Hg. Calculate the amount of mercury collected in the front half, Fraction 1, of the sampling train using the following equation:

$$Hg_{fh} = \left(\frac{Q_{fh}}{V_{f1B}}\right) \times V_{soln,1} \quad \text{Eq. 4}$$

[1]If Fractions 1A and 2A are combined, proportional aliquots must be used. Appropriate changes must be made in Equations 1-3 to reflect this approach.

where:

Hg_{fh} = total mass of mercury collected in the front half of the sampling train (Fraction 1), µg.
Q_{fh} = quantity of mercury in analyzed sample, µg.
$V_{soln,1}$ = total volume of digested sample solution (Fraction 1), mL.
V_{f1B} = volume of Fraction 1B analyzed, mL. See the following Note.

NOTE: V_{f1B} is the actual amount of Fraction 1B analyzed. For example, if 1 mL of Fraction 1B were diluted to 100 mL to bring it into the proper analytical range, and 1 mL of the 100 mL dilution was analyzed, V_{f1B} would be 0.01.

7.5.5.2 Fraction 2B and Fractions 3A, 3B, and 3C, back half, Hg. Calculate the amount of mercury collected in Fraction 2 using Equation 5 and Fractions 3A, 3B, and 3C using Equation 6. Calculate the total amount of mercury collected in the back half of the sampling train using Equation 7.

$$Hg_{bh2} = \frac{Q_{bh2}}{V_{f2B}} \times V_{soln,2} \qquad \text{Eq. 5}$$

where:

Hg_{bh2} = total mass of mercury collected in Fraction 2, µg.
Q_{bh2} = quantity of mercury in analyzed sample, µg.
$V_{soln,2}$ = total volume of Fraction 2, mL.
V_{f2B} = volume of Fraction 2B analyzed, mL (see the following note).

NOTE: V_{f2b} is the actual amount of Fraction 2B analyzed. For example, if 1 mL of Fraction 2B were diluted to 10 mL to bring it into the proper analytical range, and 5 mL of the 10-mL dilution was analyzed, V_{f2b} would be 0.5 mL. Use Equation 6 to calculate separately the back-half mercury for Fractions 3A, 3B, and 3C.

$$Hg_{bh3(A,B,C)} = \frac{Q_{bh3(A,B,C)}}{V_{f3(A,B,C)}} \times V_{soln,3(A,B,C)} \qquad \text{Eq. 6}$$

where:

$Hg_{bh3(A,B,C)}$ = total mass of mercury collected separately in Fractions A, 3B, or 3C, µg.
$Q_{bh3(A,B,C)}$ = quanty of mercury in separately analyzed samples, µg.
$V_{f3(A,B,C)}$ = volume Fraction 3A, 3B, or 3C analyzed, mL (see above and calculate similarly).
$V_{soln,3(A,B,C)}$ = total volume of Fraction 3A, 3B, or 3C, mL.

$$Hg_{bh} = Hg_{bh2} + Hg_{bh3A} + Hg_{bh3B} + Hg_{bh3C} \qquad \text{Eq. 7}$$

where:

Hg_{bh} = total mass of mercury collected in the back half of the sampling train, ug.

7.5.5.3 Total train mercury catch. Calculate the total amount of mercury collected in the sampling train using Equation 8.

$$Hg_t = (Hg_{fh} - Hg_{fhb}) + (Hg_{bh} - Hg_{bhb}) \quad \text{Eq. 8}$$

where:

Hg_t = total mass of mercury collected in the sampling train, µg.
Hg_{fhb} = blank correction value for mass of mercury detected in front-half field reagent blank, µg.
Hg_{bhb} = blank correction value for mass of mercury detected in back-half field reagent blank, µg.

NOTE: If the total of the measured blank values ($Hg_{fhb} + Hg_{bhb}$) is in the range of 0 to 6 ug, then the total may be used to correct the emission sample value ($Hg_{fh} + Hg_{bh}$); if it exceeds 6 µg, the greater of the following two values may be used: 6 µg or 5 percent of the emission sample value ($Hg_{fh} + Hg_{bh}$).

7.5.6 Metal concentration of stack gas. Calculate each metal separately for the cadmium, total chromium, arsenic, nickel, manganese, beryllium, cobalt, copper, lead, phosphorus, thallium, silver, barium, zinc, selenium, antimony, and mercury concentrations in the stack gas (dry basis, adjusted to standard conditions) as follows:

$$C_s = K_4 (M_t/V_{m(std)}) \quad \text{Eq. 9}$$

where:

C_s = concentration of each metal in the stack gas, mg/dscm.
K_4 = 10^{-3} mg/µg.
M_t = total mass of each metal collected in the sampling train, µg; (substitute Hg_t for M_t for the mercury calculation).
$V_{m(std)}$ = volume of gas sample as measured by the dry gas meter, corrected to dry standard conditions, dscm.

7.5.7 Isokinetic variation and acceptable results. Same as Method 5, Sections 6.11 and 6.12, respectively.

8.0 QUALITY CONTROL

8.1 Sampling Blanks.

Field Reagent Blanks (FRBs). When analyzed, the blank samples in Container Nos. 7 through 12 shall be processed, digested, and analyzed as follows. Digest and process one of the filters from Container No. 12 contents per Section 7.2.1, 100 mL from Container No. 7 per Section 7.2.2, and 100 mL from Container No. 8 per Section 7.2.3. This produces Fraction Blank 1A and Fraction Blank 1B from Fraction Blank 1. (If desired, the other two filters may be digested separately according to Section 7.2.1, diluted separately to 300 mL each, and analyzed separately to produce a blank value for each of the two additional filters. If these analyses are performed, they will produce two additional values for each of Fraction Blank 1A and Fraction Blank 1B. The three Fraction Blank 1A values will be calculated as three values of M_{fhb} in Equation 3 of Section 7.5.4.3, then the three values shall be totalled and divided by three to become the value M_{fhb} to be used in the computation of M_t by Equation 3. Similarly, the three Fraction Blank 1B values will be calculated separately as three values, totalled, averaged, and used as the value for Hg_{fhb} in Equation 8 of Section 7.5.5.3. The analyses of the two extra filters are optional and are not a requirement of this method, but if the analyses are performed, the results must be considered as described above.) Combine 100 mL of Container No. 8A with 200 mL of the contents of Container No. 9 and digest and process the resultant volume per Section 7.2.4. This produces concentrated Fraction Blank 2A and Fraction Blank 2B from Fraction Blank 2. A 100-mL portion of Container No. 8A is Fraction Blank 3A. Combine 100 mL of the contents of Container No. 10 with 33 mL of the contents of Container No. 8B. This produces Fraction Blank 3B. (Use 400 mL as the volume of Fraction Blank 3B when calculating the blank value. Use the actual volumes when calculating all the other blank values). Dilute 225 mL of the contents of Container No. 11 to 500 mL with water. This produces Fraction Blank 3C. Analyze Fraction Blank 1A and Fraction Blank 2A per Section 7.4.5 and/or Section 7.4.6 Analyze Fraction Blank 1B, Fraction Blank 2B, and Fraction Blank 3A, 3B, and 3C per Section 7.4.7. The analysis of Fraction Blank 1A produces the front-half reagent blank correction values for the metals except mercury; the analysis of Fraction Blank 1B produces the front-half reagent blank correction value for mercury. The analysis of Fraction Blank 2A produces the back-half reagent blank correction values for the metals except mercury, while separate analysis of Fraction Blanks 2B and 3 produce the back-half reagent blank correction value for mercury.

8.2 Quality Control Samples. The following quality control samples should be analyzed. All appropriate Chapter One quality control procedures should be followed.

8.2.1 ICP-AES or ICP-MS analysis. Follow the quality control shown in Chapter One and Section 8 of Method 6010 or 6020 as appropriate.

8.2.2 Direct aspiration and/or graphite furnace AA analysis for antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, nickel, manganese, mercury, phosphorus, selenium, silver, thallium, and zinc. All samples should be analyzed in duplicate. Perform a post-digestion spike on at least one front-half sample and one back-half sample or one combined sample. If recoveries of less than 75 percent or greater than 125 percent are obtained for the post-digestion spike, analyze each sample by the method of standard additions.

8.2.3 Cold vapor AA analysis for mercury. All samples should be analyzed in duplicate. Perform a post-digestion or matrix spike on one sample from the nitric acid impinger portion (must be within 25% or samples must be analyzed by the method of standard additions).

9.0 METHOD PERFORMANCE

9.1 To ensure optimum sensitivity in obtaining the measurements, the concentrations of target metals in the solutions are suggested to be at least ten times the analytical detection limits. Under certain conditions, and with greater care in the analytical procedure, this concentration can be as low as approximately three times the analytical detection limit. In all cases, on at least one sample (run) in the source test and for each metal analyzed, repetitive analyses, method of standard additions (MSA), serial dilution, or matrix spike addition, etc., shall be used to establish the quality of the data.

9.2 Actual in-stack method detection limits will be determined based on actual source sampling parameters and analytical results as described above. If required, the method in-stack detection limits can be made more sensitive than those shown in Table 2 for a specific test by using one or more of the following options:

- A 1-hour sampling run collects a stack gas sampling volume of about 1.25 m^3. If the sampling time is increased and 5 m^3 are collected, the in-stack method detection limits would be one fourth of the values shown in Table A-1 (i.e., the method is four times more sensitive than an hour run).

- The in-stack detection limits assume that all of the sample is digested (with exception of the aliquot for mercury) and the final liquid volumes for analysis are 300 mL for the front half (Fraction 1) and 150 mL for the back half (Fraction 2A). If the volume of the front half is concentrated from 300 mL to 30 mL, the front half in-stack detection limits would be one tenth of the values shown above (ten times more sensitive). If the back-half volume is concentrated from 150 mL to 25 mL, the in-stack detection limits would be one sixth of the above values. Matrix effects checks are necessary on analyses of samples and typically are of greater significance for samples that have been concentrated to less than the normal sample volume. Reduction to a volume of less than 25 mL may not allow redissolving of the residue and may increase interference by other compounds.

- When both of the above two improvements are used on one sample at the same time, the resultant improvements are multiplicative. For example, where stack gas volume is increased by a factor of five and the total liquid sample digested volume of both the front and back halves is reduced by factor of six, the in-stack method detection limit is reduced by a factor of thirty (the method is thirty times more sensitive).

- Conversely, reducing stack gas sample volume and increasing sample liquid volume will increase detection limits (i.e., the method would be less sensitive). The front-half and back-half samples (Fractions 1A plus 2A) can be combined proportionally prior to analysis. The resultant liquid volume (excluding the mercury fractions, which must be analyzed separately) is recorded. Combining the sample as described does not

allow determination (whether front or back half) of where in the train the sample was captured. The in-stack method detection limit then becomes a single value for all metals except mercury, for which the contribution of the mercury fraction must be considered.

- The above discussion assumes no blank correction.

9.3 Using (1) the procedures described in this method, (2) the analytical detection limits listed in Section 1, (3) a volume of 300 mL for the front half and 150 mL for the back-half samples, and (4) a stack gas sample volume of 1.25 m^3, the corresponding in-stack method detection limits are presented in Table A-2 and calculated as shown:

$$\frac{A \times B}{C} = D$$

where:

A = analytical detection limit, µg/mL.
B = volume of sample prior to aliquot for analysis, mL.
C = stack sample volume, dscm (dsm^3).
D = in-stack detection limit, $\mu g/m^3$.

Values in Table A-2 are calculated for the front and back half and/or the total train.

TABLE 2. IN-STACK METHOD DETECTION LIMITS (µg/m^3)
FOR TRAIN FRACTIONS USING ICP-AES AND AA

Metal	Front Half Fraction 1 Probe and Filter	Back Half Fraction 2 Impingers 1-3	Back Half Fraction 3 Impingers 4-5	Total Train
Antimony	7.7 (0.7)*	3.8 (0.4)*		11.5 (1.1)*
Arsenic	12.7 (0.3)*	6.4 (0.1)*		19.1 (0.4)*
Barium	0.5	0.3		0.8
Beryllium	0.07 (0.05)*	0.04 (0.03)*		0.11 (0.08)*
Cadmium	1.0 (0.02)*	0.5 (0.01)*		1.5 (0.03)*
Chromium	1.7 (0.2)*	0.8 (0.1)*		2.5 (0.3)*
Cobalt	1.7 (0.2)*	0.8 (0.1)*		2.5 (0.3)*
Copper	1.4	0.7		2.1
Lead	10.1 (0.2)*	5.0 (0.1)*		15.1 (0.3)*
Manganese	0.5 (0.2)*	0.2 (0.1)*		0.7 (0.3)*
Mercury	0.6**	3.0**	2.0**	5.6**
Nickel	3.6	1.8		5.4
Phosphorus	18.0	9.0		27.0
Selenium	18.0 (0.5)*	9.0 (0.3)*		27.0 (0.8)*
Silver	1.7	0.9		2.6
Thallium	9.6 (0.2)*	4.8 (0.1)*		14.4 (0.3)*
Zinc	0.5	0.3		0.8

( )* Detection limit when analyzed by GFAA.
** Detection limit when analyzed by CVAA, estimated for back-half and total train.

NOTE: Actual method in-stack detection limits will be determined based on actual source sampling parameters and analytical results as described earlier in this section.

TABLE 3. APPLICABLE TECHNIQUES, METHODS, AND MINIMIZATION OF INTERFERENCE FOR AA ANALYSIS

Metal	Technique	Method No.	Wavelength (nm)	Interference	
				Cause	Minimization
Sb	Aspiration	7040	217.6	1000 mg/mL Pb Ni, Cu, or acid	Use secondary wavelength of 231.1 nm. Match sample & standards acid concentration or use nitrous oxide/acetylene flame
Sb	Furnace	7041	217.6	High Pb	Secondary wavelength or Zeeman correction
As	Furnace	7060	193.7	Arsenic vola-tilization Aluminum	Spiked samples & add nickel nitrate solution to digestates prior to analyses Use Zeeman background correction
Ba	Aspiration	7080	553.6	Calcium Barium ionization	High hollow cathode current & narrow band set 2 mL of KCl per 100 mL of sample
Be	Aspiration	7090	234.9	500 ppm Al High Mg & Si	Add 0.1% fluoride Use method of standard additions
Be	Furnace	7091	234.9	Be in optical path	Optimize parameters to minimize effects
Cd	Aspiration	7130	228.8	Absorption & light scattering	Background correction is required
Cd	Furnace	7131	228.8	As above Excess chloride Pipet tips	As above Ammonium phosphate used as a matrix modifier Use cadmium-free tips

(continued)

TABLE 3 (CONTINUED)

Metal	Technique	Method No.	Wavelength (nm)	Interference	
				Cause	Minimization
Cr	Aspiration	7190	357.9	Alkali metal Absorption & scattering	KCl ionization suppressant in sample & standard Consult manufacturer's literature
Cr	Furnace	7191	357.9	200 mg/L calcium & phosphate	All calcium nitrate for a known constant effect and to eliminate effect of phosphate
Cu	Aspiration	7210	324.7	Absorpt & scatter	Consult manufacturer's manual
Fe	Aspiration	7380	283.3	Contamination	Great care taken to avoid contamination
Pb	Aspiration	7420	283.3	217.0 nm alternative	Background correction required
Pb	Furnace	7421	283.3	Poor recoveries	Matrix modifier, add 10 uL of phosphorus acid to 1-mL of prepared sample in sampler cup
Mn	Aspiration	7460	279.5	403.1 nm alternative	Background correction required
Ni	Aspiration	7520	232.0	352.4 nm alternative Fe, Co, & Cr Nonlinear response	Background correction required Matrix matching or a nitrous-oxide/acetyl flame Sample dilution or use 352.4 nm line

(continued)

TABLE 3 (CONTINUED)

Metal	Technique	Method No.	Wavelength (nm)	Interference	
				Cause	Minimization
Se	Furnace	7740	196.0	Volatility	Spike samples & reference materials & add nickel nitrate to minimize volatilization
				Adsorpt & scatter	Background correction is required & Zeeman background correction can be useful
Ag	Aspiration	7760	328.1	Absorpt & scatter	Background correction is required
				AgCl insoluble	Avoid hydrochloric acid unless silver is in solution as a chloride complex
				Viscosity	Sample & standards monitored for aspiration rate
Tl	Aspiration	7840	276.8		Background correction is required Hydrochloric acid should not be used
Tl	Furnace	7841	276.8		Background correction is required
				Hydrochloric acid or chloride	Verify that losses are not occurring for volatization by spiked samples or standard additions Palladium is a suitable matrix modifier
Zn	Aspiration	7950	213.9	High Si, Cu & P	Strontium removes Cu and phosphate
				Contamination	Care should be taken to avoid contamination

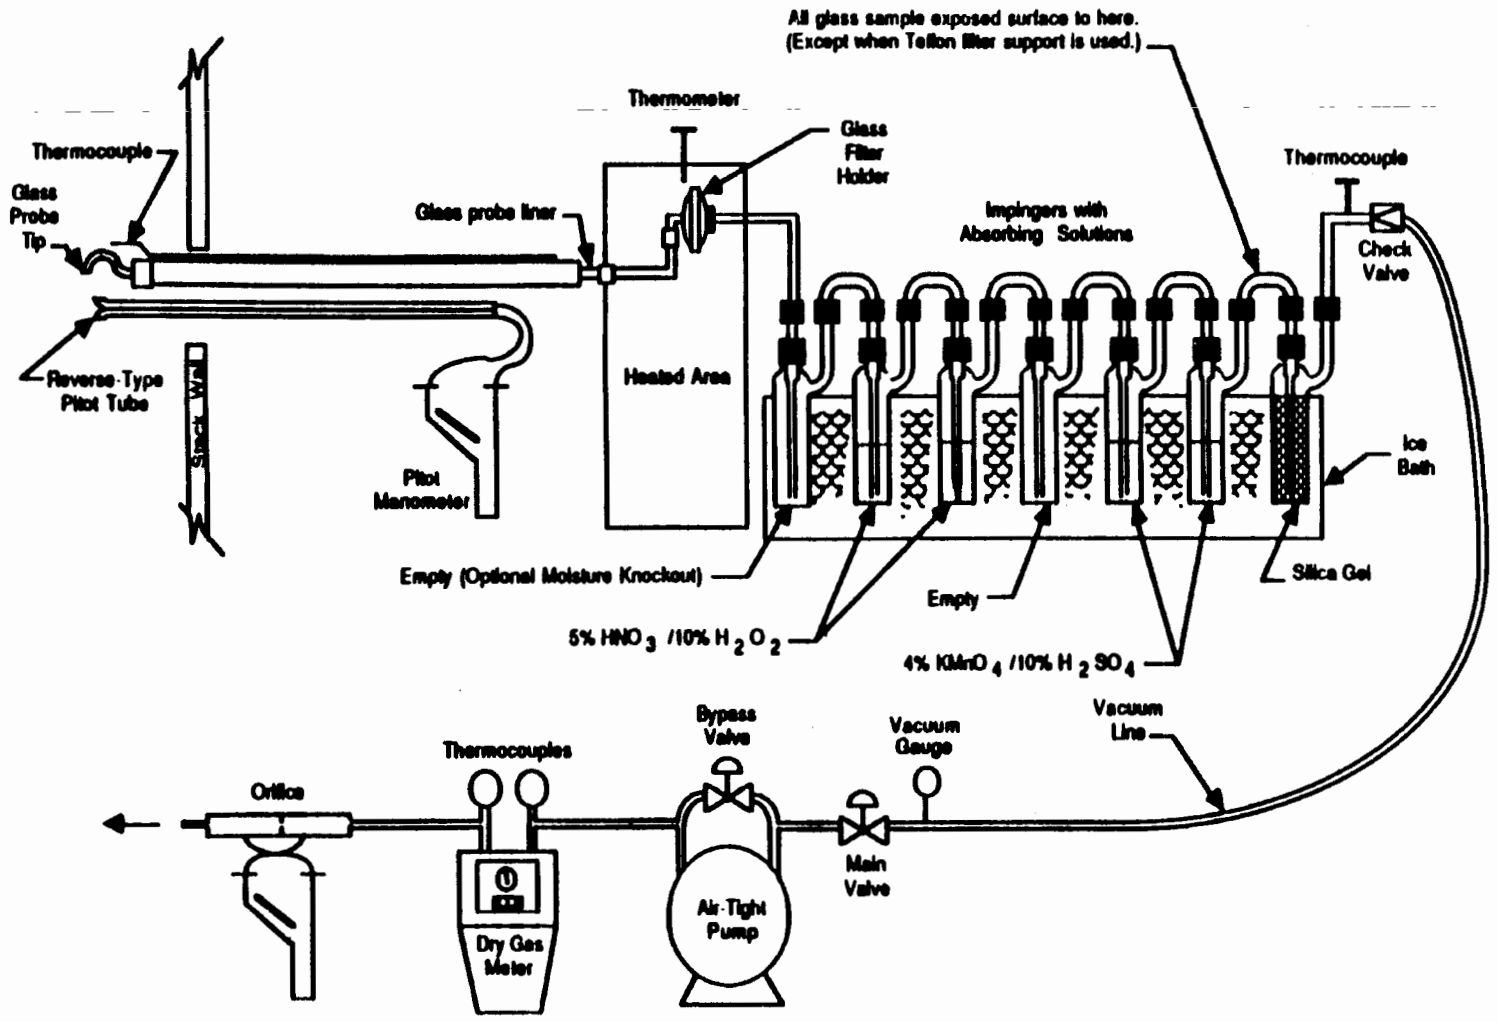

FIGURE 1. SCHEMATIC OF MULTIPLE METALS SAMPLING TRAIN CONFIGURATION

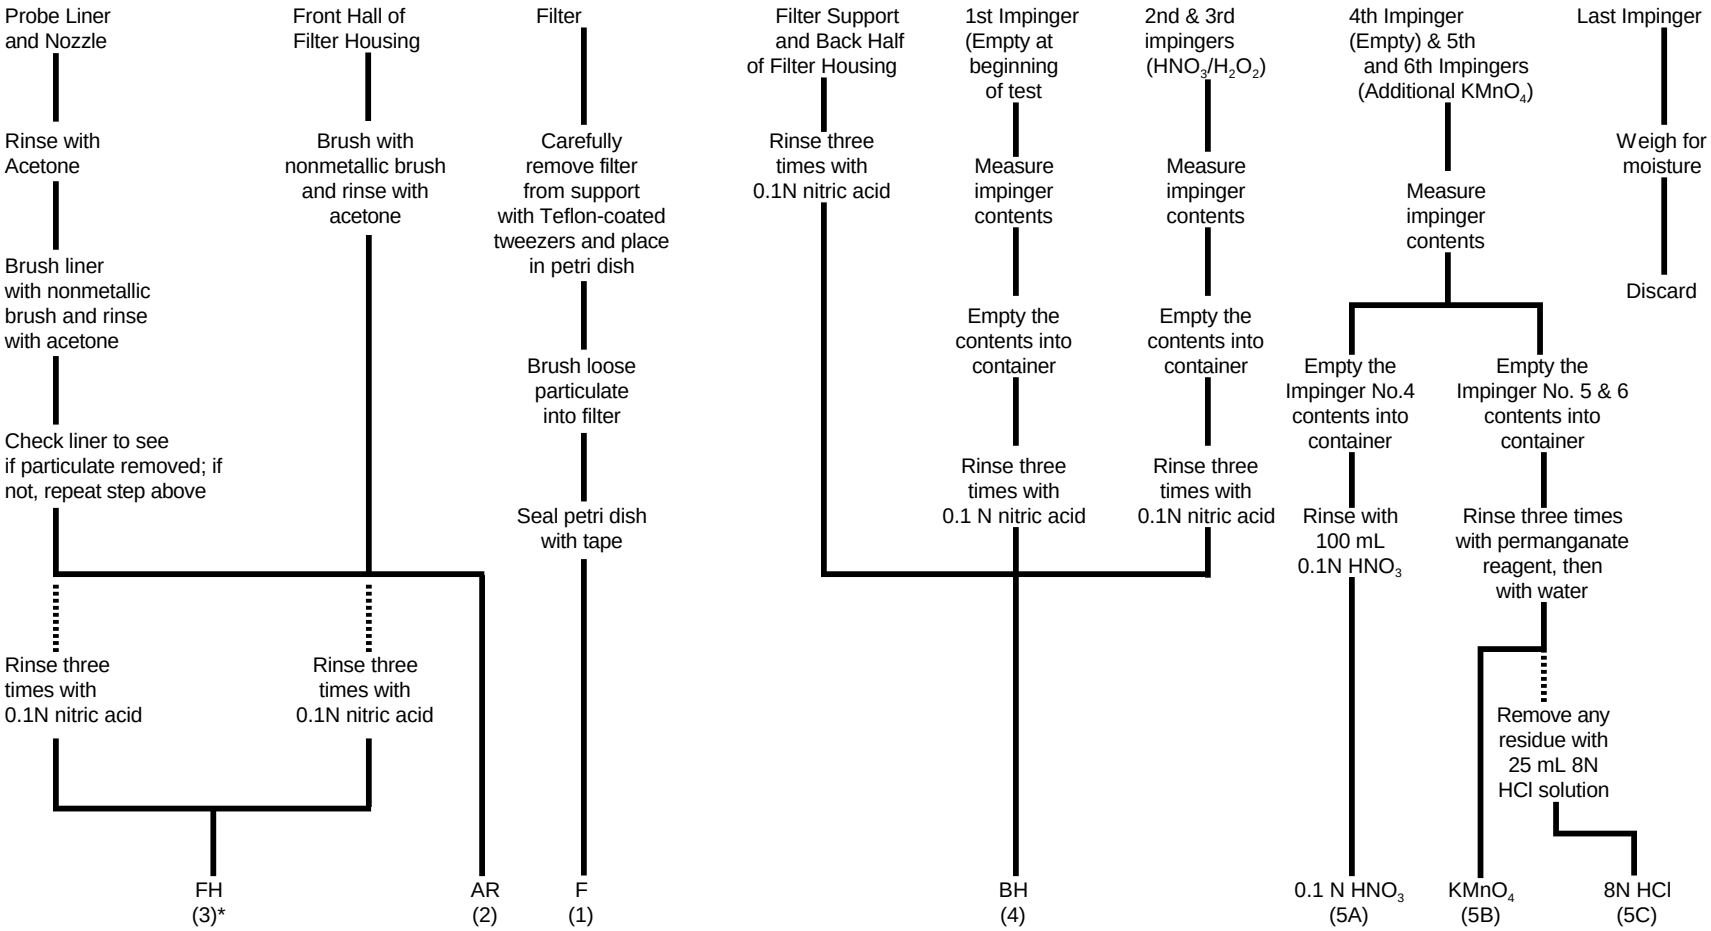

* Number in parentheses indicates container number

FIGURE 2. SAMPLE RECOVERY SCHEME

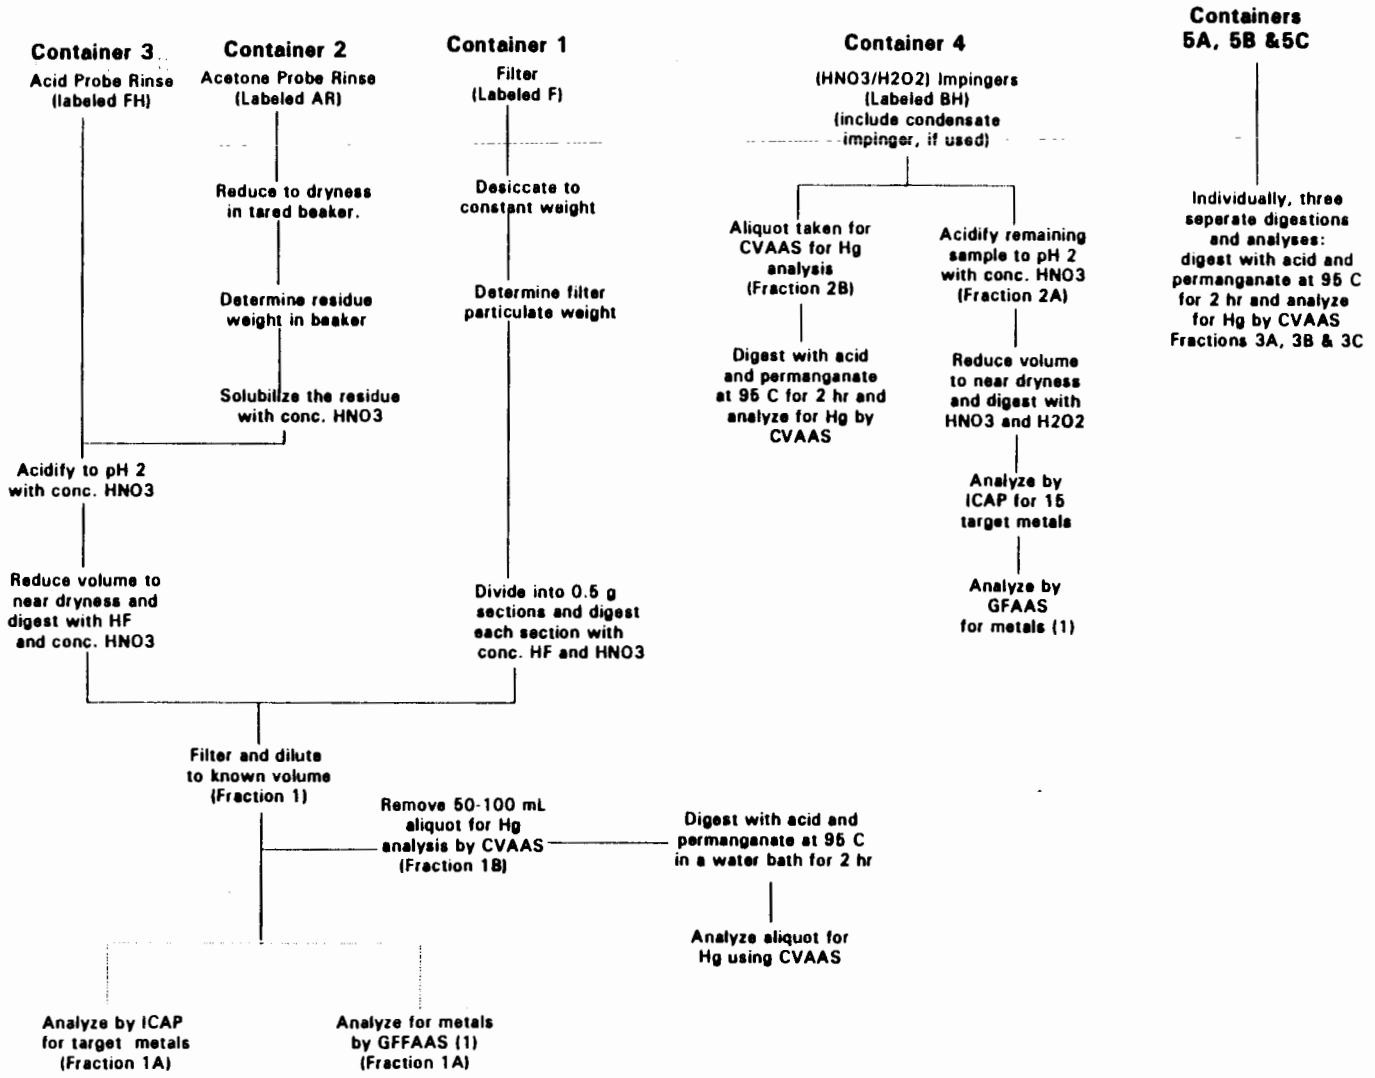

FIGURE 3. SAMPLING PREPARATION AND ANALYSIS SCHEME

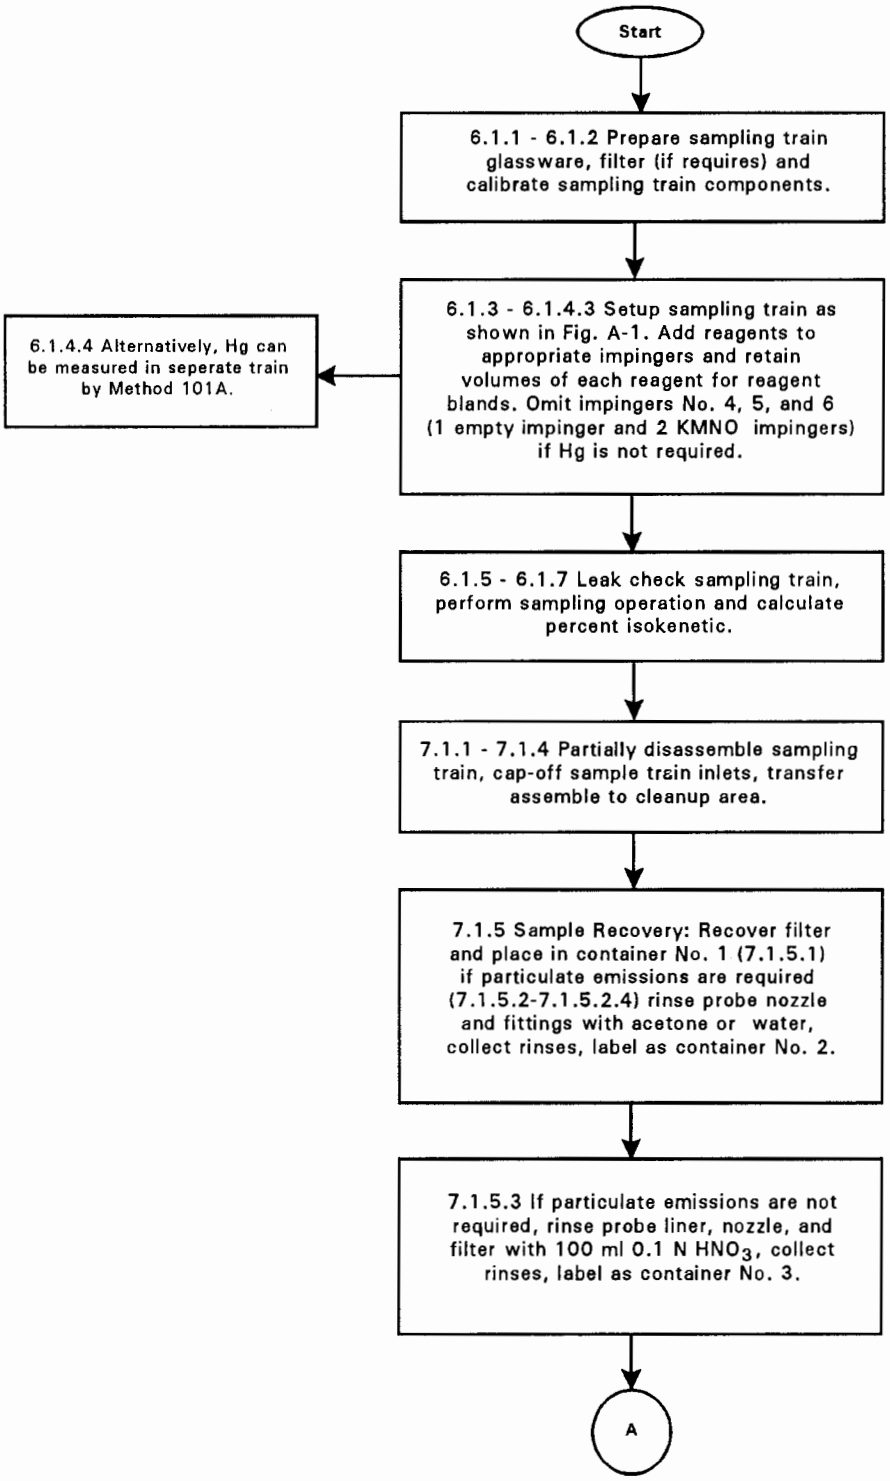
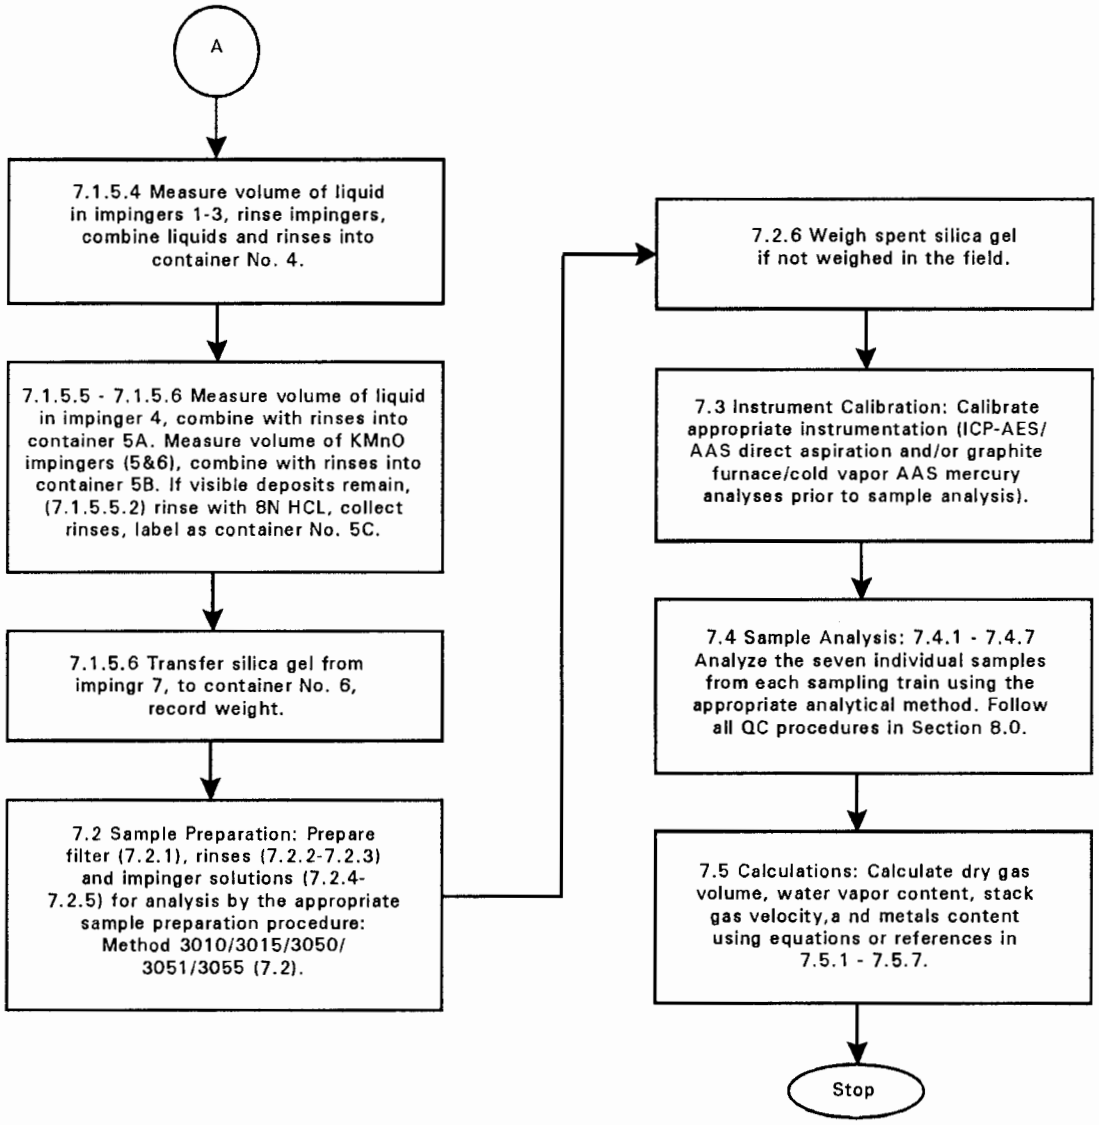


Start
6.1.1 - 6.1.2 Prepare sampling train glassware, filter (if requires) and calibrate sampling train components.
6.1.3 - 6.1.4.3 Setup sampling train as shown in Fig. A-1. Add reagents to appropriate impingers and retain volumes of each reagent for reagent blands. Omit impingers No. 4, 5, and 6 (1 empty impinger and 2 KMNO impingers) if Hg is not required.
6.1.4.4 Alternatively, Hg can be measured in seperate train by Method 101A.
6.1.5 - 6.1.7 Leak check sampling train, perform sampling operation and calculate percent isokenetic.
7.1.1 - 7.1.4 Partially disassemble sampling train, cap-off sample train inlets, transfer assemble to cleanup area.
7.1.5 Sample Recovery: Recover filter and place in container No. 1 (7.1.5.1) if particulate emissions are required (7.1.5.2-7.1.5.2.4) rinse probe nozzle and fittings with acetone or water, collect rinses, label as container No. 2.
7.1.5.3 If particulate emissions are not required, rinse probe liner, nozzle, and filter with 100 ml 0.1 N HNO_3, collect rinses, label as container No. 3.
A



A
7.1.5.4 Measure volume of liquid in impingers 1-3, rinse impingers, combine liquids and rinses into container No. 4.
7.1.5.5 - 7.1.5.6 Measure volume of liquid in impinger 4, combine with rinses into container 5A. Measure volume of KMnO impingers (5&6), combine with rinses into container 5B. If visible deposits remain, (7.1.5.5.2) rinse with 8N HCL, collect rinses, label as container No. 5C.
7.1.5.6 Transfer silica gel from impingr 7, to container No. 6, record weight.
7.2 Sample Preparation: Prepare filter (7.2.1), rinses (7.2.2-7.2.3) and impinger solutions (7.2.4-7.2.5) for analysis by the appropriate sample preparation procedure: Method 3010/3015/3050/ 3051/3055 (7.2).
7.2.6 Weigh spent silica gel if not weighed in the field.
7.3 Instrument Calibration: Calibrate appropriate instrumentation (ICP-AES/ AAS direct aspiration and/or graphite furnace/cold vapor AAS mercury analyses prior to sample analysis).
7.4 Sample Analysis: 7.4.1 - 7.4.7 Analyze the seven individual samples from each sampling train using the appropriate analytical method. Follow all QC procedures in Section 8.0.
7.5 Calculations: Calculate dry gas volume, water vapor content, stack gas velocity,a nd metals content using equations or references in 7.5.1 - 7.5.7.
Stop

METHOD 0061

DETERMINATION OF HEXAVALENT CHROMIUM EMISSIONS
FROM STATIONARY SOURCES

1.0 SCOPE AND APPLICATION

1.1 This method provides procedures for the determination of hexavalent chromium (Cr^{+6}) emissions from hazardous waste incinerators, municipal waste incinerators, municipal waste combustors, and sewage sludge incinerators. With the approval of the Administrator, this method may also be used to measure total chromium. The sampling train, constructed of Teflon components, has only been evaluated at temperatures of less than 300°F. Trains constructed of other materials, for testing at higher temperatures, are currently being evaluated.

1.2 Range: If employing a preconcentration procedure, the lower limit of the detection range can be extended to 16 nanograms per dry standard cubic meter (ng/dscm) with a 3 dscm gas sample (0.1 ppb in solution). With sample dilution, there is no upper limit. Follow your manufacturer's specific instructions on employing the preconcentration procedure for these analyses.

2.0 SUMMARY OF METHOD

2.1 For incinerators and combustors, the Cr^{+6} emissions are collected isokinetically from the source: To eliminate the possibility of Cr^{+6} reduction between the nozzle and impinger, the emission samples are collected with a recirculatory train where the impinger reagent is continuously recirculated to the nozzle. Recovery procedures include a post-sampling purge and filtration. The impinger train samples are analyzed for Cr^{+6} by an ion chromatograph equipped with a post-column reactor and a visible wavelength detector. The IC/PCR separates the Cr^{+6} as chromate ($CrO_4^{=}$) from other diphenylcarbazide reactions that occur in the post-column reactor. To increase sensitivity for trace levels of chromium, a preconcentration system may also be used in conjunction with the IC/PCR.

3.0 INTERFERENCES

3.1 Components in the sample matrix may cause Cr^{+6} to convert to trivalent chromium (Cr^{+3}) or cause Cr^{+3} to convert to Cr^{+6}. A post-sampling nitrogen purge and sample filtration are included to eliminate many of these interferences.

3.2 The chromatographic separation of Cr^{+6} using ion chromatography reduces the potential for other metals to interfere with the post-column reaction. For the IC/PCR analysis, only compounds that coelute with Cr^{+6} and affect the diphenylcarbazide reaction will cause interference.

3.3 Sample cross-contamination that can occur when high-level and low-level samples or standards are analyzed alternately is eliminated by thorough purging of the sample loop. Purging can easily be obtained by increasing the injection volume of the samples to ten times the size of the sample loop.

4.0 APPARATUS

4.1 Sampling Train: Schematics of the recirculatory sampling trains employed in this method are shown in Figures 1 and 2. The recirculatory train is readily assembled from commercially available components. All portions of the train in contact with the sample are either glass, quartz, Tygon, or Teflon, and are to be cleaned as per Section 6.0. The metering system is identical to that specified by Method 5; the sampling train consists of the following components:

4.1.1 Probe Nozzle: Glass or Teflon with a sharp, tapered leading edge. The angle of taper shall be $\leq 30^{\circ}$ and the taper shall be on the outside to preserve a constant internal diameter. The probe nozzle shall be of the button-hook or elbow design, unless otherwise specified by the Administrator. A range of nozzle sizes suitable for isokinetic sampling should be available, e.g., 0.32 to 1.27 cm (1/8 to ½ in.) -- or larger if higher volume sample trains are used -- inside diameter (ID) nozzles in increments of 0.16 cm (1/16 in.). Each nozzle shall be calibrated according to the procedures outlined in Section 7.1.1.

4.1.2 Teflon Aspirator or Pump/Sprayer Assembly (see Figures 1 and 2): Teflon aspirator capable of recirculating absorbing reagent at 50 mL/min while operating at 0.75 cfm. Alternatively, a pump/sprayer assembly may be used instead of the Teflon aspirator. A Teflon union-T is connected behind the nozzle to provide the absorbing reagent/sample gas mix; a peristaltic pump is used to recirculate the absorbing reagent at a flow rate of at least 50 mL/min. Teflon fittings, Teflon ferrules, and Teflon nuts are used to connect a glass or Teflon nozzle, recirculation line, and sample line to the Teflon aspirator or union-T. Tygon, C-flex or other suitable inert tubing for use with peristaltic pump.

4.1.3 Teflon Sample Line: Teflon, 3/8" ID, of suitable length to connect aspirator (or T-union) to first Teflon impinger.

4.1.4 Teflon Recirculation Line: Teflon, 1/4" O.D. and 1/8" I.D., of suitable length to connect first impinger to aspirator (or T-union).

4.1.5 Teflon Impingers: Four Teflon impingers; Teflon tubes and fittings, such as made by Savillex*, can be used to construct impingers 2" diameter by 12" long, with vacuum-tight 3/8" O.D. Teflon compression fittings. Alternatively, standard glass impingers that have been Teflon-lined, with Teflon stems and U-tubes, may be used. Inlet fittings on impinger top to be bored through to accept 3/8" O.D. tubing as impinger stem. The second and third 3/8" OD Teflon stem has a 1/4" OD Teflon tube, 2" long, inserted at its impinger stem should extend to 2" from impinger bottom, high enough in the impinger reagent to prevent air from entering recirculating line; the second and third impinger stems should extend to ½" from impinger bottom. The first impinger should include a 1/4" O.D. Teflon compression fitting for recirculation line. The fourth impinger serves as a knockout impinger to trap solution carried over from the previous impingers.

NOTE: Mention of trade names or specific product does not constitute endorsement by the Environmental Protection Agency.

4.1.6 Glass Impinger: Silica gel impinger, Vacuum-tight impingers, capable of containing 400 g. of silica gel, with compatible fittings. The silica gel impinger will have a modified stem (½" ID at tip of stem).

4.1.7 Thermometer, (identical to that specified by Method 5) at the outlet of the silica gel impinger, to monitor the exit temperature of the gas.

4.1.8 Metering System, Barometer, and Gas Density Determinations Equipment: Same as Method 0010.

4.2 Sample Recovery: Clean all items for sample handling or storage with 10% nitric acid solution by soaking, where possible, and rinse thoroughly with reagent water before use.

4.2.1 Nitrogen Purge Line: Inert tubing and fittings capable of delivering 0 to 1 scf/min (continuously adjustable) of nitrogen gas to the impinger train from a standard gas cylinder (see Figure 3).

4.2.2 Wash Bottles: Two polyethylene wash bottles, for reagent water-nitric rinse solution.

4.2.3 Sample Storage Containers: Polyethylene, with leak-free screw cap, 500-mL or 1000-mL.

4.2.4 1000-mL Graduated Cylinder and Balance.

4.2.5 Plastic Storage Containers: Air tight containers to store silica gel.

4.2.6 Funnel and Rubber Policeman: To aid in transfer of silica gel from impinger to storage container; not necessary if silica gel is weighed directly in the impinger.

4.3 Sample Preparation for Analysis: Sample preparation prior to analysis includes purging the sample train immediately following the sample run, and filtering the recovered sample to remove particulate matter immediately following recovery.

4.3.1 Beakers, Funnels, Volumetric Flasks, Volumetric Pipets, and Graduated Cylinders: Assorted sizes, Teflon or glass, for preparation of samples, sample dilution, and preparation of calibration standards. Prepare initially following procedure described in Section 5.1.3 and rinse between use with 0.1 M HNO_3 and reagent water.

4.3.2 Filtration Apparatus: Teflon, or equivalent, for filtering samples, and Teflon filter holder. Teflon impinger components have been found to be satisfactory as a sample reservoir for pressure filtration using nitrogen.

4.4 Ion Chromatograph: Refer to Section 4.0 of Method 7199 for instrument and equipment specifications.

4.4.1 Preconcentrator: System in-line with the ion chromatograph.

OR

4.5 Sample preconcentration system: A high performance ion chromatograph (HPIC) non-metallic column with acceptable anion retention characteristics and sample loading rates as described in the analytical method.

5.0 REAGENTS

5.1 All inorganic reagents should conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. All prepared reagents should be checked by IC/PCR analysis for Cr^{+6} to assure that contamination is below the analytical detection limit for direct injection or, if selected, preconcentration. If total chromium is also to be determined, the reagents should also be checked by the analytical technique selected to assure that contamination is below the analytical detection limit.

5.2 Sampling.

5.2.1 Reagent water: Reagent water shall be interferences free. All references to water in the method refer to reagent water unless otherwise specified. A definition of reagent water can be found in Chapter One.

5.2.2 Potassium Hydroxide, 0.1 M: Add 5.6 gm of KOH(s) to approximately 900 mL of reagent water and let dissolve. Dilute to 1000 mL with reagent water. A brief unpublished EPA study showed sources of 2N KOH with concentrations of hexavalent chromium ranging from 1.02 ppb to 7.86 ppb. If the lowest detection limit is needed for a given project, an effort should be made to obtain KOH with the minimum possible contamination. Initial attempts to develop an acceptable purification procedure have been unsuccessful.

NOTE: At sources with high concentrations of acids and/or SO_2, the concentration of KOH should be increased to 0.5 M to insure that the pH of the solution is above 8.5 after sampling.

5.2.3 Silica Gel and Crushed Ice: Same as Method 5.

5.3 Sample Recovery: The reagents used in sample recovery are as follows:

5.3.1 Water: Same as Section 5.2.1.

5.3.2 Nitric Acid, 0.1 M: Add 6.3 mL of concentrated HNO_3 (70 percent) to a graduated cylinder containing approximately 900 mL of reagent water. Dilute to 1000 mL with reagent water, and mix well.

5.3.3 pH Indicator Strip: pH indicator capable of determining pH of solution between the pH range of 7 and 12, at 0.5 pH intervals.

5.4 Sample Preparation

5.4.1 Reagent water: Same as Section 5.2.1.

5.4.2 Nitric Acid, 0.1 M: Same as Section 5.3.2.

5.4.3 Filters: Acetate membrane, or equivalent, filters with 0.45 micrometer or smaller pore size to remove insoluble material.

5.5 Analysis

5.5.1 Refer to Section 5.0 of Method 7199 for instruction on preparation of analytical reagents.

5.6 Performance Audit Sample: A performance audit sample should be analyzed in conjunction with the samples. The audit sample should be prepared in a suitable sample matrix at a concentration similar to the actual field samples.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Refer to Section 6.0 of Method 7199 for the proper procedures when collecting, preserving, and handling samples.

6.2 If sample preconcentration is used, dropwise addition of the ammonium sulfate/ammonium hydroxide buffer may not be appropriate, since the added sulfate may lead to premature overloading of the column.

6.3 A holding time of 14 days is appropriate for samples collected by Method 0061, even though Method 7199 has a 24 hr. hold for other samples. The Method 0061 samples are already stabilized in an alkaline solution, as opposed to many samples from other media which may be submitted for analysis in an unstable condition. An optional method of demonstrating stability is to field spike some of the sample matrix with known amounts of Cr^{+6} and determine recovery.

7.0 PROCEDURE

CAUTION: Wear Safety Glasses At All Times During This Test Method.

7.1 Sampling: The complexity of this method is such that to obtain reliable results, testers should be trained and experienced with test procedures.

7.1.1 Sample Train Calibration: Calibrate the sample train components according to the indicated sections of Method 5: Probe Nozzle; Pitot Tube; Metering System; Temperature Gauges; Leak-Check of the Metering System; and Barometer.

7.1.2 Pretest Preparation: All components shall be maintained and calibrated according to the procedures described in APTD-0576, unless otherwise specified herein. Rinse all sample train components from the glass nozzle up to the silica gel impinger and sample containers with hot tap water followed by washing with hot soapy water. Next, rinse the train components and sample containers three times with tap water followed by three rinses with reagent water. All the components and container should then be soaked overnight, or a minimum of 4 hours, in a 10 % (v/v) nitric acid solution, then rinsed three times with reagent water. Allow the components to air dry prior to covering all openings with Parafilm, or equivalent.

7.1.3 Preliminary Determinations: Same as Method 5, Section 4.

7.1.4 Preparation of Sampling Train: Measure 300 mL of 0.1 M KOH into a graduated cylinder (or tare-weighed precleaned polyethylene container). Place approximately 140 mL of the 0.1 M KOH reagent in the first Teflon impinger. Split the rest of the 0.1 M KOH between the second and third Teflon impingers. The next Teflon impinger is left dry. Place a preweighed 200-to 400-g portion of indicating silica gel in the final glass impinger. (For sampling periods in excess of two hours, or for high moisture sites, 400-g of silica gel is recommended). Retain reagent blanks of the 0.1 M KOH equal to the volumes used with the field samples.

7.1.5 Leak-Check Procedures: Follow the leak-check procedures given in Method 5: Pretest Leak-Check, Leak-Checks During the Sample Run, and Post-Test Leak-Checks.

7.1.6 Sampling Train Operation: Follow the procedures given in Method 5, Section 4.1.5. If the sampling train should be iced down with water and ice to insure heat transfer with the Teflon impingers.

NOTE: If the gas to be sampled is above 200°F, it may be necessary to wrap three or four feet of the Teflon sample and recirculating lines inside the ice bath to keep the recirculated reagent cool enough so it does not turn to steam.

For each run, record the data required on a data sheet such as the one shown in Figure 5-2 of Method 5. At the end of the sampling run, determine the pH of the reagent in the first impinger using a pH indicator strip. The pH of the solution shall be greater than 8.5. If the pH is not above 8.5, discard the solution. Prepare a clean sampling train as described above using 0.5 M KOH instead of 0.1 M KOH, as noted in Section 5.2.2. For use of the train at relatively high acid sources, it may be necessary to employ extra caustic, stronger caustic, shorter sampling times, and closer monitoring of pH. See the references for suggestions. Leak-check and operate the sampling train as described above. Repeat the sampling run.

7.1.7 Calculation of Percent Isokinetic: Same as Method 5, Section 4.

7.2 Post-test Nitrogen Purge. The nitrogen purge is used as a safeguard against the conversion of hexavalent chromium to the trivalent oxidation state. The purge is effective in the removal of SO_2 from the impinger contents. Attach the nitrogen purge line to the input of the impinger train. Check to insure the output of the impinger train is open, and that the recirculating line is capped off. Open the nitrogen gas flow slowly and adjust the delivery rate to 10 L/min. Check the recirculating line to insure that the pressure is not forcing the impinger reagent out through this line. Continue the purge under these conditions for one-half hour periodically checking the flow rate.

7.3 Sample Recovery: Begin cleanup procedures as soon as the train assembly has been purged at the end of the sampling run. The probe assembly may be disconnected from the sample train prior to sample purging. The probe assembly should be allowed to cool prior to sample recovery. Disconnect the umbilical cord from the sample train. When the probe assembly can be safely handled, wipe off all external particulate matter near the tip of the nozzle, and cap the nozzle prior to transporting the sample train to a clean up area that is clean and protected from the wind and other potential causes of contamination or loss of sample. Inspect the train before and during disassembly and note any abnormal conditions.

7.3.1 Container No. 1 (Impingers 1 through 3): Disconnect the first impinger from the second impinger and disconnect the recirculation line form the aspirator or peristaltic pump. Drain the Teflon impingers into a precleaned graduated cylinder or tare-weighted precleaned polyethylene sample container and measure the volume of the liquid to within 1 mL or 1 gm. Record the volume of liquid present as this information is required to calculate the moisture content of the flue gas sample. If necessary, transfer the sample from the graduated cylinder to a precleaned polyethylene sample container. With reagent water, rinse four times the insides of the glass nozzle, the aspirator, the sample and recirculation lines, the impingers, and the connecting tubing, and combine the rinses with the impinger solution in the sample container.

7.3.2 Container No. 2 (HNO_3 rinse optional for total chromium): With 0.1 M HNO3, rinse three times the entire train assembly, from the nozzle to the fourth impinger, and combine the rinses into a separate precleaned polyethylene sample container for possible total chromium analysis. Repeat the rinse procedure a final time with reagent water, and discard the water rinses. Mark the height of the fluid level on the container or, alternatively if a balance is available, weigh the container and record the weight to permit determination of any leakage during transport. Label the container clearly to identify its contents.

7.3.3 Container No. 3 (Silica Gel): Note the color of the indicating silica gel to determine if it has been completely spent. Quantitatively transfer the silica gel from its impinger to the original container, and seal the container. A funnel and a rubber policeman may be used to aid in the transfer. The small amount of particulate that may adhere to the impinger wall need not be removed. Do not use water or other liquids to transfer the silica gel. Alternatively, if a balance is available in the field, record the weight of the spent silica gel (or the silica gel plus impinger) to the nearest 0.5 g.

7.3.4 Container No 4 (0.1 M KOH Blank): Once during each field test, place a volume of reagent equal to the volume placed in the sample train into a precleaned polyethylene sample container, and seal the container. Mark the height of the fluid level on the container or, alternatively if a balance is available, weigh the container and record the weight to permit determination of any leakage during transport. Label the container clearly to identify its contents.

7.3.5 Container No. 5 (Reagent Water Blank): Once during each field test, place a volume of reagent water equal to the volume employed to rinse the sample train into a precleaned polyethylene sample container, and seal the container. Mark the height of the fluid level on the container or, alternatively if a balance is available, weigh the container and record the weight to permit determination of any leakage during transport. Label the container clearly to identify its contents.

7.3.6 Container No. 6 (0.1 M HNO_3 Blank): Once during each field test if total chromium is to be determined, place a volume of 0.1 M HNO_3 reagent equal to the volume employed to rinse the sample train into a precleaned polyethylene sample container, and seal the container. Mark the height of the fluid level on the container or, alternatively if a balance is available, weigh the container and record the weight to permit determination of any leakage during transport. Label the container clearly to identify its contents.

7.4 Sample Preparation: For determination of Cr^{+6}, the sample should be filtered immediately following recovery to remove any insoluble matter. Nitrogen gas may be used as a pressure assist to the filtration process (see Figure 4). Filter the entire impinger sample through a 0.45 micrometer acetate filter (or equivalent), and collect the filtrate in a 1000-mL graduated cylinder. Rinse the sample container with reagent water three separate times and pass these rinses through the filter, and add the rinses to the sample filtrate. Rinse the Teflon reservoir with reagent water three separate times and pass these rinses through the filter, and add the rinses to the sample. Determine the final volume of the filtrate and rinses and return them to the rinsed polyethylene sample container. Label the container clearly to identify its contents. Rinse the Teflon reservoir once with 0.1 M HNO_3 and once with reagent water and discard these rinses. If total chromium is to be determined, quantitatively recover the filter and residue and place them in a vial. (The acetate filter may be digested with 5 mL of 70% nitric acid; this digestion solution may then be diluted with reagent water for total chromium analysis by inductively coupled plasma atomic emission or graphite furnace atomic absorption spectrometric methods.)

NOTE: If the source has a large amount of particulate in the effluent stream, testing teams may wish to filter the sample twice, once through a 2-5 micrometer filter, then through the 0.45 micrometer filter.

7.4.1 Container No. 2 (HNO_3 rinse, optional for total chromium): This sample shall be analyzed in accordance with the selected procedure for total chromium analysis. At a minimum, the sample should be subjected to a digestion procedure sufficient to solubilize all chromium present.

7.4.2 Container 3 (Silica Gel): Weigh the spent silica gel to the nearest 0.5 g using a balance. (This step may be conducted in the field.)

7.5 Sample Analysis: The Cr^{+6} content of the sample filtrate is determined by ion chromatography coupled with a post column reactor (IC/PCR). Method 7199 should be used for this analysis. To increase sensitivity for trace levels of chromium, a preconcentration system is also used in conjunction with the IC/PCR. Prior to preconcentration and/or analysis, all field samples will be filtered through a 0.45 µm filter. This filtration should be conducted just prior to sample injection/analysis.

7.5.1 Preconcentration: The preconcentration is accomplished by selectively retaining the analyte on a solid absorbent, followed by removal of the analyte from the absorbent.

Refer to Section 7.0 of Method 7199 for the proper sample analysis protocol.

7.6 Calculations

7.6.1 Dry Gas Volume: Using the data form the test, calculate $V_{m(std)}$, the dry gas sample volume at standard conditions as outlined in Method 5.

7.6.2 Volume of Water Vapor and Moisture Content: Using the data form the test, calculate $V_{w(std)}$ and B_{ws}, the volume of water vapor and the moisture content of the stack gas, respectively, using Equations 5-2 and 5-3 of Method 5.

7.6.3 Stack Gas Velocity: Using the data form the test and Equations 2-9 of Method 2, calculate the average stack gas velocity.

7.6.4 Total µg Cr^{+6} Per Sample. Calculate as described below:

$$m = (S-B) \times V_{ls} \times d$$

Where:

m = Mass of Cr^{+6} in the sample, µg,
S = Concentration of Sample, µg Cr^{+6}/mL,
B = Concentration of blank, µg Cr^{+6}/mL,
V_{ls} = Volume of sample after filtration, mL, and,
d = Dilution factor (1 if not diluted).

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for the appropriate quality control procedures.

9.0 METHOD PERFORMANCE

9.1 Sensitivity: A minimum detection limit of 8 ng/dscm with a 3 dscm gas sample can be achieved by preconcentration (0.05 ppb in solution). Follow instrument manufacturers instructions for sample preconcentration.

9.2 Precision: The precision of the IC/PCR with sample preconcentration is 5 to 10 percent. The overall precision for sewage sludge incinerators emitting 120 ng/dscm of Cr^{+6} and 3.5 ug/dscm of total chromium is 25% and 9% for Cr^{+6} and total chromium, respectively; for hazardous waste incinerators emitting 300 ng/dscm of Cr^{+6} it is 20%.

9.3 Refer to Section 9.0 of Method 7199 for additional analytical method performance information.

METHOD 0100

SAMPLING FOR FORMALDEHYDE AND OTHER CARBONYL COMPOUNDS IN INDOOR AIR

1.0 SCOPE AND APPLICATION

1.1 This method provides procedures for the sampling of various carbonyl compounds in indoor air by derivatization with 2,4-dinitrophenylhydrazine (DNPH) in a silica gel cartridge. The method may be used in conjunction with Method 8315. The following compounds may be sampled by this method:

Compound Name	CAS No.[a]
Acetaldehyde	75-07-0
Acetone	67-64-1
Acrolein	107-02-8
Benzaldehyde	100-52-7
Butyraldehyde	123-72-8
Crotonaldehyde	123-73-9
2,5-Dimethylbenzaldehyde	5779-94-2
Formaldehyde	50-00-0
Hexanal	66-25-1
Isovaleraldehyde	590-86-3
Propionaldehyde	123-38-6
m-Tolualdehyde	620-23-5
o-Tolualdehyde	529-20-4
p-Tolualdehyde	104-87-0
Valeraldehyde	110-62-3

[a] Chemical Abstract Service Registry Number

1.2 This method is restricted to use by, or under the close supervision of, trained analytical personnel experienced in sampling organic compounds in air. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 A known volume of indoor air is drawn through a prepacked silica gel cartridge coated with acidified 2,4-dinitrophenylhydrazine (DNPH), at a predetermined sampling rate for an appropriate period of time. After sampling, the sample cartridges are capped and placed in borosilicate glass tubes with polypropylene caps and placed in cold storage until analysis. The compounds of interest may then be eluted from the cartridge with acetonitrile from a plastic syringe reservoir into a graduated test tube or a volumetric flask. The eluate is then topped to known volume and refrigerated until analysis. Analysis may be done High Performance Liquid Chromatography (HPLC), Method 8315, with an ultraviolet (UV/Vis) detector at 360 nm.

3.0 INTERFERENCES

3.1 Solvents, reagents, glassware and other sample processing may yield discrete artifacts and/or elevated baselines causing misinterpretation of the chromatograms. All of these materials must be demonstrated to be free from interferences, under the conditions of analysis, by analyzing method blanks.

3.1.1 Glassware and plasticware must be scrupulously cleaned. Clean all glassware and plasticware as soon as possible after use by rinsing with the last solvent used in it. This should be followed by detergent washing with hot water and rinsing with tap water, organic-free reagent water, and aldehyde-free acetonitrile. After cleaning, glassware and plasticware should be stored in a clean environment to prevent any accumulation of dust or other contaminants.

3.1.2 High purity reagents and solvents should be used to minimize interference problems. Purification of solvents by distillation in all-glass systems may be necessary.

3.1.3 Polyethylene gloves should be worn when handling the silica gel cartridges to reduce the possibility of contamination.

3.2 Contamination of the DNPH reagent is a frequently encountered problem. Formaldehyde, acetone, and 2,4-dinitroanaline (a decomposition product of DNPH) may be significant analytical impurities in the DNPH reagent at high concentrations. The DNPH must be purified by multiple recrystallizations in UV-grade acetonitrile. Recrystallization is accomplished, at 40-60°C, by slow evaporation of the solvent to maximize crystal size. The purified DNPH crystals are stored under UV-grade acetonitrile until use. Impurity levels of carbonyl compounds in the DNPH are determined prior to the analysis of the samples and should be less than 0.025 µg/mL. Refer to Sec. 5.9 for a recrystallization procedure.

3.3 Ozone Interferences - Ozone at high concentration has been shown to interfere negatively by reacting with both DNPH and its hydrazone derivatives in the cartridge (Ref. 6).

3.3.1 The extent of interference depends on the temporal variations of both the ozone and the carbonyl compounds during sampling. The presence of ozone in the sample stream is readily inferred from the appearance of new compounds with retention times shorter than that of the hydrazone of formaldehyde. Figure 1 shows chromatograms of samples of a formaldehyde-spiked air stream with and without ozone.

3.3.2 The most direct solution to the ozone interference is to remove the ozone before the sample stream reaches the cartridge. This process entails constructing an ozone denuder or scrubber and placing it on the front of the cartridge. The denuder is constructed out of 1 m of 0.64 cm OD copper tubing, which is filled with a saturated solution of KI water, allowed to stand for approximately 5 minutes, and dried with a stream of clean air or nitrogen for about 1 hour. The capacity of the ozone denuder as described is about 10,000 ppb/hour of ozone. Test aldehydes that were dynamically spiked into an ambient sample air stream passed through the denuder with virtually no losses.

3.4 Samples may be contaminated during shipment or storage by diffusion of volatile organics through the sample bottle septum seal. Field reagent blanks must be analyzed to determine when sampling and storage procedures have caused the contamination.

3.5 Matrix interferences may be caused by contaminants acquired by the sampling process. The extent of matrix interferences will vary considerably from source to source, depending upon the nature and diversity of the matrix being sampled. If significant interferences occur due to organic compounds that have the same retention time, altering the separation conditions by using alternative HPLC columns or mobile phase conditions may resolve the problem.

4.0 APPARATUS AND MATERIALS

4.1 Sampling Equipment

4.1.1 Sampling System - capable of accurately and precisely sampling 0.10 to 1.50 L/min of indoor air. The procedures given here assume use of a dry meter-equipped sampling system operated at flow rates of at least 0.5 L/min.

NOTE: A normal pressure drop through the sample cartridge approaches 19 kPa at a sampling rate of 1.5 L/min.

4.1.2 Thermometer and Barometer - to record indoor conditions at the time of sampling.

4.1.3 Stopwatch - to time sampling.

4.1.4 Rotameters - to allow observation of the flow rate without interruption of the sampling process.

4.1.5 Mass Flowmeters and Mass Flow Controllers - for metering and setting the air flow rate through the sample cartridge (0.50 to 1.20 L/min). These are necessary because cartridges have a high pressure drop and, at maximum flow rates, the cartridge behaves like a "critical orifice" and can display a flow rate drop over an extended sampling period (generally less than 5% over a 24 hour period).

4.1.6 Fittings and Plugs (Luer-Lok or equivalent) - to connect cartridges to the sampling system and to cap prepared cartridges.

4.1.7 Heated Probe - necessary when the temperature of sampled air is below 60°F, to insure effective collection of formaldehyde as a hydrazone.

4.1.8 Silica Gel Cartridges - chromatographic grade, 2 cm x 1.5 cm ID, with Luer-Lok type fittings on each end, for manual application of acidified DNPH coating (Sep-PAK from Waters Associates or equivalent). Commercially pre-packaged pre-coated cartridges are also available (Thermosorb/F cartridges from Thermedics Inc. and LpDNPH cartridges from Supelco, Inc. are examples).

4.2 Glassware

4.2.1 Volumetric Flasks - various sizes, 5 to 2000 mL.

4.2.2 Pipets - various sizes, 1 to 50 mL.

4.2.3 Sample Vials.

4.2.4 Borosilicate glass culture tubes (20 x 125 mm) with polypropylene screw caps - for transporting coated cartridges.

4.3 Liquid Syringes (polypropylene are adequate) - 10 mL, used to prepare DNPH-coated cartridges.

4.4 Syringe Rack - made of an aluminum plate with adjustable legs on all four corners. Circular holes of a diameter slightly larger than the diameter of the 10 mL syringes are drilled through the plate to allow batch processing of cartridges for cleaning, coating, and sample elution. A 0.16 x 36 x 53 cm plate with 45 holes in a 5x9 matrix is recommended. See Figure 2.

4.5 Cartridge Drying Manifold - has multiple standard male fittings (Luer-Lok or equivalent). See Figure 2.

4.6 Repetitive Dispensing Pipets - positive displacement, 0 to 10 mL range, with 1 L reagent bottles (Lab-Industries or equivalent).

4.7 Polyethylene Gloves - used to handle silica gel cartridges.

4.8 Sample Vial Holder - Friction-top metal can (e.g., 4 L paint can) or a styrofoam box lined with either polyethylene air bubble padding or granular charcoal to cushion the samples.

4.9 Soap Bubble Flowmeter or Calibrated Wet Test Meter - for calibrating the sampling flow rate.

4.10 Melting Point Apparatus (optional)

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Organic-free reagent water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One.

5.3 Nitrogen gas, N_2 - high purity grade.

5.4 Acetonitrile, CH_3CN - UV grade.

5.5 Formaldehyde, CH_2O - ACS certified or assayed 36.5% solution (W/W).

5.6 Aldehydes and Ketones - analytical grade, used for preparation of DNPH derivative standards of target analytes other than formaldehyde. See list on page 1 for possible target analytes.

5.7 Perchloric Acid, $HClO_4$ - analytical grade.

CAUTION: Concentrated (69%) perchloric acid is a very strong oxidizing agent and presents a serious explosion hazard when combined with organic chemicals or materials. Any perchloric acid to be used in the preparation of DNPH, as per Sec. 5.9, must first be diluted with water to 3.8M as required in Sec. 5.9.5.

5.8 Hydrochloric Acid, HCl - analytical grade.

5.9 2,4-Dinitrophenylhydrazine (DNPH), $C_6H_6N_4O_4$ - recrystallize at least twice with UV grade acetonitrile using the following procedure:

NOTE: This procedure should be performed under a properly ventilated hood. Inhalation of acetonitrile can result in nose and throat irritation (brief exposure at 500 ppm) or more serious effects at higher concentration and/or longer exposures.

5.9.1 Prepare a saturated solution of DNPH by boiling excess DNPH in 200 mL of acetonitrile for approximately 1 hour.

5.9.2 After 1 hour, remove and transfer the supernatant to a covered beaker on a hot plate and allow gradual cooling to 40 to 60°C. Maintain this temperature range until 95% of the solvent has evaporated leaving crystals.

5.9.3 Decant the solution to waste and rinse the remaining crystals twice with three times their apparent volume of acetonitrile.

5.9.4 Transfer the crystals to a clean beaker, add 200 mL of acetonitrile, heat to boiling, and again let the crystals grow slowly at 40 to 60°C until 95% of the solvent has evaporated. Repeat the rinsing process as in Sec. 5.9.3.

5.9.5 Take an aliquot of the second rinse, dilute 10 times with acetonitrile, acidify with 1 mL of 3.8 M perchloric acid per 100 mL of DNPH solution, and analyze by HPLC Method 8315). An acceptable impurity level is less than 0.025 mg/L of formaldehyde in recrystallized DNPH reagent or below the sensitivity (ppb, v/v) level indicated in Table 1 for the anticipated sample volume.

5.9.6 If the impurity concentration is not satisfactory, pipet off the solution to waste, repeat the recrystallization as in Sec. 5.9.4 but rinse with two 25 mL portions of acetonitrile. Prep and analyze the second rinse as in Sec. 5.9.5.

5.9.7 When the impurity concentration is satisfactory, place the crystals in an all-glass reagent bottle, add another 25 mL of acetonitrile, stopper, and shake the bottle. Use clean pipets when removing the saturated DNPH stock solution to reduce the possibility of contamination of the solution. Maintain only a minimum volume of the saturated solution adequate for day to day operation to minimize waste of the purified reagent.

5.10 Refer to the determinative method (Method 8315) for procedures regarding the preparation of DNPH derivatives, standards of the derivatives, and calibration standards for HPLC analysis. All standard solutions should be stored at about 4°C in a glass vial with a Teflon®-lined cap, with minimum headspace, and in the dark. They should be stable for about 6 weeks. All standards should be checked frequently for signs of degradation or evaporation, especially just prior to preparing calibration standards from them.

5.11 Preparation of DNPH-Coated Sep-PAK Cartridges (if pre-packaged pre-coated cartridges, as in Sec. 4.1.8, are not used)

NOTE: This procedure must be performed in an atmosphere with a very low aldehyde background. The atmosphere above the acidified solution should preferably be filtered through a DNPH-coated silica gel cartridge to minimize contamination from laboratory air. All glassware and plasticware must be scrupulously cleaned and rinsed with deionized water and aldehyde free acetonitrile. Contact of reagents with laboratory air must be minimized. Polyethylene gloves must be worn when handling the cartridges.

5.11.1 DNPH Coating Solution

5.11.1.1 Pipet 30 mL of saturated DNPH stock solution into a 1000 mL volumetric flask, add 500 mL acetonitrile, and acidify with 1.0 mL of concentrated HCl.

5.11.1.2 Shake solution and dilute to volume with acetonitrile. Stopper the flask, invert, and shake several times until the solution is homogeneous. Transfer the acidified solution to a reagent bottle equipped with a 0 to 10 mL range repetitive pipet dispenser. Prime the dispenser and slowly dispense 10 to 20 mL to waste.

5.11.1.3 Dispense an aliquot solution to a sample vial, and check the impurity level of the acidified solution by HPLC according to Sec. 7.2.

5.11.1.4 The impurity concentration should be less than 0.025 µg/mL formaldehyde, similar to that in the DNPH stock solution.

5.11.2 Coating of Sep-PAK Cartridges

5.11.2.1 Open the Sep-PAK package, connect the short end to a 10 mL syringe and place it in the syringe rack. The syringe rack used for coating and drying the sample cartridges is illustrated in Figures 2(a) and 2(b).

5.11.2.2 Using a positive displacement, repetitive pipet, add 10 mL of acetonitrile to each of the syringes.

5.11.2.3 Let the liquid drain to waste by gravity. Remove any air bubbles that may be trapped between the syringe and the silica cartridge by displacing them with the acetonitrile in the syringe.

5.11.2.4 Once the effluent flow at the outlet of the cartridge has stopped, dispense 7 mL of the acidified DNPH coating reagent into each of the syringes using the repetitive pipet dispenser.

5.11.2.5 Let the coating reagent drain by gravity through the cartridge until flow at the other end of the cartridge stops.

5.11.2.6 Wipe the excess liquid at the outlet of each of the cartridges with clean tissue paper.

5.11.2.7 Assemble a drying manifold as shown in Figure 2(b). This contains a previously prepared, DNPH-coated, cartridge at each of the exit ports (e.g., these

scrubber or "guard cartridges" can be prepared by drying a few of the newly coated cartridges as per the following sections, and "sacrificing" these few to assure the purity of the rest). The "guard cartridges" serve to remove traces of formaldehyde that may be present in the nitrogen gas supply.

5.11.2.8 Insert cartridge connectors (flared at both ends, 0.64 cm OD x 2.5 cm Teflon® FEP tubing with ID slightly smaller than the OD of the cartridge port) onto the long end of the scrubber cartridges.

5.11.2.9 Remove the cartridges from the syringes and connect the short ends of the cartridges to the open end of the cartridge connectors already attached to the scrubber cartridges.

5.11.2.10 Pass nitrogen through each of the cartridges at about 300 to 400 mL/min.

5.11.2.11 Rinse the exterior surfaces and outlet end of the cartridges with acetonitrile using a Pasteur pipet.

5.11.2.12 After 15 minutes, stop the flow of nitrogen, wipe the cartridge exterior free of rinse acetonitrile and remove the dried cartridges.

5.11.2.13 Plug both ends of the coated cartridge with standard polypropylene Luer-Lok male plugs and place the plugged cartridge in a borosilicate glass culture tube with polypropylene screw caps.

5.11.2.14 Put a serial number and a lot number label on each of the individual cartridge glass storage containers and refrigerate the prepared lot until use. Cartridges will maintain their integrity for up to 90 days stored in refrigerated, capped culture tubes.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Assemble the sampling system, and ensure that the pump is capable of constant flow rate throughout the sampling period. The coated cartridges can be used as direct probes and traps for sampling indoor air when the temperature is above 60°F.

6.1.1 If the temperature in below 60°F, use the heated probe, mentioned in Sec. 4.1.7, to warm the air entering the sampling equipment.

6.1.2 If necessary, add an ozone denuder (see Sec. 3.3).

6.2 Before sample collection, check the system for leaks. Plug the input (short end) of the cartridge so no flow is indicated at the output end of the pump. The mass flowmeter should not indicate any air flow through the sampling apparatus.

6.3 Install the entire assembly (including a "dummy" sampling cartridge) and check the flow rate at a value near the desired rate. In general, flow rates of 500-1200 mL/min should be employed. The total moles of carbonyl in the volume of air sampled should not exceed that of the DNPH (2 mg or 0.01 mmole/cartridge). In general, a safe estimate of the sample size should be approximately 75% of the DNPH loading of the cartridge (approximately 200 µg as HCHO). Generally, calibration

is accomplished using a soap bubble flowmeter or calibrated wet test meter connected to the flow exit, assuming the system is sealed.

NOTE: ASTM Method D3686 describes an appropriate calibration scheme that does not require a sealed flow system downstream of the pump.

6.4 Ideally, a dry gas meter is included in the system to measure and record total flow. If a dry gas meter is not available, the operator must measure and record the sampling flow rate at the beginning and end of the sampling period to determine sample volume. If the sampling period exceeds two hours, the flow rate should be measured at intermediate points during the sampling period. Include a rotameter to allow observation of the flow rate without interruption of the sampling process.

6.5 Before sampling, remove the glass culture tube from the friction-top metal can or styrofoam box. Let the cartridge warm to room temperature in the glass tube before connecting it to the sample train.

6.6 Using polyethylene gloves, remove the coated cartridge from the glass tube and connect it to the sampling system with a Luer adapter fitting. Seal the glass tube for later use, and connect the cartridge to the sampling train so that the short end becomes the sample inlet.

6.7 Turn the sampler on, record the start time, and adjust the flow to the desired rate. A typical flow rate through one cartridge is 1.0 L/min and 0.8 L/min for two cartridges in tandem.

6.8 Operate the sampler for the desired period, with periodic recording of the sampling variables such as sample flow rate, pressure, and temperature.

6.9 At the end of the sampling period, stop the flow and record the stop time. If a dry gas meter or equivalent is not used, the flow rate must be checked just before stopping the flow. The average sample flow rate may be calculated using the equation in Sec. 9.1.1. If the flow rate at the beginning and end of the sampling period differ by more than 15%, the sample should be marked as suspect.

6.10 Immediately after sampling, remove the cartridge (using polyethylene gloves) from the sampling system, cap with Luer end plugs, and place it back in the original labeled glass culture tube. Cap the culture tube, seal it with Teflon® tape, label the tube, and place it in a friction-top can containing 2-5 cm of granular charcoal or styrofoam box with appropriate padding. Refrigerate the culture tubes until analysis. The refrigeration period prior to analysis should not exceed 30 days.

NOTE: If samples are to be shipped to a central laboratory for analysis, the duration of the non-refrigerated period should be kept to a minimum, preferably less than two days.

6.11 Use the equations found in Secs. 9.1.2 and 9.1.3 to calculate the total volume of air sampled and the total volume of air sampled at standard conditions.

7.0 SAMPLE RECOVERY

7.1 The samples are returned to the laboratory in a friction-top can containing 2 to 5 cm of granular charcoal and stored in a refrigerator until analysis. Alternatively, the samples may also be

stored alone in their individual glass containers. The time between sampling and analysis should not exceed 30 days.

7.2 Refer to the determinative method (Method 8315) for procedures regarding desorption of the sample from the cartridge and HPLC analysis preparation.

8.0 CALIBRATIONS

8.1 Refer to Sec. 6.0 for requirements regarding the calibration of the sampling system flow rate and equipment for the determination of total flow.

8.2 Refer to the determinative method for procedures regarding calibration of the HPLC analysis system.

8.3 Barometer - Adjust the barometer initially and before each test series to agree within ±2.5 mm Hg (±0.1 in Hg) of the mercury barometer or the corrected barometric pressure value reported by a nearby National Weather Service Station (same altitude above sea level). Note that adjustment for elevation differences between the weather station and the sampling point is applied at a rate of minus 2.5 mm Hg (0.1 in Hg) per 30 m (100 ft) elevation increase.

8.4 Thermometers

8.4.1 If a mercury-in-glass reference thermometer is to be used, it must conform to ATSM E-1 63C or 63F specifications.

8.4.2 If a thermocouple is to be used, it must be calibrated in the laboratory according to the manufacturer's specifications. The calibration should be done both with and without the use of any extension leads.

9.0 CALCULATIONS

9.1 Calculation of the total volume of air sampled at standard conditions.

9.1.1 If a dry gas meter or equivalent total flow indicator is not used, the average sample flow rate, FR_{ave} in mL/minute, may be calculated using the following equation:

$$FR_{ave} = \frac{FR_1 + FR_2 + ... + FR_N}{N}$$

where:

$FR_1, FR_2, ..., FR_N$ = Flow rates determined at the beginning, end, and intermediate points during sampling

N = Number of flow rates averaged

9.1.2 The total volume of air sampled at the measured temperature and pressure, V_{Tot} in liters (L), may be calculated using the following equation:

$$V_{Tot} = \frac{(Time_2 - Time_1)(FR_{ave})}{1{,}000}$$

where:

$Time_2$ = Stop time (min)
$Time_1$ = Start time (min)
$(Time_2 - Time_1)$ = Total sampling time (min)
FR_{ave} = Average flow rate (mL/min)

9.1.3 The total volume of air sampled converted to standard conditions, V_{TotStd} in liter (L) at 25°C and 101.3 kPa, may be calculated using the following equation:

$$V_{TotStd} = V_{Tot} \times \frac{P_{ave}}{101.3\ kPa} \times \frac{298°C}{(273°C + T_{ave})}$$

where:

V_{Tot} = Total sample volume (L) at measured temperature and pressure
P_{ave} = Average indoor pressure (kPa)
T_{ave} = Average indoor temperature (°C)

10.0 DETERMINATION OF VOLUME TO BE SAMPLED

10.1 Refer to Table 1 for information regarding method "sensitivity" at various sampling volumes.

11.0 QUALITY CONTROL

11.1 Refer to Chapter One for quality control procedures.

11.2 Method Blanks - A method blank must be prepared for each set of analytical operations, to evaluate contamination and artifacts that can be derived from glassware, reagents, and sample handling in the laboratory.

11.3 Field Blanks - Field blanks must be submitted with the samples at each sampling site or 10% of the field samples, whichever is larger, should be shipped and analyzed with each group of samples. The field blank is treated identically to the samples except that no air is drawn through the cartridge. It is desirable to analyze blank cartridges retained in the laboratory (method blanks) as well, to distinguish between possible field and laboratory contamination.

11.4 Blank and Matrix Spikes - A procedure for spiking air sampling cartridges is not yet established for this sampling technique. Refer to Appendix A for information regarding possible techniques for accomplishing sample spiking. Proper QC procedures require that a blank spike and matrix spike be processed for each batch of 10 samples or less. As the MDL becomes better established for this method, the representative spike concentration should be set at 10 times the MDL, for that matrix, to account for interferences.

12.0 METHOD PERFORMANCE

12.1 The method detection limit (MDL) is defined as the minimum concentration of the test compound that can be measured and reported with 99 percent confidence as being greater than zero. The MDL actually achieved in a given analysis will vary, as it is dependent on instrument sensitivity and matrix effects. The MDLs for the target analytes in the method have not yet been established.

12.2 Table 1 illustrates the sensitivity for the target analytes of interest found in ambient air that have been identified using two Zorbax ODS columns in series.

[a] The ppb values are measured at 1 atm and 25°C. The sample cartridge is eluted with 5 mL acetonitrile and 25 µL is injected into the HPLC. The maximum sampling flow through a DNPH-coated Sep-PAK is about 1.5 L/minute.

[b] A sample volume of 1000 L was also performed. The results show a sensitivity of 0.01 ppb for all the target analytes.

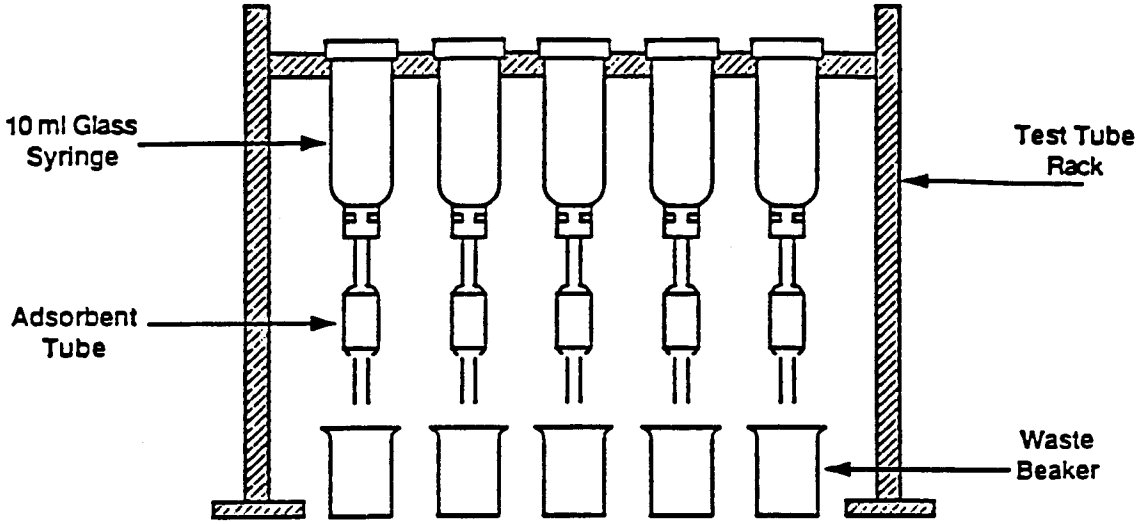
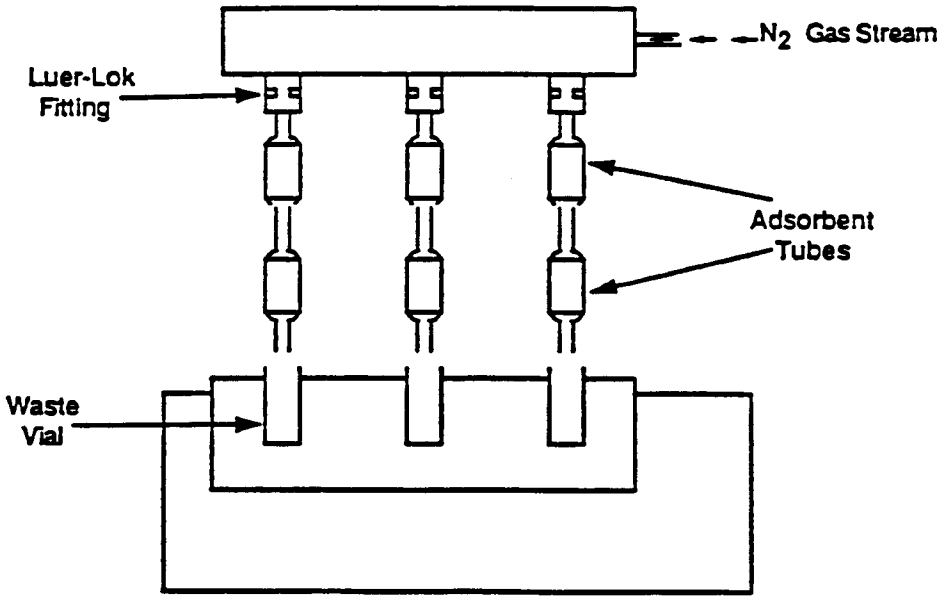
FIGURE 2

SYRINGE RACKS FOR COATING AND DRYING SAMPLE CARTRIDGES



(a) RACK FOR COATING CARTRIDGES



(b) RACK FOR DRYING DNPH-COATED CARTRIDGES

This method does not contain a procedure for spiking cartridges for blank spikes and matrix spikes to determine percent recovery. Two suggested techniques for spiking cartridges are as follows:

1) A spike may be performed by introducing an aliquot of a solution containing the target analytes by pipet or syringe directly onto a cartridge in the field or in the laboratory. Standard spike and recovery procedures are followed and the field spike sample is returned to the laboratory for analysis. An aliquot of the field spike standard is retained in the laboratory for derivatization and comparative analysis.

2) Another technique would include spiking the sampling cartridge using a TGM 555 analyzer which produces gaseous formaldehyde standards. However, it should be noted that the procedures required to produce accurate, dynamic, low-level standard mixtures of organics in air are non-routine. The techniques developed for use in evaluating other air sampling procedures employ a 3-stage dynamic gas dilution system coupled with a constant-rate vapor generation assembly containing a trioxane permeation tube (VICI Medtronics Dynacal permeation device or equivalent) that is maintained at 55°C. Trioxane vapor is converted stoichiometrically to formaldehyde vapor using a special high-temperature (160°C) catalytic converter assembly. This method of sample introduction has been used when testing continuous sampling apparatus.

METHOD 1010
PENSKY-MARTENS CLOSED-CUP METHOD FOR DETERMINING IGNITABILITY

1.0 SCOPE AND APPLICATION

1.1 Method 1010 uses the Pensky-Martens closed-cup tester to determine the flash point of liquids including those that tend to form a surface film under test conditions. Liquids containing non-filterable, suspended solids shall also be tested using this method.

2.0 SUMMARY OF METHOD

2.1 The sample is heated at a slow, constant rate with continual stirring. A small flame is directed into the cup at regular intervals with simultaneous interruption of stirring. The flash point is the lowest temperature at which application of the test flame ignites the vapor above the sample.

For further information on how to conduct a test by this method, see Reference 1 below.

3.0 METHOD PERFORMANCE

3.1 The Pensky-Martens and Setaflash Closed Testers were evaluated using five industrial waste mixtures and p-xylene. The results of this study are shown below in °F along with other data.

Sample	Pensky-Martens	Setaflash
1[2]	143.7 ± 1.5	139.3 ± 2.1
2[2]	144.7 ± 4.5	129.7 ± 0.6
3[2]	93.7 ± 1.5	97.7 ± 1.2
4[2]	198.0 ± 4.0	185.3 ± 0.6
5[2]	119.3 ± 3.1	122.7 ± 2.5
p-xylene[2]	81.3 ± 1.1	79.3 ± 0.6
p-xylene[3]	77.7 ± 0.5[a]	--
Tanker oil	125, 135	--
Tanker oil	180, 180	--
Tanker oil	110, 110	--
DIBK/xylene	102 ± 4[b]	107

[b]75/25 v/v analyzed by four laboratories.

METHOD 1020A

SETAFLASH CLOSED-CUP METHOD FOR DETERMINING IGNITABILITY

1.0 SCOPE AND APPLICATION

1.1 Method 1020 makes use of the Setaflash Closed Tester to determine the flash point of liquids that have flash points between 0° and 110°C (32° and 230°F) and viscosities lower than 150 stokes at 25°C (77°F).

1.2 The procedure may be used to determine whether a material will or will not flash at a specified temperature or to determine the finite temperature at which a material will flash.

1.3 Liquids that tend to form surface films under test conditions or those that contain non-filterable suspended solids shall be tested for ignitability using Method 1010 (Pensky-Martens Closed-Cup).

2.0 SUMMARY OF METHOD

2.1 By means of a syringe, 2-mL of sample is introduced through a leak-proof entry port into the tightly closed Setaflash Tester or directly into the cup which has been brought to within 3°C (5°F) below the expected flash point.

2.2 As a flash/no-flash test, the expected flash-point temperature may be a specification (e.g., 60°C). For specification testing, the temperature of the apparatus is raised to the precise temperature of the specification flash point by slight adjustment of the temperature dial. After 1 minute, a test flame is applied inside the cup and note is taken as to whether the test sample flashes or not. If a repeat test is necessary, a fresh sample should be used.

2.3 For a finite flash management, the temperature is sequentially increased through the anticipated range, the test flame being applied at 5°C (9°F) intervals until a flash is observed. A repeat determination is then made using a fresh sample, starting the test at the temperature of the last interval before the flash point of the material and making tests at increasing 0.5°C (1°F) intervals.

For further information on how to conduct a test with this method, see Reference 1 below.

3.0 METHOD PERFORMANCE

See Method 1010.

METHOD 1030

IGNITABILITY OF SOLIDS

1.0 SCOPE AND APPLICATION

1.1 This method is suitable for the determination of the ignitability of solids and is appropriate for pastes, granular materials, solids that can be cut into strips, and powdery substances. This method may be used to meet certain regulatory applications; with respect to the characteristic of ignitability in CFR § 261.21, this method may be used, but is not required, to determine whether a solid waste "when ignited, burns so vigorously and persistently that it creates a hazard." If it is impractical to perform the test because of the physical form of the sample, generator knowledge should be used to determine the ignitability hazard posed by the material.

2.0 SUMMARY OF METHOD

2.1 In a preliminary test, the test material is formed into an unbroken strip or powder train 250 mm in length. An ignition source is applied to one end of the test material to determine whether combustion will propagate along 200 mm of the strip within a specified time period. Materials that propagate burning along a 200 mm strip within the specified time period are then subjected to a burning rate test. Materials that do not ignite or propagate combustion as described above do not require further testing. In the burning rate test, the burning time is measured over a distance of 100 mm and the rate of burning is determined. The test method described here is based on the test procedure adopted by the Department of Transportation from the United Nations regulations for the international transportation of dangerous goods and is contained in Appendix E to Part 173 of 49 CFR.

3.0 INTERFERENCES

3.1 In laboratory tests the burning rate of duplicate runs is usually repeatable to within 10%. However, large differences in burning rates may occur if experimental conditions are not held constant. Variation in airflow rates, particle size, and moisture content of the test material will affect test results. Therefore, at least triplicate determinations of the burning rate should be conducted.

3.2 Particle size of test material can affect not only the burning rate, but also the ignition of the material. Therefore, the particle size of the test material should be the same for each test run. The particle size of the test material should be reported in a simple descriptive format (e.g., fine powder, sand, coarse granular).

3.3 Temperature of some test material such as sulfur powder affects the burning rate. For reproducible results, all tests should be performed at approximately the same initial temperature (ambient room or laboratory temperature).

3.4 All tests must be carried out inside a fume hood with the test apparatus situated perpendicular (90^{o}) to the direction of airflow. Airflow parallel (0^{o}) to the test apparatus results in non-reproducible burning rates.

3.5 The rate of airflow through the fume hood affects the burning rate. Too high an airflow distorts the flame and retards its horizontal propagation. The optimum airflow appears to be in the range of 0.7-1 meter per second.

3.6 Materials that are moisture sensitive (i.e., readily absorb moisture from air) should be tested as quickly as possible after removal from the sample container. All materials should be tested as received by the laboratory.

4.0 APPARATUS AND MATERIALS

4.1 Low-heat conducting, non-combustible, impervious ceramic tile or equivalent material, of approximate dimension of 25 cm x 25 cm x 2.5 cm (the tile must be at least 25 cm in length to support a 250 mm test sample).

4.2 High temperature marker or equivalent marking device for marking ceramic plates.

4.3 Powder Train Mold (see Figure 1) for molding powdered and granular materials for the burn rate test. The material of construction can be aluminum, brass, stainless steel, or plastic. The mold is 250 mm in length and has a triangular cross-section, with a width of 20 mm, and a depth of 10 mm as measured from the bottom of the triangular opening to where the sides meet. On both sides of the mold, in the longitudinal direction, two sheets are mounted as lateral limitations which extend 2 mm beyond the upper edge of the triangular cross-section. This device can be fabricated by most machine shops. The complete burn rate apparatus is available from: Associated Design and Manufacturing Co.; 814 N. Henry Street; Alexandria, Virginia 22314.

4.4 A Bunsen (propane gas and air) burner with a minimum diameter of 5 mm capable of attaining a temperature of at least 1,000^{o}C.

4.5 Stop watch.

4.6 Thermocouple to measure the temperature of the gas flame.

4.7 Thermometer to measure initial temperature of material (i.e., room temperature).

4.8 Anemometer to measure airflow in the fume hood.

5.0 REAGENTS

5.1 No special reagents are required to conduct this test.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples are tested on as-received basis unless requested otherwise. No sample preservation is required, but sample containers should be completely filled and tightly sealed to preserve sample integrity.

6.2 Samples should be tested as soon as possible after removal from the sample container (i.e., samples should not be allowed to dry or absorb moisture for excessive periods or to

lose volatiles). Samples that are chilled or cooled upon receipt to the laboratory should be allowed to equilibrate to the ambient laboratory temperature in the sample container.

7.0 PROCEDURE

SAFETY: Prior to starting the preliminary test, all sample materials must be tested to determine if that material is explosive or extremely flammable. Use a very small portion of material (1 gram or less). If the sample displays explosivity or extreme flammability, do not conduct this test.

7.1 Preliminary Screening Test

7.1.1 The preliminary ignitability test is conducted on all waste materials. On a clean, impervious ceramic tile (Section 4.1), clearly mark a 250 mm long test path. Make another mark at exactly 200 mm from the start of the sample path.

7.1.2 Prepare the test material in its "as received" form by forming an unbroken strip or powder train of sample 250 mm long by 20 mm wide by 10 mm high on the ceramic tile. Use the mold to form the material as in 7.2.3 if appropriate.

7.1.3 Place the ceramic tile with the loaded sample in a fume hood about 20 cm (~8 inches) from the front of the hood and in an area of laminar airflow. Position the sample perpendicular to the airflow. (See Figure 2) The airflow across the perpendicular axis of the sample should sufficient to prevent fumes from escaping into the laboratory and should not be varied during the test. The air velocity should be approximately 0.7 meters/second. Measure the air velocity by an anemometer.

7.1.4 Light the Bunsen burner and adjust the height of the flame (6.5 to 7.5 cm) by adjusting the propane gas and air flows. Measure the temperature of the flame (tip of the flame) by a thermocouple. The temperature of the flame must be at least 1000°C.

7.1.5 Apply the tip of the flame to one end of the sample strip . The test period will depend on the sample matrix as follows:

7.1.6 If the waste is non-metallic, hold the flame tip on the sample strip until the sample ignites or for a maximum of 2 minutes. If combustion occurs, begin timing with a stop watch and note whether the combustion propagates up to the 200 mm mark within the 2 minute test period.

7.1.7 If the waste is a metal or metal-alloy powder, hold the flame tip on the sample strip until the sample ignites or for a maximum of 5 minutes. If combustion occurs, begin timing with a stop watch and note whether the combustion propagates up to the 200 mm mark within the 20 minute test period.

7.1.8 If the waste does not ignite and propagate combustion either by burning with open flame or by smoldering along 200 mm of sample strip within the 2 minute test period (or 20 minute test period for metal powders), the waste is not considered flammable and no further testing is required. If the waste propagates burning of 200 mm of the test strip within

the 2 minute test period (20 minute test period for metals), the material must be evaluated by the burning rate test (Section 7.2).

7.2 Burning Rate Test

7.2.1 The preparation of the test sample for the burning rate test will depend on the physical characteristics of the waste. Wastes that exist in a powdered or granular state are molded in a powder train mold shown in Figure 1. Pasty materials are formed into a rope 250 mm in length with a cross-section of 1 cm^2. All tests for the burn rate test are performed on clean, ambient temperature, ceramic plates.

7.2.2 On a clean, impervious ceramic tile (Section 4.1), clearly mark a 250 mm long test path. Make two additional timing marks at 80 mm and 180 mm from the start of the sample path. The distance between the two marks (100 mm) will be used to calculate the rate of burn in Section 7.2.9.

7.2.3 Tighten the side plates on the mold. For powdered or granular materials: Place the mold on the base plate. Pour the material to fill the triangular cross section of the mold loosely.

7.2.4 Drop the unit from a height of 2 cm onto a solid surface three times to settle the powder. Remove the side supports. Lift the mold off the base plate. Place a clean ceramic test plate with the appropriate timing marks (Section 7.2.2) face down on top of the mold. Invert the setup and remove the mold.

7.2.5 Pasty wastes are prepared by spreading the waste on a marked ceramic tile (Section 7.2.2) in the form of a rope 250 mm in length with a cross-section of 1 cm^2.

7.2.6 Place the ceramic tile with the loaded sample prepared in Sections 7.2.3 or 7.2.5 in a fume hood about 20 cm (~8 inches) from the front of the hood and in an area of laminar airflow. Position the sample perpendicular to the airflow. (See Figure 2) The airflow across the perpendicular axis of the sample should sufficient to prevent fumes from escaping into the laboratory and should not be varied during the test. The air velocity should be approximately 0.7 meters/second. Measure the air velocity with an anemometer.

7.2.7 Light the Bunsen burner and adjust the height of the flame (6.5 to 7.5 cm) by adjusting the propane gas and air flows. Measure the temperature of the flame (tip of the flame) by a thermocouple. The temperature of the flame must be at least 1000°C.

7.2.8 Apply the tip of the flame to one end of the sample strip to ignite the test strip as described in Section 7.1.6 and 7.1.7.

7.2.9 When the test strip or powder train has burned up to the 80 mm time marker, begin timing the rate of combustion with a stop watch. Stop the timer when the burned strip reaches the 180 mm time marker. Record the amount of time (in seconds) required to burn the 100 mm test strip. Calculate the rate of burning by dividing the length of the burn test strip (100 mm) by the total time (seconds). Results of the burn rate test should be reported in mm/sec. Wastes that have a rate of burning of more than 2.2 mm/sec (or burn time of less than 45 seconds for 100 mm) are considered to have a positive result for ignitability

according to DOT regulations. For metals, this time is 10 minutes or less for 100 mm (or a burn rate of more than 0.17 mm/sec).

8.0 QUALITY CONTROL

8.1 All tests must be performed on a clean ceramic plate at room temperature. All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

8.2 All replicate runs must be at the same initial temperature (ambient laboratory temperature).

8.3 All replicate tests must be run at approximately the same airflow through the fume hood.

8.4 Only materials of the same particle size distribution should be used for all replicate tests.

8.5 The burn rate test must be conducted in triplicate if the preliminary screening test is positive. Any burn rate for non-metallic samples that exceeds 2.2 mm/sec (or a burn time of less than 45 seconds for 100 mm) is considered to have a positive result. For metals, a burn rate of more than 0.17 mm/sec (or burn time of less than 10 minutes for 100 mm) is considered to have a positive result.

9.0 METHOD PERFORMANCE

9.1 An independent laboratory validation was conducted on the robustness of the burn rate test procedure. The materials selected for this evaluation included:

1. A 50/50 mixture of metallic silicon and lead dioxide ($Pb0_2$)
2. Excelsior
3. Dextrin (yellow powder)
4. Sulfur (fine yellow powder)
5. Aluminum metal (coarse)
6. Magnesium metal (coarse)
7. Polyethylene high density (granular)
8. Polyethylene low density (fluffy white powder)
9. Scott fertilizer (32-3-10:N-P-K)
10. JP-4 contaminated soil (approximately 5000 ppm)

Of these materials, the 50/50 mixture of metallic silicon and lead dioxide ($Pb0_2$), elemental sulfur, and excelsior were considered to give a positive ignitability result under the conditions of the test. The remaining materials gave negative (nonflammable) results under the conditions of the test. Several test variables including ignition source, ambient temperature, and apparatus orientation, were studied using these materials. Partial results of this study are summarized in Table 1.

9.2 In another evaluation of the DOT burn rate test, potentially ignitable finishing wastes from the furniture industry were collected and tested for burning rates. Each waste was tested in triplicate to establish a mean value for the burning rate. The results for the flammable wastes are summarized in Table 2.

9.3 In order to evaluate the ruggedness of the DOT burn rate test, select ignitable finishing wastes were split and tested by a state laboratory and an independent contract laboratory. The results of this comparison are summarized in Table 3.

METHOD 1110

CORROSIVITY TOWARD STEEL

1.0 SCOPE AND APPLICATION

1.1 Method 1110 is used to measure the corrosivity toward steel of both aqueous and nonaqueous liquid wastes.

2.0 SUMMARY OF METHOD

2.1 This test exposes coupons of SAE Type 1020 steel to the liquid waste to be evaluated and, by measuring the degree to which the coupon has been dissolved, determines the corrosivity of the waste.

3.0 INTERFERENCES

3.1 In laboratory tests, such as this one, corrosion of duplicate coupons is usually reproducible to within 10%. However, large differences in corrosion rates may occasionally occur under conditions where the metal surfaces become passivated. Therefore, at least duplicate determinations of corrosion rate should be made.

4.0 APPARATUS AND MATERIALS

4.1 An apparatus should be used, consisting of a kettle or flask of suitable size (usually 500 to 5,000 mL), a reflux condenser, a thermowell and temperature regulating device, a heating device (mantle, hot plate, or bath), and a specimen support system. A typical resin flask set up for this type of test is shown in Figure 1.

4.2 The supporting device and container shall be constructed of materials that are not affected by, or cause contamination of, the waste under test.

4.3 The method of supporting the coupons will vary with the apparatus used for conducting the test, but it should be designed to insulate the coupons from each other physically and electrically and to insulate the coupons from any metallic container or other device used in the test. Some common support materials include glass, fluorocarbon, or coated metal.

4.4 The shape and form of the coupon support should ensure free contact with the waste.

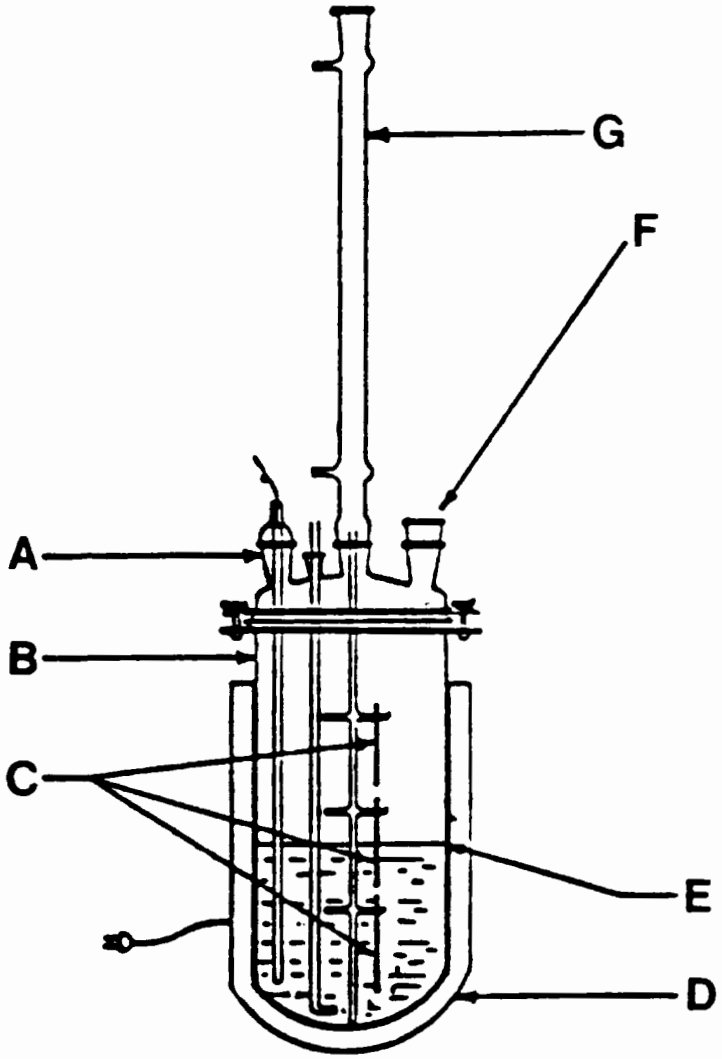

Figure 1. Typical resin flask that can be used as a versatile and convenient apparatus to conduct simple immersion tests. Configuration of the flask top is such that more sophisticated apparatus can be added as required by the specific test being conducted. A = thermowell, B = resin flask, C = specimens hung on supporting device, D = heating mantle, E = liquid interface, F = opening in flask for additional apparatus that may be required, and G = reflux condenser.

4.5 A circular specimen of SAE 1020 steel of about 3.75 cm (1.5 in.) diameter is a convenient shape for a coupon. With a thickness of approximately 0.32 cm (0.125 in.) and a 0.80-cm (0.4-in.)-diameter hole for mounting, these specimens will readily pass through a 45/50 ground-glass joint of a distillation kettle. The total surface area of a circular specimen is given by the following equation:

$$A = 3.14/2(D^2-d^2) + (t)(3.14)(D) + (t)(3.14)(d)$$

where:

t = thickness.
D = diameter of the specimen.
d = diameter of the mounting hole.

If the hole is completely covered by the mounting support, the last term in the equation, (t)(3.14)(d), is omitted.

4.5.1 All coupons should be measured carefully to permit accurate calculation of the exposed areas. An area calculation accurate to ±1% is usually adequate.

4.5.2 More uniform results may be expected if a substantial layer of metal is removed from the coupons prior to testing the corrosivity of the waste. This can be accomplished by chemical treatment (pickling), by electrolytic removal, or by grinding with a coarse abrasive. At least 0.254 mm (0.0001 in.) or 2-3 mg/cm^2 should be removed. Final surface treatment should include finishing with #120 abrasive paper or cloth. Final cleaning consists of scrubbing with bleach-free scouring powder, followed by rinsing in distilled water and then in acetone or methanol, and finally by air-drying. After final cleaning, the coupon should be stored in a desiccator until used.

4.5.3 The minimum ratio of volume of waste to area of the metal coupon to be used in this test is 40 mL/cm^2.

5.0 REAGENTS

5.1 Sodium hydroxide (NaOH), (20%): Dissolves 200 g NaOH in 800 mL Type II water and mix well.

5.2 Zinc dust.

5.3 Hydrochloric acid (HCl): Concentrated.

5.4 Stannous chloride ($SnCl_2$).

5.5 Antimony chloride ($SbCl_3$).

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples should be collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

7.0 PROCEDURE

7.1 Assemble the test apparatus as described in Paragraph 4.0, above.

7.2 Fill the container with the appropriate amount of waste.

7.3 Begin agitation at a rate sufficient to ensure that the liquid is kept well mixed and homogeneous.

7.4 Using the heating device, bring the temperature of the waste to 55°C (130°F).

7.5 An accurate rate of corrosion is not required; only a determination as to whether the rate of corrosion is less than or greater than 6.35 mm per year is required. A 24-hr test period should be ample to determine whether or not the rate of corrosion is >6.35 mm per year.

7.6 In order to determine accurately the amount of material lost to corrosion, the coupons have to be cleaned after immersion and prior to weighing. The cleaning procedure should remove all products of corrosion while removing a minimum of sound metal. Cleaning methods can be divided into three general categories: mechanical, chemical, and electrolytic.

7.6.1 Mechanical cleaning includes scrubbing, scraping, brushing, and ultrasonic procedures. Scrubbing with a bristle brush and mild abrasive is the most popular of these methods. The others are used in cases of heavy corrosion as a first step in removing heavily encrusted corrosion products prior to scrubbing. Care should be taken to avoid removing sound metal.

7.6.2 Chemical cleaning implies the removal of material from the surface of the coupon by dissolution in an appropriate solvent. Solvents such as acetone, dichloromethane, and alcohol are used to remove oil, grease, or resinous materials and are used prior to immersion to remove the products of corrosion. Solutions suitable for removing corrosion from the steel coupon are:

Solution	Soaking Time	Temperature
20% NaOH + 200 g/L zinc dust	5 min	Boiling
or		
Conc. HCl + 50 g/L $SnCl_2$ + 20 g/L $SbCl_3$	Until clean	Cold

7.6.3 Electrolytic cleaning should be preceded by scrubbing to remove loosely adhering corrosion products. One method of electrolytic cleaning that can be employed uses:

Solution:	50 g/L H_2SO_4
Anode:	Carbon or lead
Cathode:	Steel coupon
Cathode current density:	20 amp/cm^2 (129 amp/$in.^2$)
Inhibitor:	2 cc organic inhibitor/liter
Temperature:	74°C (165°F)
Exposure Period:	3 min.

NOTE: Precautions must be taken to ensure good electrical contact with the coupon to avoid contamination of the cleaning solution with easily reducible metal ions and to ensure that inhibitor decomposition has not occurred. Instead of a proprietary inhibitor, 0.5 g/L of either diorthotolyl thiourea or quinolin ethiodide can be used.

7.7 Whatever treatment is employed to clean the coupons, its effect in removing sound metal should be determined by using a blank (i.e., a coupon that has not been exposed to the waste). The blank should be cleaned along with the test coupon and its waste loss subtracted from that calculated for the test coupons.

7.8 After corroded specimens have been cleaned and dried, they are reweighed. The weight loss is employed as the principal measure of corrosion. Use of weight loss as a measure of corrosion requires making the assumption that all weight loss has been due to generalized corrosion and not localized pitting. In order to determine the corrosion rate for the purpose of this regulation, the following formula is used:

$$\text{Corrosion Rate (mmpy)} = \frac{\text{weight loss x } 11.145}{\text{area x time}}$$

where: weight loss is in milligrams,
area in square centimeters,
time in hours, and
corrosion rate in millimeters per year (mmpy).

8.0 QUALITY CONTROL

8.1 All quality control data should be filed and available for auditing.

8.2 Duplicate samples should be analyzed on a routine basis.

9.0 METHOD PERFORMANCE

9.1 No data provided.

METHOD 1120

DERMAL CORROSION

1.0 SCOPE AND APPLICATION

1.1 The dermal corrosion assay system is an *in vitro* test method which determines the corrosive potential of a substance toward human skin. The method is simple, rapid, accurate, and may be applied to both solids, liquids and emulsions. The liquids may be aqueous or non-aqueous. Solids can be water-soluble or non-soluble. The samples may be pure chemicals, dilutions, formulations, or waste. No prior treatment of the sample is required. This method may be used to meet certain regulatory applications, e.g., DOT corrosivity measurement for Packing Groups, but is not required for determining if a waste passes or fails the characteristic of corrosivity per the RCRA definition.

1.2 This method is applicable to a limited number of materials, specifically: Acids, inorganic and organic; acid derivatives (anhydride, halo acids, salts, etc.), inorganic and organic; acyl halides; alkylamines and polyalkylamines; bases, inorganic and organic; chlorosilanes; and metal halides and oxyhalides.

2.0 SUMMARY OF METHOD

2.1 The assay system is an *in vitro* test method which is composed of two components, a synthetic macromolecular biobarrier and a Chemical Detection System (CDS). Test samples are applied on top of the macromolecular biobarrier. Corrosive samples are able to disrupt the macromolecular structure of the biobarrier. A color change in the CDS, located beneath the biobarrier, is detected visually and indicates that the test sample has altered the biobarrier sufficiently to allow its passage through the full thickness of the biobarrier. The time it takes a sample to disrupt the biobarrier is inversely proportional to the degree of corrosivity of the sample - the longer it takes to observe a color change, the less corrosive the substance is. Noncorrosive samples do not disrupt the biobarrier, or disrupt the biobarrier after a predetermined time period (see Section 2.4).

Corrosive samples may be placed into three different classes of corrosivity, established by the time required for the sample to break through the biobarrier. These classes are called Packing Groups by the U.S. Department of Transportation (DOT). Packing Groups are assigned according to the degree of danger presented by the corrosive material; Packing Group I indicates great danger; Packing Group II, medium danger; Packing Group III, minor danger. For consistency, these same definitions are used for this test method and are referred to as Group I, Group II, and Group III.

2.2 Prior to performing the assay, samples are pre-qualified to establish their compatibility with the assay system. The sample is placed in a small amount of CDS fluid. If any detectable change occurs in the CDS, the sample is qualified and can be analyzed by the test. If a sample is non-qualified, it is incompatible with the CDS and must be tested by another method.

2.3 Test samples are classified into categories by the screening test which is supplied with the assay kit. The category that a sample is assigned to will determine how the Groups will be assigned. Test samples are classified by pH changes produced in two well-defined buffers - one designed to buffer acids and another that buffers bases. These buffers are supplied as part of the screening test. Four different categories are defined as follows:

2.3.1 Category A_1 substances produce a large change in pH when they are added to the acid buffer. This change in pH is indicated by a strong color change of the acid buffer solution.

2.3.2 Category B_1 substances produce a large change in pH when they are added to the base buffer. This change in pH is indicated by a strong color change of the base buffer solution.

2.3.3 Category A_2 substances produce little or no pH changes when added to the acid buffer, and therefore, little or no color change in the buffer solution is observed.

2.3.4 Category B_2 substances produce little or no pH changes when added to the base buffer, and therefore, little or no color change in the buffer solution is observed.

2.4 Groups are assigned in the assay system by taking into account the category that is assigned to a sample by the screening test, and the time it takes to detect a color change in the CDS in the assay. Category A_1 and B_1 samples are assigned to Group I if a color change is observed between zero and three minutes, to Group II if a color change is observed after three minutes and up to one hour, and to Group III if a color change is observed after one hour and up to four hours. If no color change occurs in four hours, the chemical is classified as Noncorrosive.

Category A_2 and B_2 samples are assigned to Group I if a color change is observed between zero and three minutes, to Group II if a color change is observed after three minutes and up to 30 minutes, and to Group III if a color change is observed after 30 minutes and up to 60 minutes. If no color change occurs in 60 minutes, the chemical is classified as Noncorrosive.

3.0 INTERFERENCES

3.1 The test is not subject to interference from color, turbidity, colloidal matter or high salinity.

3.2 The Pre-qualification Test, the Screening Test and the Assay must be performed at room temperature. The samples must also be at room temperature (17- 25°C).

4.0 APPARATUS AND MATERIALS

4.1 Corrositex Assay Kit (InVitro International, 16632 Millikan Avenue, Irvine, CA 92714). The following three items are supplied in the Corrositex Assay Kit:

4.1.1 Four racks holding seven vials with black caps.

4.1.2 One tray of 24 membrane discs.

4.1.3 Four data sheets (color charts).

4.2 Combination hot plate/stir plate or equivalent - able to heat to 75°C. Stirring speed should be adjustable.

4.3 Digital thermometer - able to read to 75°C.

4.4 Timers (6) - able to measure hours, minutes and seconds.

4.5 Repeat pipettor - this pipet is different than the pipet specified in Section 4.12. Delivers 200 µL repeatedly, without refilling between individual deliveries.

4.6 2.5 mL combitip for repeat pipettor.

4.7 Lab Industries or equivalent sample pipettor - a positive displacement pipettor useful when pipetting viscous samples.

4.8 Pipet tips for Lab Industries, or equivalent, pipettor.

4.9 Test tubes

4.10 Balance - capable of weighing 100 mg accurately.

4.11 Spatula - capable of transferring 0.1 - 0.5 g.

4.12 Pipets - microliter, with disposable tips. Should be able to measure 100 µL accurately.

4.13 Tweezers.

4.14 Permanent marker pens.

4.15 Plastic wrap.

5.0 REAGENTS

5.1 All reagents listed below are provided in the Corrositex Assay Kit except for the positive and negative controls mentioned in Section 5.7. The Corrositex Assay Kit is available from InVitro International, 16632 Millikan Avenue, Irvine, CA 92714.

5.2 Chemical Detection System (CDS).

5.3 Screening test buffer solutions.

5.4 Confirmation Test Solution.

5.5 One gram of the biobarrier matrix and a microstir bar.

5.6 10 mL of biobarrier diluent.

5.7 Positive and negative controls, if desired, for GLP purposes.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Appropriate precautions should be taken for handling potentially corrosive substances such as wearing gloves and having proper eye protection.

6.2 Samples should be analyzed as soon as possible after collection.

7.0 PROCEDURE

7.1 Follow the established laboratory procedures for working with hazardous test samples. Wear lab coat, gloves and safety glasses when working with any potentially corrosive material.

7.2 Pre-Qualification Test

7.2.1 Add 100 mg or 150 µL of sample to 1.0 mL of CDS in duplicate test tubes.

7.2.1.1 Sample qualifies if there is a color reaction within 5 minutes: proceed with assay.

7.2.1.2 If no reaction is observed, the sample is non-qualified. Seek other methods to determine corrosivity.

7.3 Screening Test

7.3.1 Liquid samples

7.3.1.1 Add 150 µL of sample to Test Tubes A and B. Cap the test tubes and shake vigorously for 10 seconds. Read the color change of the mixture within one minute. If the sample is immiscible in the solution, wait one minute and then read the color change at the interface.

7.3.1.2 Assign the category. If an intense color change (similar to the Category 1 color chart) is observed in Tube A or Tube B, assign the sample to Category 1. If a less intense color change (similar to the Category 2 color chart) is observed in either Tube A or Tube B, assign the sample to Category 2 . If no color change is observed in either Tube A or Tube B, proceed to the next step.

7.3.1.3 Confirm test. Add two drops of the Confirm reagent to Tube B. Cap the test tube and shake vigorously for 5 seconds. The color of the solution will match one of the colors shown in the accompanying color chart, confirming that the sample is Category 2 material.

7.3.2 Solid samples

7.3.2.1 Add 100 mg of sample to Test Tubes A and B. Cap the test tubes and shake vigorously for one minute. Wait another minute and read the color change of the mixture. If the sample is insoluble in the solution, allow the mixture to settle and read the color change at the interface of the solution and the solid.

7.3.2.2 Assign the category. If an intense color change (similar to the Category 1 color chart) is observed in either Tube A or Tube B, assign the sample to Category 1. If a less intense color change (similar to the Category 2 color chart) is observed in either Tube A or Tube B, assign the sample to Category 2. If no color change is observed in either Tube A or Tube B, proceed to the next step.

7.3.2.3 Confirm test. Add two drops of the Confirm reagent to Tube B. Cap the test tube and shake vigorously for 5 seconds. The color of the solution will match one of the colors shown in the accompanying color chart, confirming that the sample is Category 2 material.

7.4 Assay

7.4.1 Biobarrier preparation

7.4.1.1 Biobarrier matrix preparation - must be completed at least two hours prior to running assay.

7.4.1.2 Place scintillation vial containing biobarrier matrix powder on the hot plate pad. Begin spinning the stir bar before adding the diluent.

7.4.1.3 Add the entire contents of the biobarrier diluent vial slowly and constantly to the vial of biobarrier matrix powder. Make sure that the stir bar is turning while adding the diluent. The stir bar should be turning rapidly, but not so fast that the solution foams.

7.4.1.4 Turn the heat on low; monitor the temperature of the solution as it is warming. Gradually increase the heat as necessary to warm the solution to 68°C (±1°C) to solubilize the matrix. This may take approximately 20 minutes. **DO NOT** allow the temperature to exceed 70°C.

7.4.1.5 While the solution is warming, remove the tray of 24 membrane discs from the refrigerator. Remove the tray lid.

7.4.1.6 After the biobarrier matrix solution reaches 68°C and has been completely solubilized, turn off the heat and move the vial toward the edge of the heat pad to keep it warm while aliquotting into the membrane discs.

7.4.1.7 Dispense solubilized solution into membrane discs. Using the repeat pipettor, set to dispense 200 µL. Slowly fill the pipette tip with biobarrier solution, avoiding air bubbles. Dispense one aliquot back into the biobarrier vial to ensure proper subsequent volume delivery. Wipe the tip before dispensing each aliquot. Dispense 200 µL into each disc, ensuring that the entire membrane is covered and no air bubbles have formed. Any air bubbles in the gel will alter the results of the test, therefore the disc cannot be used.

7.4.1.8 Label the lid with the date, time, lot number, and initials of the technician preparing the biobarrier. Wrap the filled tray evenly with plastic wrap; do not bunch up the plastic wrap underneath the plate.

7.4.1.9 Store the tray at 2 - 8°C for at least two hours before beginning any testing. The biobarrier is stable for seven days if wrapped and stored at 2 - 8°C.

7.4.2 Running the assay.

7.4.2.1 On the data sheet, complete the lot number, date, time, name of technician, name of chemical, whether it is solid or liquid, and pH of a 10% solution diluted in water or appropriate solvent.

7.4.2.2 When ready to test, remove one tray of seven pre-filled black-capped scintillation vials from the kit box.

7.4.2.3 Remove the tray of 24 membrane discs from the refrigerator. Place on a tray of ice.

7.4.2.4 Place disc into first scintillation vial. Do not allow the discs to be in contact with the CDS for longer than two minutes before applying the test sample. Within two minutes, add 500 µL (using the Lab Industries pipettor, or equivalent) or 500 mg (using spatula or tweezers) of test sample to disc. Start timer the instant the sample is added.

Note: Do not cap the vials while test is in progress due to potential pressure build-up.

7.4.2.5 Watch the vial for three minutes, ensuring that the color reaction is not missed if it is a Group I sample. Changes in the CDS may include various color changes, flaking or precipitation.

7.4.2.6 Add three more discs and samples to vials, staggering each start time so that the most accurate reaction times are recorded.

7.4.2.7 Allow assay to run until color or physical reaction occurs. Category 1 samples should be checked for reactions at 3 minutes, 1 hour and 4 hours. Category 2 samples should be checked for reactions at 3, 30 and 60 minutes.

7.4.2.8 At the first indication of the presence of a chemical reaction in the CDS, there will be a color change produced beneath the bottom-center of each biobarrier disc. As soon as a reaction is observed, immediately record net time of each vial on the data sheet.

7.4.2.9 Run positive and negative controls in the other two vials, if desired, for GLP purposes.

7.4.3 Assignment of Groups.

7.4.3.1 Category 1 samples are assigned to Group I if a color change is observed between zero and three minutes, to Group II if a color change is observed after three minutes and up to one hour, and to Group III if a color change is observed after one hour and up to four hours. If no color change occurs in four hours, the chemical is classified as Noncorrosive.

7.4.3.2 Category 2 samples are assigned to Group I if a color change is observed between zero and three minutes, to Group II if a color change is observed after three minutes and up to 30 minutes, and to Group III if a color change is observed after 30 minutes and up to 60 minutes. If no color change occurs in 60 minutes, the chemical is classified as Noncorrosive.

8.0 QUALITY CONTROL

8.1 Samples should be analyzed in quadruplicate. The test may be analyzed in duplicate if a simple screening of corrosives and noncorrosives is all that is required. However, it is recommended that for greater accuracy, samples be analyzed in quadruplicate. It is suggested that positive and negative controls be analyzed to conform with GLP.

9.0 METHOD PERFORMANCE

9.1 Interlaboratory and intralaboratory studies were conducted with five different laboratories. Ten different chemicals were tested with six replicates. The data are presented in Table 1.

9.2 More than 200 data points have been collected at InVitro International for six reference samples. Statistical analysis of this data shows the standard deviation for ethylenediamine and ferric chloride is about 5% of their respective assay times, and about 10% for maleic anhydride, sodium hydroxide, and dicyclohexylamine. The standard deviation for sulfuric acid approaches 18% of its assay time, but when taken into account that the mean assay time is less than 1 minute, a standard deviation of 0.13 minutes is actually a reflection of the difficulty of measuring such brief time periods.

9.3 The Corrositex assay has been used by more than 300 laboratories to test approximately 4,000 test materials in its first phase of utilization in industry. Diverse chemicals and formulations which include liquids, solids, insolubles and immiscibles have been studied from many major industries including petrochemical, agrochemical, surfactant, textile, paper and pulp, electroplating and water treatment. Examples of dermal corrosion values compared to pH for selected compounds are shown in Table 2.

9.4 Data results from 1,050 samples that have been tested using the assay system were complied and compared with *in vivo* data. Ninety-two percent of the samples (965 samples) passed the Pre-qualification Test and were then analyzed in the screening test and the assay. Assay was found to be highly concordant with corrosive/noncorrosive *in vivo* results. Of 406 corrosive samples with *in vivo* data, 377 (93%) were correctly identified as corrosive by assay. Of 296 noncorrosive samples with *in vivo* data, 83% were identified as noncorrosives, demonstrating the ability of this *in vitro* method to correctly identify corrosives and noncorrosives. Assay was also shown to accurately predict Packing Groups. Six hundred out of 702 samples (85.5%) were placed in the same Packing Group as that indicated by *in vivo* testing. Only 38 test samples out of 702 samples that had *in vivo* data were found to underestimate (5.4%). Of these 38 samples, 28 were distinct samples and the remainder were samples that had been tested in more than one laboratory. When taking this information into account, the percent of underestimation decreased to about 4%.

METHOD 1310A

EXTRACTION PROCEDURE (EP) TOXICITY TEST METHOD AND STRUCTURAL INTEGRITY TEST

1.0 SCOPE AND APPLICATION

1.1 This method is an interim method to determine whether a waste exhibits the characteristic of Extraction Procedure Toxicity.

1.2 The procedure may also be used to simulate the leaching which a waste may undergo if disposed of in a sanitary landfill. Method 1310 is applicable to liquid, solid, and multiphase samples.

2.0 SUMMARY OF METHOD

2.1 If a representative sample of the waste contains > 0.5% solids, the solid phase of the sample is ground to pass a 9.5 mm sieve and extracted with deionized water which is maintained at a pH of 5 $\pm$ 0.2, with acetic acid. Wastes that contain < 0.5% filterable solids are, after filtering, considered to be the EP extract for this method. Monolithic wastes which can be formed into a cylinder 3.3 cm (dia) x 7.1 cm, or from which such a cylinder can be formed which is representative of the waste, may be evaluated using the Structural Integrity Procedure instead of being ground to pass a 9.5-mm sieve.

3.0 INTERFERENCES

3.1 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.0 APPARATUS AND MATERIALS

4.1 Extractor - For purposes of this test, an acceptable extractor is one that will impart sufficient agitation to the mixture to (1) prevent stratification of the sample and extraction fluid and (2) ensure that all sample surfaces are continuously brought into contact with well-mixed extraction fluid. Examples of suitable extractors are shown in Figures 1-3 of this method and are available from: Associated Designs & Manufacturing Co., Alexandria, Virginia; Glas-Col Apparatus Co., Terre Haute, Indiana; Millipore, Bedford, Massachusetts; and Rexnard, Milwaukee, Wisconsin.

4.2 pH meter or pH controller - Accurate to 0.05 pH units with temperature compensation.

4.3 Filter holder - Capable of supporting a 0.45-µm filter membrane and of withstanding the pressure needed to accomplish separation. Suitable filter holders range from simple vacuum units to relatively complex systems that can exert up to 5.3 kg/cm^3 (75 psi) of pressure. The type of filter holder used depends upon the properties of the mixture to be filtered. Filter holders known to EPA and deemed suitable for use are listed in Table 1.

4.4 Filter membrane - Filter membrane suitable for conducting the required filtration shall be fabricated from a material that (1) is not physically changed by the waste material to be filtered and (2) does not absorb or leach the chemical species for which a waste's EP extract will be analyzed. Table 2 lists filter media known to the agency to be suitable for solid waste testing.

4.4.1 In cases of doubt about physical effects on the filter, contact the filter manufacturer to determine if the membrane or the prefilter is adversely affected by the particular waste. If no information is available, submerge the filter in the waste's liquid phase. A filter that undergoes visible physical change after 48 hours (i.e., curls, dissolves, shrinks, or swells) is unsuitable for use.

4.4.2 To test for absorption or leaching by the filter:

4.4.2.1 Prepare a standard solution of the chemical species of interest.

4.4.2.2 Analyze the standard for its concentration of the chemical species.

4.4.2.3 Filter the standard and reanalyze. If the concentration of the filtrate differs from that of the original standard, then the filter membrane leaches or absorbs one or more of the chemical species and is not usable in this test method.

4.5 Structural integrity tester - A device meeting the specifications shown in Figure 4 and having a 3.18-cm (1.25-in) diameter hammer weighing 0.33 kg (0.73 lb) with a free fall of 15.24 cm (6 in) shall be used. This device is available from Associated Design and Manufacturing Company, Alexandria, VA 22314, as Part No. 125, or it may be fabricated to meet these specifications.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Acetic acid (0.5N), CH_3COOH. This can be made by diluting concentrated glacial acetic acid (17.5N) by adding 57 mL glacial acetic acid to 1,000 mL of water and diluting to 2 liters. The glacial acetic acid must be of high purity and monitored for impurities.

5.4 Analytical standards should be prepared according to the applicable analytical methods.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must be collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 Preservatives must not be added to samples.

6.3 Samples can be refrigerated if it is determined that refrigeration will not affect the integrity of the sample.

7.0 PROCEDURE

7.1 If the waste does not contain any free liquid, go to Step 7.9. If the sample is liquid or multiphase, continue as follows. Weigh filter membrane and prefilter to $\pm$ 0.01 g. Handle membrane and prefilters with blunt curved-tip forceps or vacuum tweezers, or by applying suction with a pipet.

7.2 Assemble filter holder, membranes, and prefilters following the manufacturer's instructions. Place the 0.45-µm membrane on the support screen and add prefilters in ascending order of pore size. Do not prewet filter membrane.

7.3 Weigh out a representative subsample of the waste (100 g minimum).

7.4 Allow slurries to stand, to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration.

7.5 Wet the filter with a small portion of the liquid phase from the waste or from the extraction mixture. Transfer the remaining material to the filter holder and apply vacuum or gentle pressure (10-15 psi) until all liquid passes through the filter. Stop filtration when air or pressurizing gas moves through the membrane. If this point is not reached under vacuum or gentle pressure, slowly increase the pressure in 10-psi increments to 75 psi. Halt filtration when liquid flow stops. This liquid will constitute part or all of the extract (refer to Step 7.16). The liquid should be refrigerated until time of analysis.

NOTE: Oil samples or samples containing oil are treated in exactly the same way as any other sample. The liquid portion of the sample is filtered and treated as part of the EP extract. If the liquid portion of the sample will not pass through the filter (usually the case with heavy oils or greases), it should be carried through the EP extraction as a solid.

7.6 Remove the solid phase and filter media and, while not allowing them to dry, weigh to $\pm$ 0.01 g. The wet weight of the residue is determined by calculating the weight difference between the weight of the filters (Step 7.1) and the weight of the solid phase and the filter media.

7.7 The waste will be handled differently from this point on, depending on whether it contains more or less than 0.5% solids. If the sample appears to have < 0.5% solids, determine the percent solids exactly (see Note below) by the following procedure:

7.7.1 Dry the filter and residue at 80°C until two successive weighings yield the same value.

7.7.2 Calculate the percent solids, using the following equation:

$$\frac{\text{weight of filtered solid and filters} - \text{tared weight of filters}}{\text{initial weight of waste material}} \times 100 = \% \text{ solids}$$

NOTE: This procedure is used only to determine whether the solid must be extracted or whether it can be discarded unextracted. It is not used in calculating the amount of water or acid to use in the extraction step. Do not extract solid material that has been dried at 80°C. A new sample will have to be used for extraction if a percent solids determination is performed.

7.8 If the solid constitutes < 0.5% of the waste, discard the solid and proceed immediately to Step 7.17, treating the liquid phase as the extract.

7.9 The solid material obtained from Step 7.5 and all materials that do not contain free liquids shall be evaluated for particle size. If the solid material has a surface area per g of material $\geq$ 3.1 cm^2 or passes through a 9.5-mm (0.375-in.) standard sieve, the operator shall proceed to Step 7.11. If the surface area is smaller or the particle size larger than specified above, the solid material shall be prepared for extraction by crushing, cutting, or grinding the material so that it passes through a 9.5-mm (0.375-in.) sieve or, if the material is in a single piece, by subjecting the material to the "Structural Integrity Procedure" described in Step 7.10.

7.10 Structural Integrity Procedure (SIP)

7.10.1 Cut a 3.3-cm diameter by 7.1-cm long cylinder from the waste material. If the waste has been treated using a fixation process, the waste may be cast in the form of a cylinder and allowed to cure for 30 days prior to testing.

7.10.2 Place waste into sample holder and assemble the tester. Raise the hammer to its maximum height and drop. Repeat 14 additional times.

7.10.3 Remove solid material from tester and scrape off any particles adhering to sample holder. Weigh the waste to the nearest 0.01 g and transfer it to the extractor.

7.11 If the sample contains > 0.5% solids, use the wet weight of the solid phase (obtained in Step 7.6) to calculate the amount of liquid and acid to employ for extraction by using the following equation:

$$W = W_f - W_t$$

where :

W = Wet weight in g of solid to be charged to extractor.

W_f = Wet weight in g of filtered solids and filter media.

W_t = Weight in g of tared filters.

If the waste does not contain any free liquids, 100 g of the material will be subjected to the extraction procedure.

7.12 Place the appropriate amount of material (refer to Step 7.11) into the extractor and add 16 times its weight with water.

7.13 After the solid material and water are placed in the extractor, the operator shall begin agitation and measure the pH of the solution in the extractor. If the pH is > 5.0, the pH of the solution should be decreased to 5.0 $\pm$ 0.2 by slowly adding 0.5N acetic acid. If the pH is $\leq$ 5.0, no acetic acid should be added. The pH of the solution should be monitored, as described below, during the course of the extraction, and, if the pH rises above 5.2, 0.5N acetic acid should be added to bring the pH down to 5.0 $\pm$ 0.2. However, in no event shall the aggregate amount of acid added to the solution exceed 4 mL of acid per g of solid. The mixture should be agitated for 24 hours and maintained at 20-40°C (68-104°F) during this time. It is recommended that the operator monitor and adjust the pH during the course of the extraction with a device such as the Type 45-A pH Controller, manufactured by Chemtrix, Inc., Hillsboro, Oregon 97123, or its equivalent, in conjunction with a metering pump and reservoir of 0.5N acetic acid. If such a system is not available, the following manual procedure shall be employed.

NOTE: Do not add acetic acid too quickly. Lowering the pH to below the target concentration of 5.0 could affect the metal concentrations in the leachate.

7.13.1 A pH meter should be calibrated in accordance with the manufacturer's specifications.

7.13.2 The pH of the solution should be checked, and, if necessary, 0.5 N acetic acid should be manually added to the extractor until the pH reaches 5.0 $\pm$ 0.2. The pH of the solution should be adjusted at 15-, 30-, and 60-minute intervals, moving to the next longer interval if the pH does not have to be adjusted > 0.5 pH units.

7.13.3 The adjustment procedure should be continued for at least 6 hours.

7.13.4 If, at the end of the 24-hour extraction period, the pH of the solution is not below 5.2 and the maximum amount of acid (4 mL per g of solids) has not been added, the pH should be adjusted to 5.0 $\pm$ 0.2 and the extraction continued for an additional 4 hours, during which the pH should be adjusted at 1-hour intervals.

7.14 At the end of the extraction period, water should be added to the extractor in an amount determined by the following equation:

$$V = (20)(W) - 16(W) - A$$

where:

V = mL water to be added.

W = Weight in g of solid charged to extractor.

A = mL of 0.5N acetic acid added during extraction.

7.15 The material in the extractor should be separated into its component liquid and solid phases in the following manner:

7.15.1 Allow slurries to stand to permit the solid phase to settle (wastes that are slow to settle may be centrifuged prior to filtration) and set up the filter apparatus (refer to Steps 4.3 and 4.4).

7.15.2 Wet the filter with a small portion of the liquid phase from the waste or from the extraction mixture. Transfer the remaining material to the filter holder and apply vacuum or gentle pressure (10-15 psi) until all liquid passes through the filter. Stop filtration when air or pressurizing gas moves through the membrane. If this point is not reached under vacuum or gentle pressure, slowly increase the pressure in 10-psi increments to 75 psi. Halt filtration when liquid flow stops.

7.16 The liquids resulting from Steps 7.5 and 7.15 should be combined. This combined liquid (or waste itself, if it has < 0.5% solids, as noted in Step 7.8) is the extract.

7.17 The extract is then prepared and analyzed using the appropriate analytical methods described in Chapters Three and Four of this manual.

NOTE: If the EP extract includes two phases, concentration of contaminants is determined by using a simple weighted average. For example: An EP extract contains 50 mL of oil and 1,000 mL of an aqueous phase. Contaminant concentrations are determined for each phase. The final contamination concentration is taken to be:

$$\frac{\left(50 \times \text{contaminant conc. in oil}\right) + \left(1{,}000 \times \text{contaminant conc. of aqueous phase}\right)}{1050}$$

NOTE: In cases where a contaminant was not detected, use the MDL in the calculation. For example, if the MDL in the oily phase is 100 mg/L and 1 mg/L in the aqueous phase, the reporting limit would be 6 mg/L (rounded to the nearest mg). If the regulatory threshold is 5 mg/L, the waste may be EP toxic and results of the analysis are inconclusive.

8.0 QUALITY CONTROL

8.1 All quality control data should be maintained and available for easy reference or inspection.

8.2 Employ a minimum of one blank per sample batch to determine if contamination or any memory effects are occurring.

8.3 All quality control measures described in Chapter One and in the referenced analytical methods should be followed.

9.0 METHOD PERFORMANCE

9.1 The data tabulated in Table 3 were obtained from records of state and contractor laboratories and are intended to show the precision of the entire method (1310 plus analysis method).

METHOD 1311

TOXICITY CHARACTERISTIC LEACHING PROCEDURE

1.0 SCOPE AND APPLICATION

1.1 The TCLP is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

1.2 If a total analysis of the waste demonstrates that individual analytes are not present in the waste, or that they are present but at such low concentrations that the appropriate regulatory levels could not possibly be exceeded, the TCLP need not be run.

1.3 If an analysis of any one of the liquid fractions of the TCLP extract indicates that a regulated compound is present at such high concentrations that, even after accounting for dilution from the other fractions of the extract, the concentration would be above the regulatory level for that compound, then the waste is hazardous and it is not necessary to analyze the remaining fractions of the extract.

1.4 If an analysis of extract obtained using a bottle extractor shows that the concentration of any regulated volatile analyte exceeds the regulatory level for that compound, then the waste is hazardous and extraction using the ZHE is not necessary. However, extract from a bottle extractor cannot be used to demonstrate that the concentration of volatile compounds is below the regulatory level.

2.0 SUMMARY OF METHOD

2.1 For liquid wastes (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 μm glass fiber filter, is defined as the TCLP extract.

2.2 For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. A special extractor vessel is used when testing for volatile analytes (see Table 1 for a list of volatile compounds). Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 μm glass fiber filter.

2.3 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3.0 INTERFERENCES

3.1 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.0 APPARATUS AND MATERIALS

4.1 Agitation apparatus: The agitation apparatus must be capable of rotating the extraction vessel in an end-over-end fashion (see Figure 1) at 30 ± 2 rpm. Suitable devices known to EPA are identified in Table 2.

4.2 Extraction Vessels

4.2.1 Zero-Headspace Extraction Vessel (ZHE). This device is for use only when the waste is being tested for the mobility of volatile analytes (i.e., those listed in Table 1). The ZHE (depicted in Figure 2) allows for liquid/solid separation within the device, and effectively precludes headspace. This type of vessel allows for initial liquid/solid separation, extraction, and final extract filtration without opening the vessel (see Section 4.3.1). The vessels shall have an internal volume of 500-600 mL, and be equipped to accommodate a 90-110 mm filter. The devices contain VITON®[1] O-rings which should be replaced frequently. Suitable ZHE devices known to EPA are identified in Table 3.

For the ZHE to be acceptable for use, the piston within the ZHE should be able to be moved with approximately 15 psi or less. If it takes more pressure to move the piston, the O-rings in the device should be replaced. If this does not solve the problem, the ZHE is unacceptable for TCLP analyses and the manufacturer should be contacted.

The ZHE should be checked for leaks after every extraction. If the device contains a built-in pressure gauge, pressurize the device to 50 psi, allow it to stand unattended for 1 hour, and recheck the pressure. If the device does not have a built-in pressure gauge, pressurize the device to 50 psi, submerge it in water, and check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted.

Some ZHEs use gas pressure to actuate the ZHE piston, while others use mechanical pressure (see Table 3). Whereas the volatiles procedure (see Section 7.3) refers to pounds per square inch (psi), for the mechanically actuated piston, the pressure applied is measured in torque-inch-pounds. Refer to the manufacturer's instructions as to the proper conversion.

---

[1] VITON® is a trademark of Du Pont.

4.2.2 Bottle Extraction Vessel. When the waste is being evaluated using the nonvolatile extraction, a jar with sufficient capacity to hold the sample and the extraction fluid is needed. Headspace is allowed in this vessel.

The extraction bottles may be constructed from various materials, depending on the analytes to be analyzed and the nature of the waste (see Section 4.3.3). It is recommended that borosilicate glass bottles be used instead of other types of glass, especially when inorganics are of concern. Plastic bottles, other than polytetrafluoroethylene, shall not be used if organics are to be investigated. Bottles are available from a number of laboratory suppliers. When this type of extraction vessel is used, the filtration device discussed in Section 4.3.2 is used for initial liquid/solid separation and final extract filtration.

4.3 Filtration Devices: It is recommended that all filtrations be performed in a hood.

4.3.1 Zero-Headspace Extractor Vessel (ZHE): When the waste is evaluated for volatiles, the zero-headspace extraction vessel described in Section 4.2.1 is used for filtration. The device shall be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50 psi).

NOTE: When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE.

4.3.2 Filter Holder: When the waste is evaluated for other than volatile analytes, any filter holder capable of supporting a glass fiber filter and able to withstand the pressure needed to accomplish separation may be used. Suitable filter holders range from simple vacuum units to relatively complex systems capable of exerting pressures of up to 50 psi or more. The type of filter holder used depends on the properties of the material to be filtered (see Section 4.3.3). These devices shall have a minimum internal volume of 300 mL and be equipped to accommodate a minimum filter size of 47 mm (filter holders having an internal capacity of 1.5 L or greater, and equipped to accommodate a 142 mm diameter filter, are recommended). Vacuum filtration can only be used for wastes with low solids content (<10%) and for highly granular, liquid-containing wastes. All other types of wastes should be filtered using positive pressure filtration. Suitable filter holders known to EPA are shown in Table 4.

4.3.3 Materials of Construction: Extraction vessels and filtration devices shall be made of inert materials which will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) may be used only when evaluating the mobility of metals. Borosili-

cate glass bottles are recommended for use over other types of glass bottles, especially when inorganics are analytes of concern.

4.4 Filters: Filters shall be made of borosilicate glass fiber, shall contain no binder materials, and shall have an effective pore size of 0.6 to 0.8 µm, or equivalent. Filters known to EPA which meet these specifications are identified in Table 5. Pre-filters must not be used. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1N nitric acid followed by three consecutive rinses with deionized distilled water (a minimum of 1 L per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

4.5 pH Meters: The meter should be accurate to ± 0.05 units at 25 °C.

4.6 ZHE Extract Collection Devices: TEDLAR®[2] bags or glass, stainless steel or PTFE gas-tight syringes are used to collect the initial liquid phase and the final extract of the waste when using the ZHE device. The devices listed are recommended for use under the following conditions:

4.6.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), the TEDLAR® bag or a 600 mL syringe should be used to collect and combine the initial liquid and solid extract.

4.6.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

4.6.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5 mL of liquid expressed from the device. The remaining aliquots are used for analysis.

4.7 ZHE Extraction Fluid Transfer Devices: Any device capable of transferring the extraction fluid into the ZHE without changing the nature of the extraction fluid is acceptable (e.g., a positive displacement or peristaltic pump, a gas tight syringe, pressure filtration unit (see Section 4.3.2), or other ZHE device).

4.8 Laboratory Balance: Any laboratory balance accurate to within ± 0.01 grams may be used (all weight measurements are to be within ± 0.1 grams).

4.9 Beaker or Erlenmeyer flask, glass, 500 mL.

---

[2] TEDLAR® is a registered trademark of Du Pont.

4.10 Watchglass, appropriate diameter to cover beaker or Erlenmeyer flask.

4.11 Magnetic stirrer.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. Reagent water is defined as water in which an interferant is not observed at or above the method's detection limit of the analyte(s) of interest. For nonvolatile extractions, ASTM Type II water or equivalent meets the definition of reagent water. For volatile extractions, it is recommended that reagent water be generated by any of the following methods. Reagent water should be monitored periodically for impurities.

5.2.1 Reagent water for volatile extractions may be generated by passing tap water through a carbon filter bed containing about 500 grams of activated carbon (Calgon Corp., Filtrasorb-300 or equivalent).

5.2.2 A water purification system (Millipore Super-Q or equivalent) may also be used to generate reagent water for volatile extractions.

5.2.3 Reagent water for volatile extractions may also be prepared by boiling water for 15 minutes. Subsequently, while maintaining the water temperature at 90 $\pm$ 5 degrees C, bubble a contaminant-free inert gas (e.g. nitrogen) through the water for 1 hour. While still hot, transfer the water to a narrow mouth screw-cap bottle under zero-headspace and seal with a Teflon-lined septum and cap.

5.3 Hydrochloric acid (1N), HCl, made from ACS reagent grade.

5.4 Nitric acid (1N), HNO_3, made from ACS reagent grade.

5.5 Sodium hydroxide (1N), NaOH, made from ACS reagent grade.

5.6 Glacial acetic acid, CH_3CH_2OOH, ACS reagent grade.

5.7 Extraction fluid.

5.7.1 Extraction fluid # 1: Add 5.7 mL glacial CH_3CH_2OOH to 500 mL of reagent water (See Section 5.2), add 64.3 mL of 1N NaOH, and dilute to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 4.93 $\pm$ 0.05.

5.7.2 Extraction fluid # 2: Dilute 5.7 mL glacial CH_3CH_2OOH with reagent water (See Section 5.2) to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 2.88 $\pm$ 0.05.

NOTE: These extraction fluids should be monitored frequently for impurities. The pH should be checked prior to use to ensure that these fluids are made up accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

5.8 Analytical standards shall be prepared according to the appropriate analytical method.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples shall be collected using an appropriate sampling plan.

6.2 The TCLP may place requirements on the minimal size of the field sample, depending upon the physical state or states of the waste and the analytes of concern. An aliquot is needed for preliminary evaluation of which extraction fluid is to be used for the nonvolatile analyte extraction procedure. Another aliquot may be needed to actually conduct the nonvolatile extraction (see Section 1.4 concerning the use of this extract for volatile organics). If volatile organics are of concern, another aliquot may be needed. Quality control measures may require additional aliquots. Further, it is always wise to collect more sample just in case something goes wrong with the initial attempt to conduct the test.

6.3 Preservatives shall not be added to samples before extraction.

6.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

6.5 When the waste is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon-lined septum capped vials and stored at 4 °C. Samples should be opened only immediately prior to extraction).

6.6 TCLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for metallic analyte determinations must be acidified with nitric acid to a pH < 2, unless precipitation occurs (see Section 7.2.14 if precipitation occurs). Extracts should be preserved for other analytes according to the guidance given in the individual analysis methods. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses. See Section 8.0 (QA requirements) for acceptable sample and extract holding times.

7.0 PROCEDURE

7.1 Preliminary Evaluations

Perform preliminary TCLP evaluations on a minimum 100 gram aliquot of waste. This aliquot may not actually undergo TCLP extraction. These preliminary evaluations include: (1) determination of the percent solids (Section 7.1.1); (2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Section 7.1.2); (3) determination of whether the solid portion of the waste requires particle size reduction (Section 7.1.3); and (4) determination of which of the two extraction fluids are to be used for the nonvolatile TCLP extraction of the waste (Section 7.1.4).

7.1.1 Preliminary determination of percent solids: Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure, as described below.

7.1.1.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids) proceed to Section 7.1.3.

7.1.1.2 If the sample is liquid or multiphasic, liquid/solid separation to make a preliminary determination of percent solids is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.1.1.3 through 7.1.1.9.

7.1.1.3 Pre-weigh the filter and the container that will receive the filtrate.

7.1.1.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

7.1.1.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight.

7.1.1.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.1.1.7 Quantitatively transfer the waste sample to the filter holder (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room temperature then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.1.1.5 to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within any 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.1.1.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.1.1.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.1.1.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (see Section 7.1.1.3) from the total weight of the filtrate-filled container. Determine the weight of the solid phase of the waste sample by subtracting the weight of the liquid phase from the weight of the total waste sample, as determined in Section 7.1.1.5 or 7.1.1.7.

Record the weight of the liquid and solid phases. Calculate the percent solids as follows:

$$\text{Percent solids} = \frac{\text{Weight of solid (Section 7.1.1.9)}}{\text{Total weight of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2 If the percent solids determined in Section 7.1.1.9 is equal to or greater than 0.5%, then proceed either to Section 7.1.3 to

determine whether the solid material requires particle size reduction or to Section 7.1.2.1 if it is noticed that a small amount of the filtrate is entrained in wetting of the filter. If the percent solids determined in Section 7.1.1.9 is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed and to Section 7.3 with a fresh portion of the waste if the volatile TCLP is to be performed.

7.1.2.1 Remove the solid phase and filter from the filtration apparatus.

7.1.2.2 Dry the filter and solid phase at 100 ± 20 °C until two successive weighing yield the same value within ± 1%. Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. It is recommended that the drying oven be vented to a hood or other appropriate device.

7.1.2.3 Calculate the percent dry solids as follows:

$$\text{Percent dry solids} = \frac{\text{(Wt. of dry waste + filter) - tared wt. of filter}}{\text{Initial wt. of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed, and to Section 7.3 if the volatile TCLP is to be performed. If the percent dry solids is greater than or equal to 0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section (7.1) and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 7.1.3) and determine the appropriate extraction fluid (Section 7.1.4). If only the volatile TCLP is to be performed, see the note in Section 7.1.4.

7.1.3 Determination of whether the waste requires particle size reduction (particle size is reduced during this step): Using the solid portion of the waste, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1 cm^2, or is smaller than 1 cm in its narrowest dimension (i.e., is capable of passing through a 9.5 mm (0.375 inch) standard sieve). If the surface area is smaller or the particle size larger than described above, prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above. If the solids are prepared for organic volatiles extraction, special precautions must be taken (see Section 7.3.6).

NOTE: Surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet

the criteria, sample specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

7.1.4 Determination of appropriate extraction fluid: If the solid content of the waste is greater than or equal to 0.5% and if the sample will be extracted for nonvolatile constituents (Section 7.2), determine the appropriate fluid (Section 5.7) for the nonvolatiles extraction as follows:

NOTE: TCLP extraction for volatile constituents uses only extraction fluid #1 (Section 5.7.1). Therefore, if TCLP extraction for nonvolatiles is not required, proceed to Section 7.3.

7.1.4.1 Weigh out a small subsample of the solid phase of the waste, reduce the solid (if necessary) to a particle size of approximately 1 mm in diameter or less, and transfer 5.0 grams of the solid phase of the waste to a 500 mL beaker or Erlenmeyer flask.

7.1.4.2 Add 96.5 mL of reagent water to the beaker, cover with a watchglass, and stir vigorously for 5 minutes using a magnetic stirrer. Measure and record the pH. If the pH is <5.0, use extraction fluid #1. Proceed to Section 7.2.

7.1.4.3 If the pH from Section 7.1.4.2 is >5.0, add 3.5 mL 1N HCl, slurry briefly, cover with a watchglass, heat to 50 °C, and hold at 50 °C for 10 minutes.

7.1.4.4 Let the solution cool to room temperature and record the pH. If the pH is <5.0, use extraction fluid #1. If the pH is >5.0, use extraction fluid #2. Proceed to Section 7.2.

7.1.5 If the aliquot of the waste used for the preliminary evaluation (Sections 7.1.1 - 7.1.4) was determined to be 100% solid at Section 7.1.1.1, then it can be used for the Section 7.2 extraction (assuming at least 100 grams remain), and the Section 7.3 extraction (assuming at least 25 grams remain). If the aliquot was subjected to the procedure in Section 7.1.1.7, then another aliquot shall be used for the volatile extraction procedure in Section 7.3. The aliquot of the waste subjected to the procedure in Section 7.1.1.7 might be appropriate for use for the Section 7.2 extraction if an adequate amount of solid (as determined by Section 7.1.1.9) was obtained. The amount of solid necessary is dependent upon whether a sufficient amount of extract will be produced to support the analyses. If an adequate amount of solid remains, proceed to Section 7.2.10 of the nonvolatile TCLP extraction.

7.2 Procedure When Volatiles are not Involved

A minimum sample size of 100 grams (solid and liquid phases) is recommended. In some cases, a larger sample size may be appropriate, depending on the

solids content of the waste sample (percent solids, See Section 7.1.1), whether the initial liquid phase of the waste will be miscible with the aqueous extract of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough solids should be generated for extraction such that the volume of TCLP extract will be sufficient to support all of the analyses required. If the amount of extract generated by a single TCLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed and the extracts from each combined and aliquoted for analysis.

7.2.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid, see Section 7.1.1), weigh out a subsample of the waste (100 gram minimum) and proceed to Section 7.2.9.

7.2.2 If the sample is liquid or multiphasic, liquid/solid separation is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.2.3 to 7.2.8.

7.2.3 Pre-weigh the container that will receive the filtrate.

7.2.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 4.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

7.2.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight. If the waste contains <0.5% dry solids (Section 7.1.2), the liquid portion of the waste, after filtration, is defined as the TCLP extract. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required of the TCLP extract. For wastes containing >0.5% dry solids (Sections 7.1.1 or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size (100 gram minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP extract.

7.2.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the waste is centrifuged, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.2.7 Quantitatively transfer the waste sample (liquid and solid phases) to the filter holder (see Section 4.3.2). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at

room temperature, then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.2.5, to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.2.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase. Weigh the filtrate. The liquid phase may now be either analyzed (See Section 7.2.12) or stored at 4 °C until time of analysis.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.2.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the extraction as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.2.9 If the waste contains <0.5% dry solids (see Section 7.1.2), proceed to Section 7.2.13. If the waste contains >0.5% dry solids (see Section 7.1.1 or 7.1.2), and if particle size reduction of the solid was needed in Section 7.1.3, proceed to Section 7.2.10. If the waste as received passes a 9.5 mm sieve, quantitatively transfer the solid material into the extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to Section 7.2.11.

7.2.10 Prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described in Section 7.1.3. When the surface area or particle size has been appropriately altered, quantitatively transfer the solid

material into an extractor bottle. Include the filter used to separate the initial liquid from the solid phase.

NOTE: Sieving of the waste is not normally required. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended. If sieving is necessary, a Teflon coated sieve should be used to avoid contamination of the sample.

7.2.11 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.2.5 or 7.2.7)}}{100}$$

Slowly add this amount of appropriate extraction fluid (see Section 7.1.4) to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal), secure in rotary agitation device, and rotate at 30 ± 2 rpm for 18 ± 2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23 ± 2 °C during the extraction period.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically opened (e.g., after 15 minutes, 30 minutes, and 1 hour) and vented into a hood.

7.2.12 Following the 18 ± 2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter, as outlined in Section 7.2.7. For final filtration of the TCLP extract, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filter(s) shall be acid-washed (see Section 4.4) if evaluating the mobility of metals.

7.2.13 Prepare the TCLP extract as follows:

7.2.13.1 If the waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.2.12 is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.2 If compatible (e.g., multiple phases will not result on combination), combine the filtered liquid resulting from Section 7.2.12 with the initial liquid phase of the waste obtained in Section 7.2.7. This combined liquid is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.3 If the initial liquid phase of the waste, as obtained from Section 7.2.7, is not or may not be compatible with the filtered liquid resulting from Section 7.2.12, do not combine these liquids. Analyze these liquids, collectively defined as the TCLP extract, and combine the results mathematically, as described in Section 7.2.14.

7.2.14 Following collection of the TCLP extract, the pH of the extract should be recorded. Immediately aliquot and preserve the extract for analysis. Metals aliquots must be acidified with nitric acid to pH <2. If precipitation is observed upon addition of nitric acid to a small aliquot of the extract, then the remaining portion of the extract for metals analyses shall not be acidified and the extract shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4 °C) until analyzed. The TCLP extract shall be prepared and analyzed according to appropriate analytical methods. TCLP extracts to be analyzed for metals shall be acid digested except in those instances where digestion causes loss of metallic analytes. If an analysis of the undigested extract shows that the concentration of any regulated metallic analyte exceeds the regulatory level, then the waste is hazardous and digestion of the extract is not necessary. However, data on undigested extracts alone cannot be used to demonstrate that the waste is not hazardous. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to $\pm$ 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)\ (C_1) + (V_2)\ (C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.2.15 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

7.3 Procedure When Volatiles are Involved

Use the ZHE device to obtain TCLP extract for analysis of volatile compounds only. Extract resulting from the use of the ZHE shall not be used to evaluate the mobility of nonvolatile analytes (e.g., metals, pesticides, etc.).

The ZHE device has approximately a 500 mL internal capacity. The ZHE can thus accommodate a maximum of 25 grams of solid (defined as that fraction of a

sample from which no additional liquid may be forced out by an applied pressure of 50 psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

Charge the ZHE with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

Do not allow the waste, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Any manipulation of these materials should be done when cold (4 °C) to minimize loss of volatiles.

7.3.1 Pre-weigh the (evacuated) filtrate collection container (See Section 4.6) and set aside. If using a TEDLAR® bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis. The containers listed in Section 4.6 are recommended for use under the conditions stated in Sections 4.6.1 - 4.6.3.

7.3.2 Place the ZHE piston within the body of the ZHE (it may be helpful first to moisten the piston O-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move once the ZHE is charged with sample (based upon sample size requirements determined from Section 7.3, Section 7.1.1 and/or 7.1.2). Secure the gas inlet/outlet flange (bottom flange) onto the ZHE body in accordance with the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set liquid inlet/outlet flange (top flange) aside.

7.3.3 If the waste is 100% solid (see Section 7.1.1), weigh out a subsample (25 gram maximum) of the waste, record weight, and proceed to Section 7.3.5.

7.3.4 If the waste contains < 0.5% dry solids (Section 7.1.2), the liquid portion of waste, after filtration, is defined as the TCLP extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required. For wastes containing $\geq$ 0.5% dry solids (Sections 7.1.1 and/or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size to charge into the ZHE. The recommended sample size is as follows:

7.3.4.1 For wastes containing < 5% solids (see Section 7.1.1), weigh out a 500 gram subsample of waste and record the weight.

7.3.4.2 For wastes containing $\geq$ 5% solids (see Section 7.1.1), determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge ZHE} = \frac{25}{\text{percent solids (Section 7.1.1)}} \times 100$$

Weigh out a subsample of the waste of the appropriate size and record the weight.

7.3.5 If particle size reduction of the solid portion of the waste was required in Section 7.1.3, proceed to Section 7.3.6. If particle size reduction was not required in Section 7.1.3, proceed to Section 7.3.7.

7.3.6 Prepare the waste for extraction by crushing, cutting, or grinding the solid portion of the waste to a surface area or particle size as described in Section 7.1.3. Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4 °C prior to particle size reduction. The means used to effect particle size reduction must not generate heat in and of itself. If reduction of the solid phase of the waste is necessary, exposure of the waste to the atmosphere should be avoided to the extent possible.

NOTE: Sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended.

When the surface area or particle size has been appropriately altered, proceed to Section 7.3.7.

7.3.7 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

7.3.8 Quantitatively transfer the entire sample (liquid and solid phases) quickly to the ZHE. Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extract collection device to the top plate.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the ZHE, determine the weight of this residue and subtract it from the sample weight determined in Section 7.3.4 to determine the weight of the waste sample that will be filtered.

Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10 psi (or more if necessary) to force all headspace

slowly out of the ZHE device into a hood. At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm up to room temperature in the device before filtering. If the waste is 100% solid (see Section 7.1.1), slowly increase the pressure to a maximum of 50 psi to force most of the headspace out of the device and proceed to Section 7.3.12.

7.3.9 Attach the evacuated pre-weighed filtrate collection container to the liquid inlet/outlet valve and open the valve. Begin applying gentle pressure of 1-10 psi to force the liquid phase of the sample into the filtrate collection container. If no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When liquid flow has ceased such that continued pressure filtration at 50 psi does not result in any additional filtrate within a 2 minute period, stop the filtration. Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.3.10 The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying pressure filtration, this material will not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the TCLP extraction as a solid.

If the original waste contained <0.5% dry solids (see Section 7.1.2), this filtrate is defined as the TCLP extract and is analyzed directly. Proceed to Section 7.3.15.

7.3.11 The liquid phase may now be either analyzed immediately (See Sections 7.3.13 through 7.3.15) or stored at 4 °C under minimal headspace conditions until time of analysis. Determine the weight of extraction fluid #1 to add to the ZHE as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.3.4 or 7.3.8)}}{100}$$

7.3.12 The following Sections detail how to add the appropriate amount of extraction fluid to the solid material within the ZHE and agitation of the ZHE vessel. Extraction fluid #1 is used in all cases (See Section 5.7).

7.3.12.1 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid inlet/outlet valve. The line used shall contain fresh extraction fluid and should be preflushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device.

7.3.12.2 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device in an end-over-end fashion 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psi (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psi and check all ZHE fittings to ensure that they are closed.

7.3.12.3 Place the ZHE in the rotary agitation apparatus (if it is not already there) and rotate at 30 $\pm$ 2 rpm for 18 $\pm$ 2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23 $\pm$ 2 °C during agitation.

7.3.13 Following the 18 $\pm$ 2 hour agitation period, check the pressure behind the ZHE piston by quickly opening and closing the gas inlet/outlet valve and noting the escape of gas. If the pressure has not been maintained (i.e., no gas release observed), the device is leaking. Check the ZHE for leaking as specified in Section 4.2.1, and perform the extraction again with a new sample of waste. If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases. If the waste contained an initial liquid phase, the liquid may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combining would create multiple phases, or there is not enough volume left within the filtrate collection container. Filter through the glass fiber filter, using the ZHE device as discussed in Section 7.3.9. All extract shall be filtered and collected if the

TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase (see Sections 4.6 and 7.3.1).

NOTE: An in-line glass fiber filter may be used to filter the material within the ZHE if it is suspected that the glass fiber filter has been ruptured.

7.3.14 If the original waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.3.13 is defined as the TCLP extract. If the waste contained an initial liquid phase, the filtered liquid material obtained from Section 7.3.13 and the initial liquid phase (Section 7.3.9) are collectively defined as the TCLP extract.

7.3.15 Following collection of the TCLP extract, immediately prepare the extract for analysis and store with minimal headspace at 4 °C until analyzed. Analyze the TCLP extract according to the appropriate analytical methods. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phases (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.3.16 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

8.0 QUALITY ASSURANCE

8.1 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel.

8.2 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.) unless the result exceeds the regulatory level and the data are being used solely to demonstrate that the waste property exceeds the regulatory level. A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

8.2.1 Matrix spikes are to be added after filtration of the TCLP extract and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

8.2.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentration, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP extract as that which was analyzed for the unspiked sample.

8.2.3 The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist. Use of other internal calibration methods, modification of the analytical methods, or use of alternate analytical methods may be needed to accurately measure the analyte concentration in the TCLP extract when the recovery of the matrix spike is below the expected analytical method performance.

8.2.4 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%Recovery) = 100\ (X_s - X_u)/K$$

where:
X_s = measured value for the spiked sample,
X_u = measured value for the unspiked sample, and
K = known value of the spike in the sample.

8.3 All quality control measures described in the appropriate analytical methods shall be followed.

8.4 The use of internal calibration quantitation methods shall be employed for a metallic contaminant if: (1) Recovery of the contaminant from the TCLP extract is not at least 50% and the concentration does not exceed the regulatory level, and (2) The concentration of the contaminant measured in the extract is within 20% of the appropriate regulatory level.

8.4.1. The method of standard additions shall be employed as the internal calibration quantitation method for each metallic contaminant.

8.4.2 The method of standard additions requires preparing calibration standards in the sample matrix rather than reagent water or blank solution. It requires taking four identical aliquots of the solution and adding known amounts of standard to three of these aliquots. The forth aliquot is the unknown. Preferably, the first addition should be prepared so that the resulting concentration is approximately 50% of the expected concentration of the sample. The second and third additions should be prepared so that the concentrations are approximately 100% and

150% of the expected concentration of the sample. All four aliquots are maintained at the same final volume by adding reagent water or a blank solution, and may need dilution adjustment to maintain the signals in the linear range of the instrument technique. All four aliquots are analyzed.

8.4.3 Prepare a plot, or subject data to linear regression, of instrument signals or external-calibration-derived concentrations as the dependant variable (y-axis) versus concentrations of the additions of standard as the independent variable (x-axis). Solve for the intercept of the abscissa (the independent variable, x-axis) which is the concentration in the unknown.

8.4.4 Alternately, subtract the instrumental signal or external-calibration-derived concentration of the unknown (unspiked) sample from the instrumental signals or external-calibration-derived concentrations of the standard additions. Plot or subject to linear regression of the corrected instrument signals or external-calibration-derived concentrations as the dependant variable versus the independent variable. Derive concentrations for unknowns using the internal calibration curve as if it were an external calibration curve.

8.5 Samples must undergo TCLP extraction within the following time periods:

SAMPLE MAXIMUM HOLDING TIMES [DAYS]

	From: Field collection To: TCLP extraction	From: TCLP extraction To: Preparative extraction	From: Preparative extraction To: Determinative analysis	Total elapsed time
Volatiles	14	NA	14	28
Semi-volatiles	14	7	40	61
Mercury	28	NA	28	56
Metals, except mercury	180	NA	180	360

NA = Not applicable

If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding the holding time is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory level.

9.0 METHOD PERFORMANCE

9.1 Ruggedness. Two ruggedness studies have been performed to determine the effect of various perturbations on specific elements of the TCLP protocol. Ruggedness testing determines the sensitivity of small procedural variations which might be expected to occur during routine laboratory application.

9.1.1 Metals - The following conditions were used when leaching a waste for metals analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Extraction time	16 hours vs. 18 hours
Headspace	20% vs. 60%
Buffer #2 acidity	190 meq vs. 210 meq
Acid-washed filters	yes vs. no
Filter type	0.7 µm glass fiber vs. 0.45 µm vs. polycarbonate
Bottle type	borosilicate vs. flint glass

Of the seven method variations examined, acidity of the extraction fluid had the greatest impact on the results. Four of 13 metals from an API separator sludge/electroplating waste (API/EW) mixture and two of three metals from an ammonia lime still bottom waste were extracted at higher levels by the more acidic buffer. Because of the sensitivity to pH changes, the method requires that the extraction fluids be prepared so that the final pH is within $\pm$ 0.05 units as specified.

9.1.2 Volatile Organic Compounds - The following conditions were used when leaching a waste for VOC analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Headspace	0% vs. 5%
Buffer #1 acidity	60 meq vs. 80 meq
Method of storing extract	Syringe vs. Tedlar® bag
Aliquotting	yes vs. no
Pressure behind piston	0 psi vs. 20 psi

None of the parameters had a significant effect on the results of the ruggedness test.

9.2 Precision. Many TCLP precision (reproducibility) studies have been performed, and have shown that, in general, the precision of the TCLP is comparable to or exceeds that of the EP toxicity test and that method precision is adequate. One of the more significant contributions to poor precision appears to be related to sample homogeneity and inter-laboratory variation (due to the nature of waste materials).

9.2.1 Metals - The results of a multi-laboratory study are shown in Table 6, and indicate that a single analysis of a waste may not be adequate for waste characterization and identification requirements.

9.2.2 Semi-Volatile Organic Compounds - The results of two studies are shown in Tables 7 and 8. Single laboratory precision was excellent with greater than 90 percent of the results exhibiting an RSD less than 25 percent. Over 85 percent of all individual compounds in the multi-laboratory study fell in the RSD range of 20 - 120 percent. Both studies concluded that the TCLP provides adequate precision. It was also determined that the high acetate content of the extraction fluid did not present problems (i.e., column degradation of the gas chromatograph) for the analytical conditions used.

9.2.3 Volatile Organic Compounds - Eleven laboratories participated in a collaborative study of the use of the ZHE with two waste types which were fortified with a mixture of VOCs. The results of the collaborative study are shown in Table 9. Precision results for VOCs tend to occur over a considerable range. However, the range and mean RSD compared very closely to the same collaborative study metals results in Table 6. Blackburn and Show concluded that at the 95% level of significance: 1) recoveries among laboratories were statistically similar, 2) recoveries did not vary significantly between the two sample types, and 3) each laboratory showed the same pattern of recovery for each of the two samples.

Suitable Zero-Headspace Extractor Vessels[1]

Company	Location	Model No.
Analytical Testing & Consulting Services, Inc.	Warrington, PA (215) 343-4490	C1O2, Mechanical Pressure Device
Associated Design and Manufacturing Company	Alexandria, VA (703) 549-5999	3745-ZHE, Gas Pressure Device
Lars Lande Manufacturing[2]	Whitmore Lake, MI (313) 449-4116	ZHE-11, Gas Pressure Device
Millipore Corporation	Bedford, MA (800) 225-3384	YT30O9OHW, Gas Pressure Device
Environmental Machine and Design, Inc.	Lynchburg, VA (804) 845-6424	VOLA-TOX1, Gas Pressure Device
Gelman Science	Ann Arbor, MI (800) 521-1520	15400 Gas Pressure Device

[1] Any device that meets the specifications listed in Section 4.2.1 of the method is suitable.

[2] This device uses a 110 mm filter.

Table 4.
Suitable Filter Holders[1]

Company	Location	Model/ Catalogue No.	Size
Nucleopore Corporation	Pleasanton, CA (800) 882-7711	425910 410400	142 mm 47 mm
Micro Filtration Systems	Dublin, CA (800) 334-7132 (415) 828-6010	302400 311400	142 mm 47 mm
Millipore Corporation	Bedford, MA (800) 225-3384	YT30142HW XX1004700	142 mm 47 mm

[1] Any device capable of separating the liquid from the solid phase of the waste is suitable, providing that it is chemically compatible with the waste and the constituents to be analyzed. Plastic devices (not listed above) may be used when only inorganic analytes are of concern. The 142 mm size filter holder is recommended.

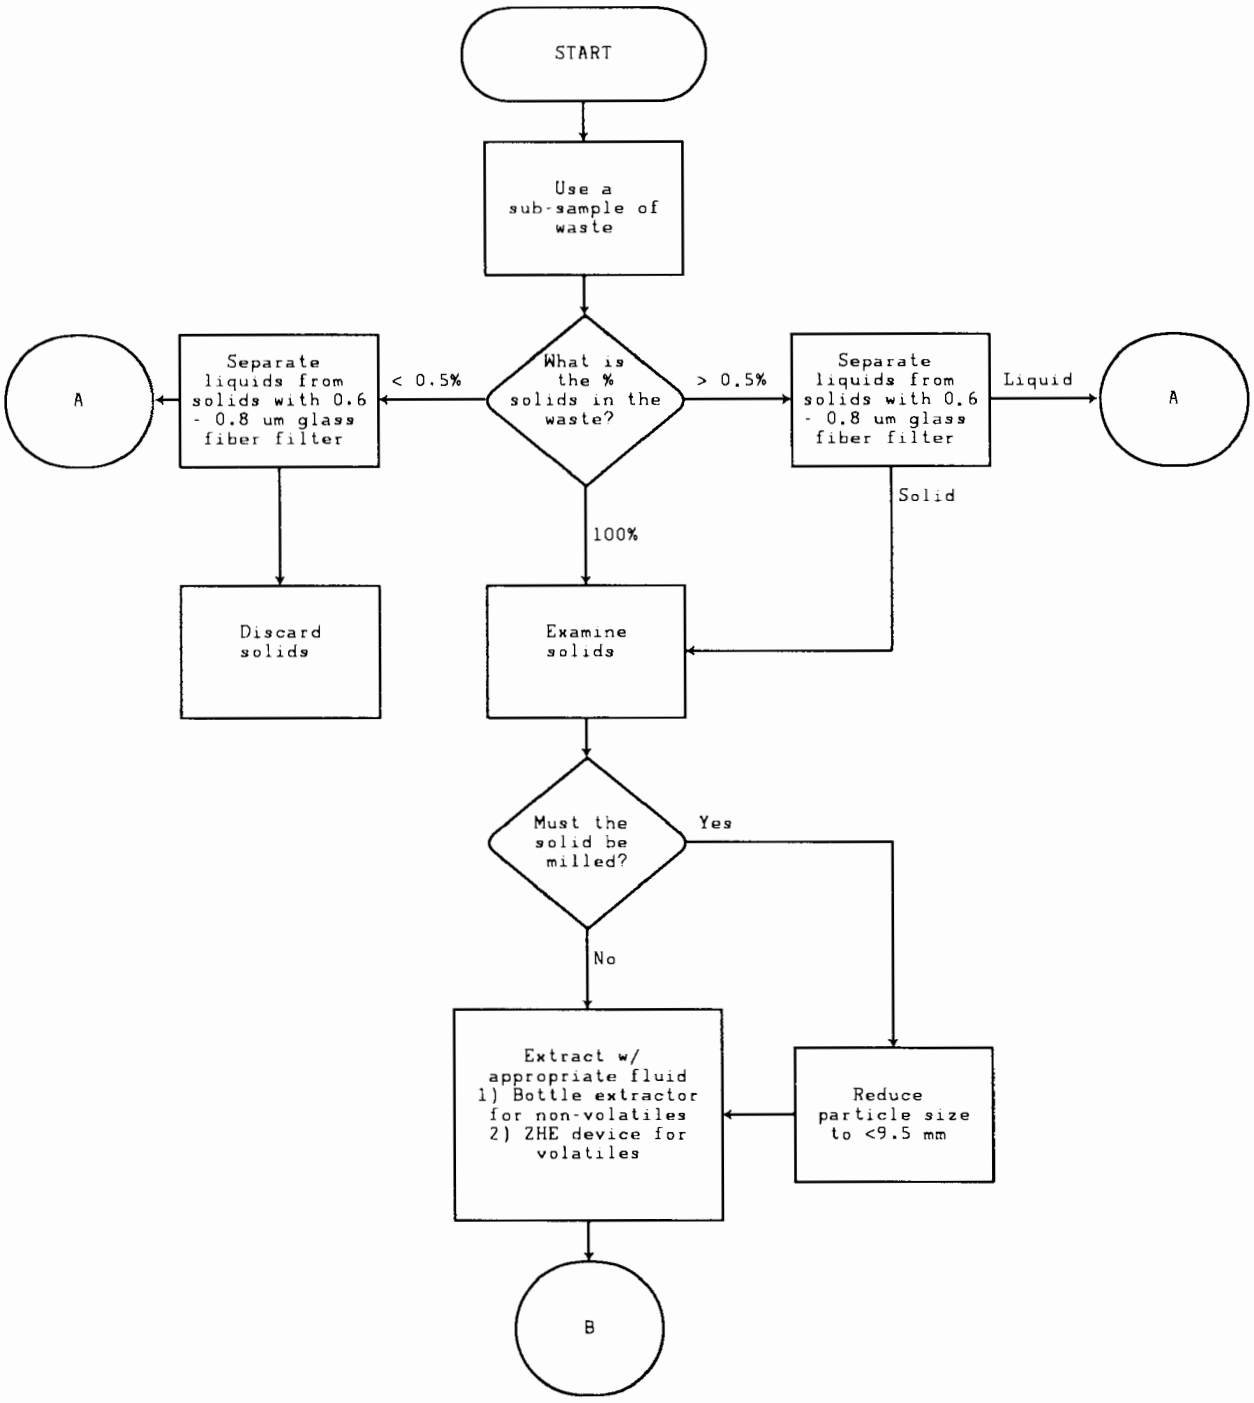
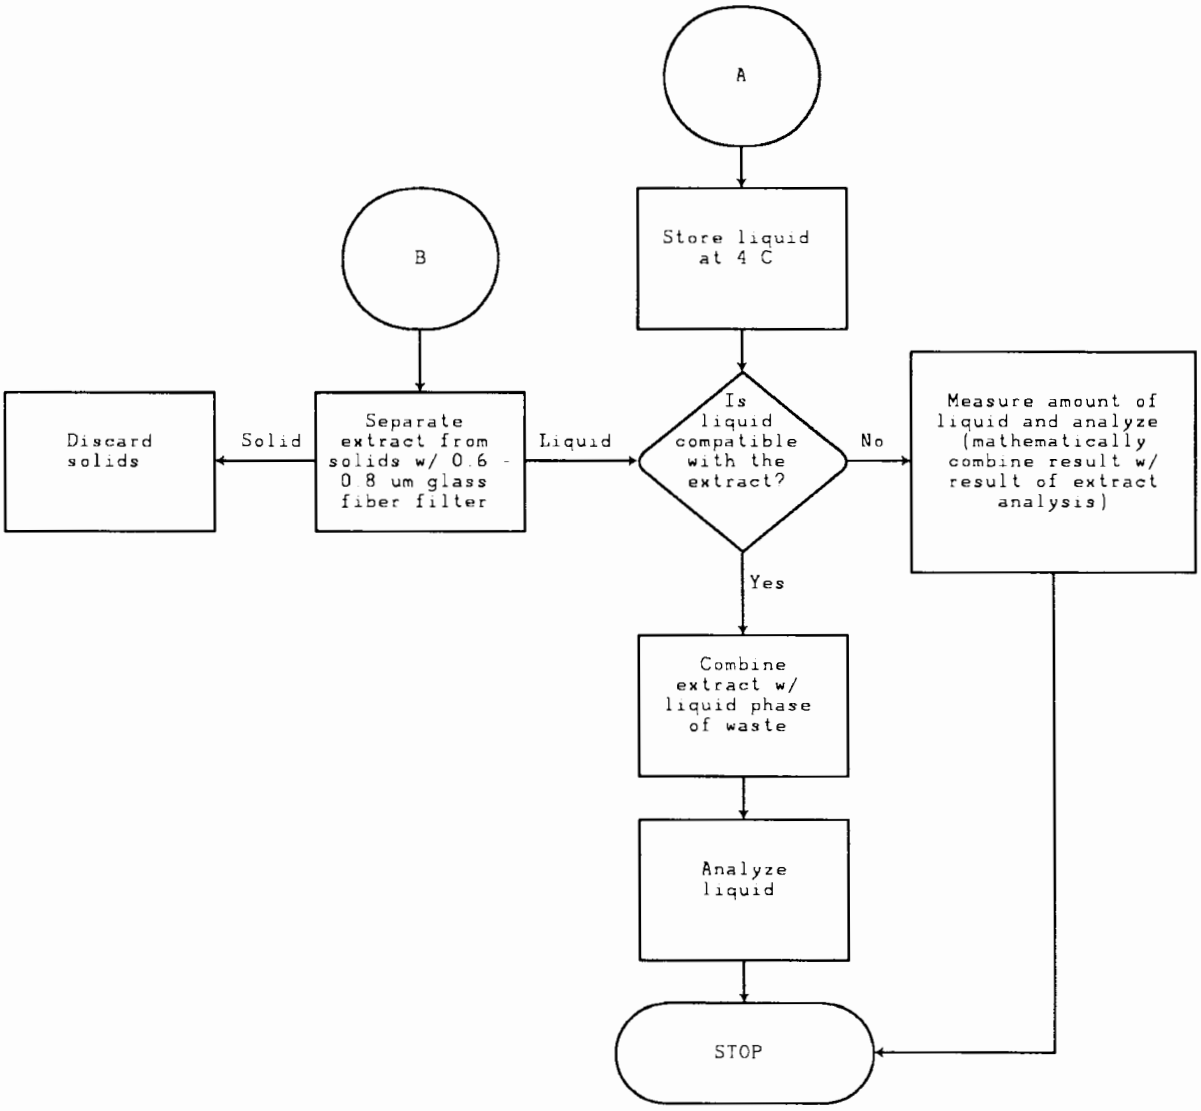
TOXICITY CHARACTERISTIC LEACHATE PROCEDURE



TOXICITY CHARACTERISTIC LEACHATE PROCEDURE



METHOD 1312

SYNTHETIC PRECIPITATION LEACHING PROCEDURE

1.0 SCOPE AND APPLICATION

1.1 Method 1312 is designed to determine the mobility of both organic and inorganic analytes present in liquids, soils, and wastes.

2.0 SUMMARY OF METHOD

2.1 For liquid samples (i.e., those containing less than 0.5 % dry solid material), the sample, after filtration through a 0.6 to 0.8 μm glass fiber filter, is defined as the 1312 extract.

2.2 For samples containing greater than 0.5 % solids, the liquid phase, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the region of the country where the sample site is located if the sample is a soil. If the sample is a waste or wastewater, the extraction fluid employed is a pH 4.2 solution. A special extractor vessel is used when testing for volatile analytes (see Table 1 for a list of volatile compounds). Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 μm glass fiber filter.

2.3 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3.0 INTERFERENCES

3.1 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.0 APPARATUS AND MATERIALS

4.1 Agitation apparatus: The agitation apparatus must be capable of rotating the extraction vessel in an end-over-end fashion (see Figure 1) at 30 ± 2 rpm. Suitable devices known to EPA are identified in Table 2.

4.2 Extraction Vessels

4.2.1 Zero Headspace Extraction Vessel (ZHE). This device is for use only when the sample is being tested for the mobility of volatile analytes (i.e., those listed in Table 1). The ZHE (depicted in Figure 2) allows for liquid/solid separation within the device and effectively precludes headspace. This type of vessel allows for initial liquid/solid

separation, extraction, and final extract filtration without opening the vessel (see Step 4.3.1). These vessels shall have an internal volume of 500-600 mL and be equipped to accommodate a 90-110 mm filter. The devices contain VITON®[1] O-rings which should be replaced frequently. Suitable ZHE devices known to EPA are identified in Table 3.

For the ZHE to be acceptable for use, the piston within the ZHE should be able to be moved with approximately 15 psig or less. If it takes more pressure to move the piston, the O-rings in the device should be replaced. If this does not solve the problem, the ZHE is unacceptable for 1312 analyses and the manufacturer should be contacted.

The ZHE should be checked for leaks after every extraction. If the device contains a built-in pressure gauge, pressurize the device to 50 psig, allow it to stand unattended for 1 hour, and recheck the pressure. If the device does not have a built-in pressure gauge, pressurize the device to 50 psig, submerge it in water, and check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted.

Some ZHEs use gas pressure to actuate the ZHE piston, while others use mechanical pressure (see Table 3). Whereas the volatiles procedure (see Step 7.3) refers to pounds-per-square-inch (psig), for the mechanically actuated piston, the pressure applied is measured in torque-inch-pounds. Refer to the manufacturer's instructions as to the proper conversion.

4.2.2 Bottle Extraction Vessel. When the sample is being evaluated using the nonvolatile extraction, a jar with sufficient capacity to hold the sample and the extraction fluid is needed. Headspace is allowed in this vessel.

The extraction bottles may be constructed from various materials, depending on the analytes to be analyzed and the nature of the waste (see Step 4.3.3). It is recommended that borosilicate glass bottles be used instead of other types of glass, especially when inorganics are of concern. Plastic bottles, other than polytetrafluoroethylene, shall not be used if organics are to be investigated. Bottles are available from a number of laboratory suppliers. When this type of extraction vessel is used, the filtration device discussed in Step 4.3.2 is used for initial liquid/solid separation and final extract filtration.

4.3 Filtration Devices: It is recommended that all filtrations be performed in a hood.

4.3.1 Zero-Headspace Extraction Vessel (ZHE): When the sample is evaluated for volatiles, the zero-headspace extraction vessel described

---

[1]VITON® is a trademark of Du Pont.

in Step 4.2.1 is used for filtration. The device shall be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50 psig).

NOTE: When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE.

4.3.2 Filter Holder: When the sample is evaluated for other than volatile analytes, a filter holder capable of supporting a glass fiber filter and able to withstand the pressure needed to accomplish separation may be used. Suitable filter holders range from simple vacuum units to relatively complex systems capable of exerting pressures of up to 50 psig or more. The type of filter holder used depends on the properties of the material to be filtered (see Step 4.3.3). These devices shall have a minimum internal volume of 300 mL and be equipped to accommodate a minimum filter size of 47 mm (filter holders having an internal capacity of 1.5 L or greater, and equipped to accommodate a 142 mm diameter filter, are recommended). Vacuum filtration can only be used for wastes with low solids content (<10 %) and for highly granular, liquid-containing wastes. All other types of wastes should be filtered using positive pressure filtration. Suitable filter holders known to EPA are listed in Table 4.

4.3.3 Materials of Construction: Extraction vessels and filtration devices shall be made of inert materials which will not leach or absorb sample components of interest. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high-density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) may be used only when evaluating the mobility of metals. Borosilicate glass bottles are recommended for use over other types of glass bottles, especially when inorganics are analytes of concern.

4.4 Filters: Filters shall be made of borosilicate glass fiber, shall contain no binder materials, and shall have an effective pore size of 0.6 to 0.8-μm . Filters known to EPA which meet these specifications are identified in Table 5. Pre-filters must not be used. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1N nitric acid followed by three consecutive rinses with reagent water (a minimum of 1-L per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

4.5 pH Meters: The meter should be accurate to $\pm$ 0.05 units at 25°C.

4.6 ZHE Extract Collection Devices: TEDLAR®[2] bags or glass, stainless steel or PTFE gas-tight syringes are used to collect the initial liquid phase and the final extract when using the ZHE device. These devices listed are recommended for use under the following conditions:

[2]TEDLAR® is a registered trademark of Du Pont.

4.6.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1 % of total waste), the TEDLAR® bag or a 600 mL syringe should be used to collect and combine the initial liquid and solid extract.

4.6.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1 % of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

4.6.3 If the waste contains no initial liquid phase (is 100 % solid) or has no significant solid phase (is <0.5% solid) , either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5 mL of liquid expressed from the device. The remaining aliquots are used for analysis.

4.7 ZHE Extraction Fluid Transfer Devices: Any device capable of transferring the extraction fluid into the ZHE without changing the nature of the extraction fluid is acceptable (e.g., a positive displacement or peristaltic pump, a gas-tight syringe, pressure filtration unit (see Step 4.3.2), or other ZHE device).

4.8 Laboratory Balance: Any laboratory balance accurate to within ± 0.01 grams may be used (all weight measurements are to be within ± 0.1 grams).

4.9 Beaker or Erlenmeyer flask, glass, 500 mL.

4.10 Watchglass, appropriate diameter to cover beaker or Erlenmeyer flask.

4.11 Magnetic stirrer.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. Reagent water is defined as water in which an interferant is not observed at or above the method's detection limit of the analyte(s) of interest. For nonvolatile extractions, ASTM Type II water or equivalent meets the definition of reagent water. For volatile extractions, it is recommended that reagent water be generated by any of the following methods. Reagent water should be monitored periodically for impurities.

5.2.1 Reagent water for volatile extractions may be generated by passing tap water through a carbon filter bed containing about 500 grams of activated carbon (Calgon Corp., Filtrasorb-300 or equivalent).

5.2.2 A water purification system (Millipore Super-Q or equivalent) may also be used to generate reagent water for volatile extractions.

5.2.3 Reagent water for volatile extractions may also be prepared by boiling water for 15 minutes. Subsequently, while maintaining the water temperature at 90 ± 5 degrees C, bubble a contaminant-free inert gas (e.g. nitrogen) through the water for 1 hour. While still hot, transfer the water to a narrow mouth screw-cap bottle under zero-headspace and seal with a Teflon-lined septum and cap.

5.3 Sulfuric acid/nitric acid (60/40 weight percent mixture) H_2SO_4/HNO_3. Cautiously mix 60 g of concentrated sulfuric acid with 40 g of concentrated nitric acid. If preferred, a more dilute H_2SO_4/HNO_3 acid mixture may be prepared and used in steps 5.4.1 and 5.4.2 making it easier to adjust the pH of the extraction fluids.

5.4 Extraction fluids.

5.4.1 Extraction fluid #1: This fluid is made by adding the 60/40 weight percent mixture of sulfuric and nitric acids (or a suitable dilution) to reagent water (Step 5.2) until the pH is 4.20 ± 0.05. The fluid is used to determine the leachability of soil from a site that is east of the Mississippi River, and the leachability of wastes and wastewaters.

NOTE: Solutions are unbuffered and exact pH may not be attained.

5.4.2 Extraction fluid #2: This fluid is made by adding the 60/40 weight percent mixture of sulfuric and nitric acids (or a suitable dilution) to reagent water (Step 5.2) until the pH is 5.00 ± 0.05. The fluid is used to determine the leachability of soil from a site that is west of the Mississippi River.

5.4.3 Extraction fluid #3: This fluid is reagent water (Step 5.2) and is used to determine cyanide and volatiles leachability.

NOTE: These extraction fluids should be monitored frequently for impurities. The pH should be checked prior to use to ensure that these fluids are made up accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

5.5 Analytical standards shall be prepared according to the appropriate analytical method.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples shall be collected using an appropriate sampling plan.

6.2 There may be requirements on the minimal size of the field sample depending upon the physical state or states of the waste and the analytes of concern. An aliquot is needed for the preliminary evaluations of the percent

solids and the particle size. An aliquot may be needed to conduct the nonvolatile analyte extraction procedure. If volatile organics are of concern, another aliquot may be needed. Quality control measures may require additional aliquots. Further, it is always wise to collect more sample just in case something goes wrong with the initial attempt to conduct the test.

6.3 Preservatives shall not be added to samples before extraction.

6.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

6.5 When the sample is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon-lined septum capped vials and stored at 4°C. Samples should be opened only immediately prior to extraction).

6.6 1312 extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for metallic analyte determinations must be acidified with nitric acid to a pH < 2, unless precipitation occurs (see Step 7.2.14 if precipitation occurs). Extracts should be preserved for other analytes according to the guidance given in the individual analysis methods. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses. See Step 8.0 (Quality Control) for acceptable sample and extract holding times.

7.0 PROCEDURE

7.1 Preliminary Evaluations

Perform preliminary 1312 evaluations on a minimum 100 gram aliquot of sample. This aliquot may not actually undergo 1312 extraction. These preliminary evaluations include: (1) determination of the percent solids (Step 7.1.1); (2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Step 7.1.2); and (3) determination of whether the solid portion of the waste requires particle size reduction (Step 7.1.3).

7.1.1 Preliminary determination of percent solids: Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure, as described below.

7.1.1.1 If the sample will obviously yield no free liquid when subjected to pressure filtration (i.e., is 100% solid), weigh out a representative subsample (100 g minimum) and proceed to Step 7.1.3.

7.1.1.2 If the sample is liquid or multiphasic, liquid/solid separation to make a preliminary determination of percent solids is required. This involves the filtration device

discussed in Step 4.3.2, and is outlined in Steps 7.1.1.3 through 7.1.1.9.

7.1.1.3 Pre-weigh the filter and the container that will receive the filtrate.

7.1.1.4 Assemble filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

7.1.1.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight.

7.1.1.6 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.1.1.7 Quantitatively transfer the sample to the filter holder (liquid and solid phases). Spread the sample evenly over the surface of the filter. If filtration of the waste at 4°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm up to room temperature in the device before filtering.

Gradually apply vacuum or gentle pressure of 1-10 psig, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psig, and if no additional liquid has passed through the filter in any 2-minute interval, slowly increase the pressure in 10 psig increments to a maximum of 50 psig. After each incremental increase of 10 psig, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2-minute interval, proceed to the next 10-psig increment. When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50 psig (i.e., filtration does not result in any additional filtrate within any 2-minute period), stop the filtration.

NOTE: If sample material (>1 % of original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Step 7.1.1.5 to determine the weight of the sample that will be filtered.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.1.1.8 The material in the filter holder is defined as the solid phase of the sample, and the filtrate is defined as the liquid phase.

NOTE: Some samples, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid, but even after applying vacuum or pressure filtration, as outlined in Step 7.1.1.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.1.1.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (see Step 7.1.1.3) from the total weight of the filtrate-filled container. Determine the weight of the solid phase of the sample by subtracting the weight of the liquid phase from the weight of the total sample, as determined in Step 7.1.1.5 or 7.1.1.7.

Record the weight of the liquid and solid phases. Calculate the percent solids as follows:

$$\text{Percent solids} = \frac{\text{Weight of solid (Step 7.1.1.9)}}{\text{Total weight of waste (Step 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2 If the percent solids determined in Step 7.1.1.9 is equal to or greater than 0.5%, then proceed either to Step 7.1.3 to determine whether the solid material requires particle size reduction or to Step 7.1.2.1 if it is noticed that a small amount of the filtrate is entrained in wetting of the filter. If the percent solids determined in Step 7.1.1.9 is less than 0.5%, then proceed to Step 7.2.9 if the nonvolatile 1312 analysis is to be performed, and to Step 7.3 with a fresh portion of the waste if the volatile 1312 analysis is to be performed.

7.1.2.1 Remove the solid phase and filter from the filtration apparatus.

7.1.2.2 Dry the filter and solid phase at 100 $\pm$ 20°C until two successive weighings yield the same value within $\pm$ 1 %. Record the final weight.

Caution: The drying oven should be vented to a hood or other appropriate device to eliminate the possibility of fumes from the sample escaping into the laboratory. Care should be taken to ensure that the sample will not flash or violently react upon heating.

7.1.2.3 Calculate the percent dry solids as follows:

$$\text{Percent dry solids} = \frac{\text{(Weight of dry sample + filter) - tared weight of filter}}{\text{Initial weight of sample (Step 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Step 7.2.9 if the nonvolatile 1312 analysis is to be performed, and to Step 7.3 if the volatile 1312 analysis is to be performed. If the percent dry solids is greater than or equal to 0.5%, and if the nonvolatile 1312 analysis is to be performed, return to the beginning of this Step (7.1) and, with a fresh portion of sample, determine whether particle size reduction is necessary (Step 7.1.3).

7.1.3 Determination of whether the sample requires particle-size reduction (particle-size is reduced during this step): Using the solid portion of the sample, evaluate the solid for particle size. Particle-size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1 cm^2, or is smaller than 1 cm in its narrowest dimension (i.e., is capable of passing through a 9.5 mm (0.375 inch) standard sieve). If the surface area is smaller or the particle size larger than described above, prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above. If the solids are prepared for organic volatiles extraction, special precautions must be taken (see Step 7.3.6).

NOTE: Surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, sample-specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

7.1.4 Determination of appropriate extraction fluid:

7.1.4.1 For soils, if the sample is from a site that is east of the Mississippi River, extraction fluid #1 should be used. If the sample is from a site that is west of the Mississippi River, extraction fluid #2 should be used.

7.1.4.2 For wastes and wastewater, extraction fluid #1 should be used.

7.1.4.3 For cyanide-containing wastes and/or soils, extraction fluid #3 (reagent water) must be used because leaching of cyanide-containing samples under acidic conditions may result in the formation of hydrogen cyanide gas.

7.1.5 If the aliquot of the sample used for the preliminary evaluation (Steps 7.1.1 - 7.1.4) was determined to be 100% solid at Step 7.1.1.1, then it can be used for the Step 7.2 extraction (assuming at least 100 grams remain), and the Step 7.3 extraction (assuming at least 25 grams remain). If the aliquot was subjected to the procedure in Step 7.1.1.7, then another aliquot shall be used for the volatile extraction procedure in Step 7.3. The aliquot of the waste subjected to the procedure in Step 7.1.1.7 might be appropriate for use for the Step 7.2 extraction if an adequate amount of solid (as determined by Step 7.1.1.9)

was obtained. The amount of solid necessary is dependent upon whether a sufficient amount of extract will be produced to support the analyses. If an adequate amount of solid remains, proceed to Step 7.2.10 of the nonvolatile 1312 extraction.

7.2 Procedure When Volatiles Are Not Involved

A minimum sample size of 100 grams (solid and liquid phases) is recommended. In some cases, a larger sample size may be appropriate, depending on the solids content of the waste sample (percent solids, See Step 7.1.1), whether the initial liquid phase of the waste will be miscible with the aqueous extract of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough solids should be generated for extraction such that the volume of 1312 extract will be sufficient to support all of the analyses required. If the amount of extract generated by a single 1312 extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed and the extracts from each combined and aliquoted for analysis.

7.2.1 If the sample will obviously yield no liquid when subjected to pressure filtration (i.e., is 100 % solid, see Step 7.1.1), weigh out a subsample of the sample (100 gram minimum) and proceed to Step 7.2.9.

7.2.2 If the sample is liquid or multiphasic, liquid/solid separation is required. This involves the filtration device described in Step 4.3.2 and is outlined in Steps 7.2.3 to 7.2.8.

7.2.3 Pre-weigh the container that will receive the filtrate.

7.2.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Step 4.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

7.2.5 Weigh out a subsample of the sample (100 gram minimum) and record the weight. If the waste contains <0.5 % dry solids (Step 7.1.2), the liquid portion of the waste, after filtration, is defined as the 1312 extract. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required of the 1312 extract. For wastes containing >0.5 % dry solids (Steps 7.1.1 or 7.1.2), use the percent solids information obtained in Step 7.1.1 to determine the optimum sample size (100 gram minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the 1312 extract.

7.2.6 Allow slurries to stand to permit the solid phase to settle. Samples that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the sample is centrifuged, the liquid should be decanted and filtered followed by

filtration of the solid portion of the waste through the same filtration system.

7.2.7 Quantitatively transfer the sample (liquid and solid phases) to the filter holder (see Step 4.3.2). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4°C reduces the amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm up to room temperature in the device before filtering.

Gradually apply vacuum or gentle pressure of 1-10 psig, until air or pressurizing gas moves through the filter. If this point if not reached under 10 psig, and if no additional liquid has passed through the filter in any 2-minute interval, slowly increase the pressure in 10-psig increments to maximum of 50 psig. After each incremental increase of 10 psig, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2-minute interval, proceed to the next 10-psig increment. When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50 psig (i.e., filtration does not result in any additional filtrate within a 2-minute period), stop the filtration.

NOTE: If waste material (>1 % of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Step 7.2.5, to determine the weight of the waste sample that will be filtered.

NOTE:Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.2.8 The material in the filter holder is defined as the solid phase of the sample, and the filtrate is defined as the liquid phase. Weigh the filtrate. The liquid phase may now be either analyzed (see Step 7.2.12) or stored at 4°C until time of analysis.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material which appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Step 7.2.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid, and is carried through the extraction as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.2.9 If the sample contains <0.5% dry solids (see Step 7.1.2), proceed to Step 7.2.13. If the sample contains >0.5 % dry solids (see Step 7.1.1 or 7.1.2), and if particle-size reduction of the solid was needed in Step 7.1.3, proceed to Step 7.2.10. If the sample as received passes a 9.5 mm sieve, quantitatively transfer the solid material into the extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to Step 7.2.11.

7.2.10 Prepare the solid portion of the sample for extraction by crushing, cutting, or grinding the waste to a surface area or particle-size as described in Step 7.1.3. When the surface area or particle-size has been appropriately altered, quantitatively transfer the solid material into an extractor bottle. Include the filter used to separate the initial liquid from the solid phase.

NOTE: Sieving of the waste is not normally required. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended. If sieving is necessary, a Teflon-coated sieve should be used to avoid contamination of the sample.

7.2.11 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \%\ \text{solids (Step 7.1.1)} \times \text{weight of waste filtered (Step 7.2.5 or 7.2.7)}}{100}$$

Slowly add this amount of appropriate extraction fluid (see Step 7.1.4) to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal), secure in rotary extractor device, and rotate at 30 ± 2 rpm for 18 ± 2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23 ± 2°C during the extraction period.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of sample (e.g., limed or calcium carbonate-containing sample may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically opened (e.g., after 15 minutes, 30 minutes, and 1 hour) and vented into a hood.

7.2.12 Following the 18 ± 2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter, as outlined in Step 7.2.7. For final filtration of the 1312 extract, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filter(s) shall be acid-washed (see Step 4.4) if evaluating the mobility of metals.

7.2.13 Prepare the 1312 extract as follows:

7.2.13.1 If the sample contained no initial liquid phase, the filtered liquid material obtained from Step 7.2.12 is defined as the 1312 extract. Proceed to Step 7.2.14.

7.2.13.2 If compatible (e.g., multiple phases will not result on combination), combine the filtered liquid resulting from Step 7.2.12 with the initial liquid phase of the sample obtained

in Step 7.2.7. This combined liquid is defined as the 1312 extract. Proceed to Step 7.2.14.

7.2.13.3 If the initial liquid phase of the waste, as obtained from Step 7.2.7, is not or may not be compatible with the filtered liquid resulting from Step 7.2.12, do not combine these liquids. Analyze these liquids, collectively defined as the 1312 extract, and combine the results mathematically, as described in Step 7.2.14.

7.2.14 Following collection of the 1312 extract, the pH of the extract should be recorded. Immediately aliquot and preserve the extract for analysis. Metals aliquots must be acidified with nitric acid to pH < 2. If precipitation is observed upon addition of nitric acid to a small aliquot of the extract, then the remaining portion of the extract for metals analyses shall not be acidified and the extract shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4°C) until analyzed. The 1312 extract shall be prepared and analyzed according to appropriate analytical methods. 1312 extracts to be analyzed for metals shall be acid digested except in those instances where digestion causes loss of metallic analytes. If an analysis of the undigested extract shows that the concentration of any regulated metallic analyte exceeds the regulatory level, then the waste is hazardous and digestion of the extract is not necessary. However, data on undigested extracts alone cannot be used to demonstrate that the waste is not hazardous. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to $\pm$ 0.5 %), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)\,(C_1) + (V_2)\,(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.2.15 Compare the analyte concentrations in the 1312 extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

7.3 Procedure When Volatiles Are Involved

Use the ZHE device to obtain 1312 extract for analysis of volatile compounds only. Extract resulting from the use of the ZHE shall not be used to evaluate the mobility of non-volatile analytes (e.g., metals, pesticides, etc.).

The ZHE device has approximately a 500 mL internal capacity. The ZHE can thus accommodate a maximum of 25 grams of solid (defined as that fraction of a sample from which no additional liquid may be forced out by an applied pressure of 50 psig), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

Charge the ZHE with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

Do not allow the sample, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Any manipulation of these materials should be done when cold (4°C) to minimize loss of volatiles.

7.3.1 Pre-weigh the (evacuated) filtrate collection container (see Step 4.6) and set aside. If using a TEDLAR® bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis. The containers listed in Step 4.6 are recommended for use under the conditions stated in Steps 4.6.1-4.6.3.

7.3.2 Place the ZHE piston within the body of the ZHE (it may be helpful first to moisten the piston O-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move once the ZHE is charged with sample (based upon sample size requirements determined from Step 7.3, Step 7.1.1 and/or 7.1.2). Secure the gas inlet/outlet flange (bottom flange) onto the ZHE body in accordance with the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set liquid inlet/outlet flange (top flange) aside.

7.3.3 If the sample is 100% solid (see Step 7.1.1), weigh out a subsample (25 gram maximum) of the waste, record weight, and proceed to Step 7.3.5.

7.3.4 If the sample contains <0.5% dry solids (Step 7.1.2), the liquid portion of waste, after filtration, is defined as the 1312 extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required. For samples containing $\geq$0.5% dry solids (Steps 7.1.1 and/or 7.1.2), use the percent solids information obtained in Step 7.1.1 to determine the optimum sample size to charge into the ZHE. The recommended sample size is as follows:

7.3.4.1 For samples containing <5% solids (see Step 7.1.1), weigh out a 500 gram subsample of waste and record the weight.

7.3.4.2 For wastes containing >5% solids (see Step 7.1.1), determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge ZHE} = \frac{25}{\text{percent solids (Step 7.1.1)}} \times 100$$

Weigh out a subsample of the waste of the appropriate size and record the weight.

7.3.5 If particle-size reduction of the solid portion of the sample was required in Step 7.1.3, proceed to Step 7.3.6. If particle-size reduction was not required in Step 7.1.3, proceed to Step 7.3.7.

7.3.6 Prepare the sample for extraction by crushing, cutting, or grinding the solid portion of the waste to a surface area or particle size as described in Step 7.1.3.1. Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4°C prior to particle-size reduction. The means used to effect particle-size reduction must not generate heat in and of itself. If reduction of the solid phase of the waste is necessary, exposure of the waste to the atmosphere should be avoided to the extent possible.

NOTE: Sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended.

When the surface area or particle-size has been appropriately altered, proceed to Step 7.3.7.

7.3.7 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge samples prior to filtration.

7.3.8 Quantitatively transfer the entire sample (liquid and solid phases) quickly to the ZHE. Secure the filter and support screens into the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extraction collection device to the top plate.

Note: If sample material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the ZHE, determine the weight of this residue and subtract it from the sample weight determined in Step 7.3.4 to determine the weight of the waste sample that will be filtered.

Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10 psig (or more if necessary) to force all headspace slowly out of the ZHE device into a hood. At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4°C reduces the

amount of expressed liquid over what would be expressed at room temperature, then allow the sample to warm up to room temperature in the device before filtering. If the waste is 100 % solid (see Step 7.1.1), slowly increase the pressure to a maximum of 50 psig to force most of the headspace out of the device and proceed to Step 7.3.12.

7.3.9 Attach the evacuated pre-weighed filtrate collection container to the liquid inlet/outlet valve and open the valve. Begin applying gentle pressure of 1-10 psig to force the liquid phase of the sample into the filtrate collection container. If no additional liquid has passed through the filter in any 2-minute interval, slowly increase the pressure in 10-psig increments to a maximum of 50 psig. After each incremental increase of 10 psig, if no additional liquid has passed through the filter in any 2-minute interval, proceed to the next 10-psig increment. When liquid flow has ceased such that continued pressure filtration at 50 psig does not result in any additional filtrate within a 2-minute period, stop the filtration. Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.3.10 The material in the ZHE is defined as the solid phase of the sample and the filtrate is defined as the liquid phase.

NOTE: Some samples, such as oily wastes and some paint wastes, will obviously contain some material which appears to be a liquid. Even after applying pressure filtration, this material will not filter. If this is the case, the material within the filtration device is defined as a solid, and is carried through the 1312 extraction as a solid.

If the original waste contained <0.5 % dry solids (see Step 7.1.2), this filtrate is defined as the 1312 extract and is analyzed directly. Proceed to Step 7.3.15.

7.3.11 The liquid phase may now be either analyzed immediately (see Steps 7.3.13 through 7.3.15) or stored at 4°C under minimal headspace conditions until time of analysis. Determine the weight of extraction fluid #3 to add to the ZHE as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \%\ \text{solids (Step 7.1.1)} \times \text{weight of waste filtered (Step 7.3.4 or 7.3.8)}}{100}$$

7.3.12 The following steps detail how to add the appropriate amount of extraction fluid to the solid material within the ZHE and agitation of the ZHE vessel. Extraction fluid #3 is used in all cases (see Step 5.4.3).

7.3.12.1 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid inlet/outlet valve. The line used shall contain fresh extraction fluid and should be preflushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device.

7.3.12.2 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device in an end-over-end fashion 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psig (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psig and check all ZHE fittings to ensure that they are closed.

7.3.12.3 Place the ZHE in the rotary extractor apparatus (if it is not already there) and rotate at 30 $\pm$ 2 rpm for 18 $\pm$ 2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23 $\pm$ 2°C during agitation.

7.3.13 Following the 18 $\pm$ 2 hour agitation period, check the pressure behind the ZHE piston by quickly opening and closing the gas inlet/outlet valve and noting the escape of gas. If the pressure has not been maintained (i.e., no gas release observed), the ZHE is leaking. Check the ZHE for leaking as specified in Step 4.2.1, and perform the extraction again with a new sample of waste. If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases. If the waste contained an initial liquid phase, the liquid may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combining would create multiple phases, or there is not enough volume left within the filtrate collection container. Filter through the glass fiber filter, using the ZHE device as discussed in Step 7.3.9. All extracts shall be filtered and collected if the TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase (see Steps 4.6 and 7.3.1).

NOTE: An in-line glass fiber filter may be used to filter the material within the ZHE if it is suspected that the glass fiber filter has been ruptured

7.3.14 If the original sample contained no initial liquid phase, the filtered liquid material obtained from Step 7.3.13 is defined as the 1312 extract. If the sample contained an initial liquid phase, the filtered liquid material obtained from Step 7.3.13 and the initial liquid phase (Step 7.3.9) are collectively defined as the 1312 extract.

7.3.15 Following collection of the 1312 extract, immediately prepare the extract for analysis and store with minimal headspace at 4°C until analyzed. Analyze the 1312 extract according to the appropriate analytical methods. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume- weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)\,(C_1) + (V_2)\,(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phases (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.3.16 Compare the analyte concentrations in the 1312 extract with the levels identified in the appropriate regulations. Refer to Step 8.0 for quality assurance requirements.

8.0 QUALITY CONTROL

8.1 A minimum of one blank (using the same extraction fluid as used for the samples) for every 20 extractions that have been conducted in an extraction vessel. Refer to Chapter One for additional quality control protocols.

8.2 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.) unless the result exceeds the regulatory level and the data is being used solely to demonstrate that the waste property exceeds the regulatory level. A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

8.2.1 Matrix spikes are to be added after filtration of the 1312 extract and before preservation. Matrix spikes should not be added prior to 1312 extraction of the sample.

8.2.2 In most cases, matrix spike levels should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the

spike concentration may be as low as one half of the analyte concentration, but may not be less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of 1312 extract as that which was analyzed for the unspiked sample.

8.2.3 The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist. Use of other internal calibration methods, modification of the analytical methods, or use of alternate analytical methods may be needed to accurately measure the analyte concentration in the 1312 extract when the recovery of the matrix spike is below the expected analytical method performance.

8.2.4 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%\ \text{Recovery}) = 100\ (X_s - X_u) / K$$

where:

X_s = measured value for the spiked sample
X_u = measured value for the unspiked sample, and
K = known value of the spike in the sample.

8.3 All quality control measures described in the appropriate analytical methods shall be followed.

8.4 The use of internal calibration quantitation methods shall be employed for a metallic contaminant if: (1) Recovery of the contaminant from the 1312 extract is not at least 50% and the concentration does not exceed the appropriate regulatory level, and (2) The concentration of the contaminant measured in the extract is within 20% of the appropriate regulatory level.

8.4.1. The method of standard additions shall be employed as the internal calibration quantitation method for each metallic contaminant.

8.4.2 The method of standard additions requires preparing calibration standards in the sample matrix rather than reagent water or blank solution. It requires taking four identical aliquots of the solution and adding known amounts of standard to three of these aliquots. The forth aliquot is the unknown. Preferably, the first addition should be prepared so that the resulting concentration is approximately 50% of the expected concentration of the sample. The second and third additions should be prepared so that the concentrations are approximately 100% and 150% of the expected concentration of the sample. All four aliquots are maintained at the same final volume by adding reagent water or a blank solution, and may need dilution adjustment to maintain the signals in the linear range of the instrument technique. All four aliquots are analyzed.

8.4.3 Prepare a plot, or subject data to linear regression, of instrument signals or external-calibration-derived concentrations as the dependant variable (y-axis) versus concentrations of the additions of standards as the independent variable (x-axis). Solve for the intercept

of the abscissa (the independent variable, x-axis) which is the concentration in the unknown.

8.4.4 Alternately, subtract the instrumental signal or external-calibration-derived concentration of the unknown (unspiked) sample from the instrumental signals or external-calibration-derived concentrations of the standard additions. Plot or subject to linear regression of the corrected instrument signals or external-calibration-derived concentrations as the dependant variable versus the independent variable. Derive concentrations for the unknowns using the internal calibration curve as if it were an external calibration curve.

8.5 Samples must undergo 1312 extraction within the following time periods:

SAMPLE MAXIMUM HOLDING TIMES (days)

	From: Field Collection To: 1312 extraction	From: 1312 extraction To: Preparative extraction	From: Preparative extraction To: Determinative analysis	Total Elapsed Time
Volatiles	14	NA	14	28
Semi-volatiles	14	7	40	61
Mercury	28	NA	28	56
Metals, except mercury	180	NA	180	360
NA = Not Applicable				

If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding the holding time is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory level.

9.0 METHOD PERFORMANCE

9.1 Precision results for semi-volatiles and metals: An eastern soil with high organic content and a western soil with low organic content were used for the semi-volatile and metal leaching experiments. Both types of soil were analyzed prior to contaminant spiking. The results are shown in Table 6. The concentration of contaminants leached from the soils were reproducible, as shown

by the moderate relative standard deviations (RSDs) of the recoveries (averaging 29% for the compounds and elements analyzed).

9.2 Precision results for volatiles: Four different soils were spiked and tested for the extraction of volatiles. Soils One and Two were from western and eastern Superfund sites. Soils Three and Four were mixtures of a western soil with low organic content and two different municipal sludges. The results are shown in Table 7. Extract concentrations of volatile organics from the eastern soil were lower than from the western soil. Replicate leachings of Soils Three and Four showed lower precision than the leachates from the Superfund soils.

MULTIPLE EXTRACTION PROCEDURE

1.0 SCOPE AND APPLICATION

The Multiple Extraction Procedure (MEP) described in this method is designed to simulate the leaching that a waste will undergo from repetitive precipitation of acid rain on an improperly designed sanitary landfill. The repetitive extractions reveal the highest concentration of each constituent that is likely to leach in a natural environment. Method 1320 is applicable to liquid, solid, and multiphase samples.

2.0 SUMMARY OF METHOD

Waste samples are extracted according to the Extraction Procedure Toxicity Test (Method 1310, Chapter 8) and analyzed for the constituents of concern listed in Chapter 7, Table 7-1: Maximum Concentration of Contaminants for Characteristic of EP Toxicity, using the 7000 and 8000 series methods. Then the solid portions of the samples that remain after application of Method 1310 are re-extracted nine times using synthetic acid rain extraction fluid. If the concentration of any constituent of concern increases from the 7th or 8th extraction to the 9th extraction, the procedure is repeated until these concentrations decrease.

3.0 INTERFERENCES

Potential interferences that may be encountered during analysis are discussed in the appropriate analytical methods.

4.0 APPARATUS AND MATERIALS

4.1 Refer to Method 1310.

5.0 REAGENTS

5.1 Refer to Method 1310.

5.2 Sulfuric acid:nitric acid, 60/40 weight percent mixture: Cautiously mix 60 g of concentrated sulfuric acid with 40 g of concentrated nitric acid.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Refer to Method 1310.

7.0 PROCEDURE

7.1 Run the Extraction Procedure (EP) test in Method 1310.

7.2 Analyze the extract for the constituents of interest.

7.3 Prepare a synthetic acid rain extraction fluid by adding the 60/40 weight percent sulfuric acid and nitric acid to distilled deionized water until the pH is 3.0 $\pm$ 0.2.

7.4 Take the solid phase of the sample remaining after the Separation Procedure of the Extraction Procedure and weigh it. Measure an aliquot of synthetic acid rain extraction fluid equal to 20 times the weight of the solid sample. Do not allow the solid sample to dry before weighing.

7.5 Combine the solid phase sample and acid rain fluid in the same extractor as used in the EP and begin agitation. Record the pH within 5-10 min after agitation has been started.

7.6 Agitate the mixture for 24 hr, maintaining the temperature at 20-40°C (68-104°F). Record the pH at the end of the 24-hr extraction period.

7.7 Repeat the Separation Procedure as described in Method 1310.

7.8 Analyze the extract for the constituents of concern.

7.9 Repeat steps 7.4-7.8 eight additional times.

7.10 If, after completing the ninth synthetic rain extraction, the concentration of any of the constituents of concern is increasing over that found in the 7th and 8th extractions, then continue extracting with synthetic acid rain until the concentration in the extract ceases to increase.

7.11 Report the initial and final pH of each extraction and the concentration of each listed constituent of concern in each extract.

8.0 QUALITY CONTROL

8.1 All quality control data should be maintained and available for easy reference or inspection.

8.2 Employ a minimum of one blank per sample batch to determine if contamination or any memory effects are occurring.

8.3 All quality control measures suggested in the referenced analytical methods should be followed.

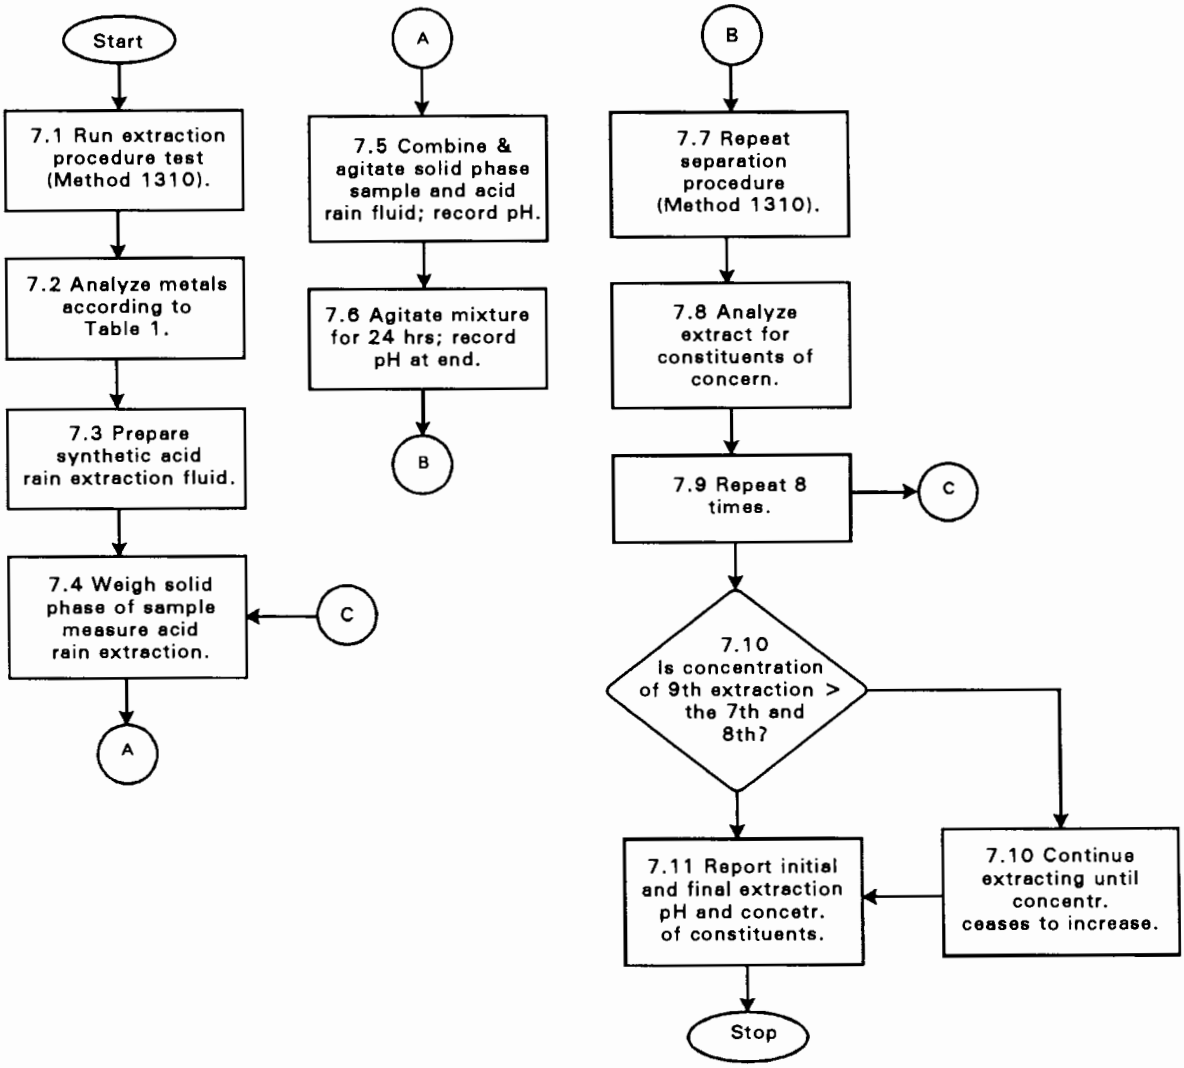
9.0 METHOD PERFORMANCE

9.1 No data provided.

10.0 REFERENCES

10.1 None required.

METHOD 1320
MULTIPLE EXTRACTION PROCEDURE



METHOD 1330A

EXTRACTION PROCEDURE FOR OILY WASTES

1.0 SCOPE AND APPLICATION

1.1 Method 1330 is used to determine the mobile metal concentration (MMC) in oily wastes.

1.2 Method 1330 is applicable to API separator sludges, rag oils, slop oil emulsions, and other oil wastes derived from petroleum refining.

2.0 SUMMARY OF METHOD

2.1 The sample is separated into solid and liquid components by filtration.

2.2 The solid phase is placed in a Soxhlet extractor, charged with tetrahydrofuran, and extracted. The THF is removed, the extractor is then charged with toluene, and the sample is reextracted.

2.3 The EP method (Method 1310) is run on the dry solid residue.

2.4 The original liquid, combined extracts, and EP leachate are analyzed for the EP metals.

3.0 INTERFERENCES

3.1 Matrix interferences will be coextracted from the sample. The extent of these interferences will vary considerably from waste to waste, depending on the nature and diversity of the particular refinery waste being analyzed.

4.0 APPARATUS AND MATERIALS

4.1 Soxhlet extraction apparatus.

4.2 Vacuum pump or other source of vacuum.

4.3 Buchner funnel 12.

4.4 Electric heating mantle.

4.5 Paper extraction thimble.

4.6 Filter paper.

4.7 Muslin cloth disks.

4.8 Evaporative flask - 250-mL.

4.9 Balance - Analytical, capable of weighing to $\pm$ 0.5 mg.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Tetrahydrofuran, C_4H_8O.

5.4 Toluene, $C_6H_5CH_3$.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Samples must be collected in glass containers having a total volume of at least 150 mL. No solid material should interfere with sealing the sample container.

6.2 Sampling devices should be wiped clean with paper towels or absorbent cloth, rinsed with a small amount of hexane followed by acetone rinse, and dried between samples. Alternatively, samples can be taken with disposable sampling devices in beakers.

7.0 PROCEDURE

7.1 Separate the sample (minimum 100 g) into its solid and liquid components. The liquid component is defined as that portion of the sample which passes through a 0.45 µm filter media under a pressure differential of 75 psi.

7.2 Determine the quantity of liquid (mL) and the concentration of the toxicants of concern in the liquid phase (mg/L).

7.3 Place the solid phase into a Soxhlet extractor, charge the concentration flask with 300 mL tetrahydrofuran, and extract for 3 hours.

7.4 Remove the flask containing tetrahydrofuran and replace it with one containing 300 mL toluene.

7.5 Extract the solid a second time, for 3 hours, with the toluene.

7.6 Combine the tetrahydrofuran and toluene extracts.

7.7 Analyze the combined extracts for the toxicants of concern.

7.8 Determine the quantity of liquid (mL) and the concentration of the toxicants of concern in the combined extracts (mg/L).

7.9 Take the solid material remaining in the Soxhlet thimble and dry it at 100°C for 30 minutes.

7.10 Run the EP (Method 1310) on the dried solid.

7.11 Calculate the mobile metal concentration (MMC) in mg/L using the following formula:

$$MMC = 1{,}000 \times \frac{(Q_1 + Q_2 + Q_3)}{(L_1 + L_2 + L_3)}$$

where:

Q_1 = Mass of toxicant in initial liquid phase of sample (amount of liquid x concentration of toxicant) (mg).

Q_2 = Mass of toxicant in combined organic extracts of sample (amount of liquid x concentration of toxicant) (mg).

Q_3 = Mass of toxicant in EP extract of solid (amount of extract x concentration of toxicant) (mg).

L_1 = Volume of initial liquid (mL).

L_2 = Volume of liquid in THF and toluene extract (Step 7.8) (mL).

L_3 = Volume of liquid in EP (mL) = 20 x [weight of dried solid from Step 7.9 (g)].

8.0 QUALITY CONTROL

8.1 Any reagent blanks or replicates samples should be subjected to exactly the same analytical procedures as those used on actual samples.

8.2 Refer to Chapter One for specific quality control procedures.

9.0 METHOD PERFORMANCE

9.1 No data provided.

ACID DIGESTION OF WATERS FOR TOTAL RECOVERABLE OR DISSOLVED METALS FOR ANALYSIS BY FLAA OR ICP SPECTROSCOPY

1.0 SCOPE AND APPLICATION

1.1 Method 3005 is an acid digestion procedure used to prepare surface and ground water samples for analysis by flame atomic absorption spectroscopy (FLAA) or by inductively coupled argon plasma spectroscopy (ICP). Samples prepared by Method 3005 may be analyzed by AAS or ICP for the following metals:

Aluminum	Magnesium
Antimony**	Manganese
Arsenic*	Molybdenum
Barium	Nickel
Beryllium	Potassium
Cadmium	Selenium*
Calcium	Silver
Chromium	Sodium
Cobalt	Thallium
Copper	Vanadium
Iron	Zinc
Lead	

* ICP only
**May be analyzed by ICP, FLAA, or GFAA

1.2 When analyzing for total dissolved metals filter the sample, at the time of collection, prior to acidification with nitric acid.

2.0 SUMMARY OF METHOD

2.1 Total recoverable metals - The entire sample is acidified at the time of collection with nitric acid. At the time of analysis the sample is heated with acid and substantially reduced in volume. The digestate is filtered and diluted to volume, and is then ready for analysis.

2.2 Dissolved metals - The sample is filtered through a 0.45-µm filter at the time of collection and the liquid phase is then acidified at the time of collection with nitric acid. Samples for dissolved metals do not need to be digested as long as the acid concentrations have been adjusted to the same concentration as in the standards.

3.0 INTERFERENCES

3.1 The analyst should be cautioned that this digestion procedure may not be sufficiently vigorous to destroy some metal complexes.

Precipitation will cause a lowering of the silver concentration and therefore an inaccurate analysis.

4.0 APPARATUS AND MATERIALS

4.1 Griffin beakers of assorted sizes or equivalent.

4.2 Watch glasses or equivalent.

4.3 Qualitative filter paper and filter funnels.

4.4 Graduated cylinder or equivalent.

4.5 Electric hot plate or equivalent - adjustable and capable of maintaining a temperature of 90-95°C.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. Reagent water shall be interference free. All references to water in the method refer to reagent water unless otherwise specified. Refer to Chapter One for a definition of reagent water.

5.3 Nitric acid (concentrated), HNO_3. Acid should be analyzed to determine level of impurities. If method blank is < MDL, then acid can be used.

5.4 Hydrochloric acid (concentrated), HCl. Acid should be analyzed to determine level of impurities. If method blank is < MDL, then acid can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be prewashed with detergents, acids, and water. Both plastic and glass containers are suitable.

6.3 Sampling

6.3.1 Total recoverable metals - All samples must be acidified at the time of collection with HNO_3 (5 mL/L).

6.3.2 Dissolved metals - All samples must be filtered through a 0.45-µm filter and then acidified at the time of collection with HNO_3 (5 mL/L).

7.0 PROCEDURE

7.1 Transfer a 100-mL aliquot of well-mixed sample to a beaker.

7.2 For metals that are to be analyzed, add 2 mL of concentrated HNO_3 and 5 mL of concentrated HCl. The sample is covered with a ribbed watch glass or other suitable covers and heated on a steam bath, hot plate or other heating source at 90 to 95°C until the volume has been reduced to 15-20 mL.

CAUTION: Do not boil. Antimony is easily lost by volatilization from hydrochloric acid media.

7.3 Remove the beaker and allow to cool. Wash down the beaker walls and watch glass with water and, when necessary, filter or centrifuge the sample to remove silicates and other insoluble material that could clog the nebulizer. Filtration should be done only if there is concern that insoluble materials may clog the nebulizer; this additional step is liable to cause sample contamination unless the filter and filtering apparatus are thoroughly cleaned and prerinsed with dilute HNO_3.

7.4 Adjust the final volume to 100 mL with reagent water.

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One should be followed.

8.2 For each analytical batch of samples processed, blanks should be carried throughout the entire sample preparation and analytical process. These blanks will be useful in determining if samples are being contaminated. Refer to Chapter One for the proper protocol when analyzing blanks.

8.3 Replicate samples should be processed on a routine basis. A replicate sample is a sample brought through the whole sample preparation and analytical process. Replicate samples will be used to determine precision. The sample load will dictate the frequency, but 5% is recommended. Refer to Chapter One for the proper protocol when analyzing replicates.

8.4 Spiked samples or standard reference materials should be employed to determine accuracy. A spiked sample should be included with each batch. Refer to Chapter One for the proper protocol when analyzing spikes.

9.0 METHOD PERFORMANCE

9.1 No data provided.

ACID DIGESTION OF AQUEOUS SAMPLES AND EXTRACTS FOR TOTAL METALS FOR ANALYSIS BY FLAA OR ICP SPECTROSCOPY

1.0 SCOPE AND APPLICATION

1.1 This digestion procedure is used for the preparation of aqueous samples, EP and mobility-procedure extracts, and wastes that contain suspended solids for analysis, by flame atomic absorption spectroscopy (FLAA) or inductively coupled argon plasma spectroscopy (ICP). The procedure is used to determine total metals.

1.2 Samples prepared by Method 3010 may be analyzed by FLAA or ICP for the following:

Aluminum	Magnesium
*Arsenic	Manganese
Barium	Molybdenum
Beryllium	Nickel
Cadmium	Potassium

Iron	Zinc
Lead	

* Analysis by ICP

NOTE: See Method 7760 for the digestion and FLAA analysis of Silver.

1.3 This digestion procedure is not suitable for samples which will be analyzed by graphite furnace atomic absorption spectroscopy because hydrochloric acid can cause interferences during furnace atomization. Consult Method 3020A for samples requiring graphite furnace analysis.

2.0 SUMMARY OF METHOD

2.1 A mixture of nitric acid and the material to be analyzed is refluxed in a covered Griffin beaker. This step is repeated with additional portions of nitric acid until the digestate is light in color or until its color has stabilized. After the digestate has been brought to a low volume, it is refluxed with hydrochloric acid and brought up to volume. If sample should go to dryness, it must be discarded and the sample reprepared.

3.0 INTERFERENCES

3.1 Interferences are discussed in the referring analytical method.

4.0 APPARATUS AND MATERIALS

4.1 Griffin beakers - 150-mL or equivalent.

4.2 Watch glasses - Ribbed and plain or equivalent.

4.3 Qualitative filter paper or centrifugation equipment.

4.4 Graduated cylinder or equivalent - 100mL.

4.5 Funnel or equivalent.

4.6 Hot plate or equivalent heating source - adjustable and capable of maintaining a temperature of 90-95°C.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. Reagent water will be interference free. All references to water in the method refer to reagent water unless otherwise specified. Refer to Chapter One for a definition of reagent water.

5.3 Nitric acid (concentrated), HNO_3. Acid should be analyzed to determine levels of impurities. If method blank is < MDL, the acid can be used.

5.4 Hydrochloric acid (1:1), HCl. Prepared from water and hydrochloric acid. Hydrochloric acid should be analyzed to determine level of impurities. If method blank is < MDL, the acid can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be prewashed with detergents, acids, and water. Plastic and glass containers are both suitable. See Chapter Three, Step 3.1.3, for further information.

6.3 Aqueous wastewaters must be acidified to a pH of < 2 with HNO_3.

7.0 PROCEDURE

7.1 Transfer a 100-mL representative aliquot of the well-mixed sample to a 150-mL Griffin beaker and add 3 mL of concentrated HNO_3. Cover the beaker with

a ribbed watch glass or equivalent. Place the beaker on a hot plate or equivalent heating source and cautiously evaporate to a low volume (5 mL), making certain that the sample does not boil and that no portion of the bottom of the beaker is allowed to go dry. Cool the beaker and add another 3-mL portion of concentrated HNO_3. Cover the beaker with a nonribbed watch glass and return to the hot plate. Increase the temperature of the hot plate so that a gentle reflux action occurs.

NOTE: If a sample is allowed to go to dryness, low recoveries will result. Should this occur, discard the sample and reprepare.

7.2 Continue heating, adding additional acid as necessary, until the digestion is complete (generally indicated when the digestate is light in color or does not change in appearance with continued refluxing). Again, uncover the beaker or use a ribbed watch glass, and evaporate to a low volume (3 mL), not allowing any portion of the bottom of the beaker to go dry. Cool the beaker. Add a small quantity of 1:1 HCl (10 mL/100 mL of final solution), cover the beaker, and reflux for an additional 15 minutes to dissolve any precipitate or residue resulting from evaporation.

7.3 Wash down the beaker walls and watch glass with water and, when necessary, filter or centrifuge the sample to remove silicates and other insoluble material that could clog the nebulizer. Filtration should be done only if there is concern that insoluble materials may clog the nebulizer. This additional step can cause sample contamination unless the filter and filtering apparatus are thoroughly cleaned. Rinse the filter and filter apparatus with dilute nitric acid and discard the rinsate. Filter the sample and adjust the final volume to 100 mL with reagent water and the final acid concentration to 10%. The sample is now ready for analysis.

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One should be followed.

8.2 For each analytical batch of samples processed, blanks should be carried throughout the entire sample-preparation and analytical process. These blanks will be useful in determining if samples are being contaminated. Refer to Chapter One for the proper protocol when analyzing blanks.

8.3 Replicate samples should be processed on a routine basis. A replicate sample is a sample brought through the whole sample preparation and analytical process. A replicate sample should be processed with each analytical batch or every 20 samples, whichever is greater. Refer to Chapter One for the proper protocol when analyzing replicates.

8.4 Spiked samples or standard reference materials should be employed to determine accuracy. A spiked sample should be included with each batch of samples processed and whenever a new sample matrix is being analyzed. Refer to Chapter One for the proper protocol when analyzing spikes.

8.5 The method of standard addition shall be used for the analysis of all EP extracts and delisting petitions (see Method 7000, Step 8.7). Although not

required, use of the method of standard addition is recommended for any sample that is suspected of having an interference.

9.0 METHOD PERFORMANCE

9.1 No data provided.

METHOD 3015

MICROWAVE ASSISTED ACID DIGESTION OF AQUEOUS SAMPLES AND EXTRACTS

1.0 SCOPE AND APPLICATION

1.1 This digestion procedure is used for the preparation of aqueous samples, mobility-procedure extracts, and wastes that contain suspended solids for analysis, by flame atomic absorption spectroscopy (FLAA), graphite furnace absorption spectroscopy (GFAA), inductively coupled argon plasma spectroscopy (ICP), or inductively coupled argon plasma mass spectrometry (ICP-MS). The procedure is a hot acid leach for determining available metals. Due to the rapid advances in microwave technology, consult your manufacturer's recommended instructions for guidance on their microwave digestion system and refer to the SW-846 "DISCLAIMER" when conducting analyses using Method 3015.

1.2 Samples prepared by Method 3015 using nitric acid digestion may be analyzed by FLAA, GFAA, ICP-AES, or ICP-MS for the following:

Aluminum	Lead
Antimony	Magnesium
Arsenic*	Manganese
Barium	Molybdenum
Beryllium	Nickel
Cadmium	Potassium
Calcium	Selenium*
Chromium	Silver
Cobalt	Sodium
Copper	Thallium
Iron	Vanadium
	Zinc

*Cannot be analyzed by FLAA

2.0 SUMMARY OF METHOD

2.1 A representative 45 mL aqueous sample is digested in 5 mL of concentrated nitric acid in a fluorocarbon (PFA or TFM) digestion vessel for 20 minutes using microwave heating. After the digestion process, the sample is cooled, and then filtered, centrifuged, or allowed to settle in a clean sample bottle prior to analysis.

3.0 INTERFERENCES

3.1 Many samples that contain organics, such as TCLP extracts, will result in higher vessel pressures which have the potential to cause venting of the vessels. Venting can result in either loss of analytes and/or sample, which

must be avoided. A smaller sample size can be used but the final water volume prior to nitric acid addition must remain at 45 mL. This is required to retain the heat characteristics of the calibration procedure. Limits of quantitation will change with sample quantity (dilution) as with instrumentation."

4.0 APPARATUS AND MATERIALS

4.1 Microwave apparatus requirements

4.1.1 The microwave unit provides programmable power with a minimum of 574 W, which can be programmed to within ± 10 W of the required power. Typical units provide a nominal 600 W to 1200 W of power. Temperature monitoring and control of the microwave unit are desirable.

4.1.2 The microwave unit cavity is corrosion resistant and well ventilated.

4.1.3 All electronics are protected against corrosion for safe operation.

4.1.4 The system requires fluorocarbon (PFA or TFM) digestion vessels (120 mL capacity) capable of withstanding pressures up to 7.5 ± 0.7 atm (110 ± 10 psig) and capable of controlled pressure relief at pressures exceeding 7.5 ± 0.7 atm (110 ± 10 psig).

4.1.5 A rotating turntable is employed to insure homogeneous distribution of microwave radiation within the unit. The speed of the turntable should be a minimum of 3 rpm.

CAUTION: Those laboratories now using or contemplating the use of kitchen type microwave ovens for this method should be aware of several significant safety issues. First, when an acid such as nitric is used to assist sample digestion in microwave units in open vessels, or sealed vessels equipped with venting features, there is the potential for the acid gases released to corrode the safety devices that prevent the microwave magnetron from shutting off when the door is opened. This can result in operator exposure to microwave energy. Use of a unit with corrosion resistant safety devices prevents this from occurring.

CAUTION: The second safety concern relates to the use of sealed containers without pressure relief valves in the unit. Temperature is the important variable controlling the reaction. Pressure is needed to attain elevated temperatures but must be safely contained. However, many digestion vessels constructed from certain fluorocarbons may crack, burst, or explode in the oven under certain pressures. Only unlined fluorocarbon (PFA or TFM) containers with pressure relief mechanisms or containers with fluorocarbon (PFA or TFM) liners and pressure relief mechanisms are considered acceptable at present.

Users are therefore advised not to use kitchen type microwave ovens or to use sealed containers without pressure relief valves for microwave acid digestions by this method. Use of laboratory grade microwave equipment is required to prevent safety hazards. For further information consult reference 1.

CAUTION: In addition, there are many safety and operational recommendations specific to the model and manufacturer of the microwave equipment used in individual laboratories. These specific suggestions are beyond the scope of this method and require the analyst to consult the specific equipment manual, manufacturer and literature for proper and safe operation of the microwave equipment and vessels.

4.2 Volumetric graduated cylinder, 50 or 100 mL capacity or equivalent.

4.3 Filter paper, qualitative or equivalent.

4.4 Analytical balance, 300 g capacity, minimum accuracy ± 0.01 g.

4.5 Filter funnel, glass or disposable polypropylene.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is questionable, analyze the reagent to determine the level of impurities. The reagent blank must be less than the MDL in order to be used.

5.2 Reagent Water. Reagent water shall be interference free. All references to water in the method refer to reagent water unless otherwise specified (Ref. 2).

5.3 Concentrated nitric acid, HNO_3. Acid should be analyzed to determine levels of impurities. If the method blank is less than the MDL, the acid can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be prewashed with detergents, acids, and water. Plastic containers are preferable. See Chapter Three, Step 3.1.3 of this manual, for further information.

6.3 Aqueous waste waters must be acidified to a pH of < 2 with HNO_3.

7.0 PROCEDURE

7.1 Calibration of Microwave Equipment

NOTE: If the microwave unit uses temperature feedback control capable of replicating the performance specifications of the method, then the calibration procedure may be omitted.

7.1.1 Measurement of the available power for heating is evaluated so that absolute power in watts may be transferred from one microwave unit to another. For cavity type microwave equipment, this is accomplished by measuring the temperature rise in 1 kg of water exposed to microwave radiation for a fixed period of time. The analyst can relate power in watts to the partial power setting of the unit. The calibration format required for laboratory microwave units depends on the type of electronic system used by the manufacturer to provide partial microwave power. Few units have an accurate and precise linear relationship between percent power settings and absorbed power. Where linear circuits have been utilized, the calibration curve can be determined by a three-point calibration method (7.1.3), otherwise, the analyst must use the multiple point calibration method (7.1.2).

7.1.2 The multiple point calibration involves the measurement of absorbed power over a large range of power settings. Typically, for a 600 W unit, the following power settings are measured; 100,99,98,97, 95,90,80,70,60,50, and 40% using the procedure described in section 7.1.4. This data is clustered about the customary working power ranges. Nonlinearity has been commonly encountered at the upper end of the calibration. If the unit's electronics are known to have nonlinear deviations in any region of proportional power control, it will be necessary to make a set of measurements that bracket the power to be used. The final calibration point should be at the partial power setting that will be used in the test. This setting should be checked periodically to evaluate the integrity of the calibration. If a significant change is detected (±10 W), then the entire calibration should be reevaluated.

7.1.3 The three-point calibration involves the measurement of absorbed power at three different power settings. Measure the power at 100% and 50% using the procedure described in section 7.1.4, and calculate the power setting corresponding to the required power in watts specified in the procedure from the (2-point) line. Measure the absorbed power at that partial power setting. If the measured absorbed power does not correspond to the specified power within ±10 W, use the multiple point calibration in 7.1.2. This point should also be used to periodically verify the integrity of the calibration.

7.1.4 Equilibrate a large volume of water to room temperature (23 ± 2 °C). One kg of reagent water is weighed (1,000.0 g $\pm$ 0.1 g) into a fluorocarbon (PFA or TFM) beaker or a beaker made of some other

material that does not significantly absorb microwave energy (glass absorbs microwave energy and is not recommended). The initial temperature of the water should be 23 ± 2 °C measured to ± 0.05 °C. The covered beaker is circulated continuously (in the normal sample path) through the microwave field for 2 minutes at the desired partial power setting with the unit's exhaust fan on maximum (as it will be during normal operation). The beaker is removed and the water vigorously stirred. Use a magnetic stirring bar inserted immediately after microwave irradiation and record the maximum temperature within the first 30 seconds to ± 0.05 °C. Use a new sample for each additional measurement. If the water is reused both the water and the beaker must have returned to 23 ± 2 °C. Three measurements at each power setting should be made.

The absorbed power is determined by the following relationship

$$P = \frac{(K)\ (C_p)\ (m)\ (\Delta T)}{t} \qquad \text{Eq. 1}$$

Where:

P = the apparent power absorbed by the sample in watts (W). ($W = joule \cdot sec^{-1}$)

K = the conversion factor for thermochemical calories·sec^{-1} to watts (=4.184)

C_p = the heat capacity, thermal capacity, or specific heat ($cal \cdot g^{-1} \cdot °C^{-1}$), of water

m = the mass of the water sample in grams (g)

ΔT = the final temperature minus the initial temperature (°C)

t = the time in seconds (s)

Using the experimental conditions of 2 minutes and 1 kg of distilled water (heat capacity at 25 °C is 0.9997 $cal \cdot g^{-1} \cdot °C^{-1}$) the calibration equation simplifies to:

$$P = (\Delta T)\ (34.86)$$

NOTE: Stable line voltage is necessary for accurate and reproducible calibration and operation. The line voltage should be within manufacturer's specification, and during measurement and operation not vary by more than ±2 V. A constant power supply may be necessary for microwave use if the source of the line voltage is unstable.

Electronic components in most microwave units are matched to the units' function and output. When any part of the high voltage circuit, power source, or control components in the unit have been serviced or replaced, it will be necessary to recheck the units' calibration power. If the power output has changed significantly (±10 W), then the entire calibration should be reevaluated.

7.2 All digestion vessels and volumetric ware must be carefully acid washed and rinsed with reagent water. When switching between high solids (concentrated) samples and low solids (low concentration) samples all digestion vessels should be cleaned by leaching with hot (1:1) hydrochloric acid (greater than 80°C, but less than boiling) for a minimum of two hours followed with hot (1:1) nitric acid (greater than 80°C, but less than boiling) for a minimum of two hours, rinsed with reagent water, and dried in a clean environment. This cleaning procedure should also be used whenever the prior use of the digestion vessels is unknown or cross contamination from vessels is suspected. Polymeric or glass volumetric ware and storage containers should be cleaned by leaching with more dilute acids (approximately 10% V/V) appropriate for the specific plastics used and then rinsed with reagent water and dried in a clean environment. In addition, to avoid precipitation of silver, ensure that all HCl has been rinsed from the vessels.

7.3 Sample Digestion

7.3.1 Weigh the fluorocarbon (PFA or TFM) digestion vessel, valve and cap assembly to 0.01 g prior to use.

7.3.2 A 45 mL aliquot of a well shaken sample is measured in a graduated cylinder. This aliquot is poured into the digestion vessel with the number of the vessel recorded on the preparation sheet.

7.3.3 A blank sample of reagent water is treated in the same manner along with spikes and duplicates.

7.3.4 Add 5 mL of concentrated nitric acid to each vessel that will be used. Check to make sure the pressure relief disks are in the caps with the smooth side toward the sample and start the caps a few turns on the vessels. Finish tightening the caps in the capping station which will tighten them to a uniform torque pressure of 12 ft-lbs. (16 N-m) or to the manufacturers recommended specifications. Weigh each capped vessel to the nearest 0.01 g.

CAUTION: Toxic nitrogen oxide fumes may be evolved, therefore all work must be performed in a properly operating ventilation system. The analyst should also be aware of the potential for a vigorous reaction. If a vigorous reaction occurs, allow to cool before capping the vessel.

7.3.5 Evenly distributed the vessels in the carousel according to the manufacturer's recommended specifications. Blanks are treated

as samples for the purpose of balancing the power input. When fewer than the recommended number of samples are digested, the remaining vessels should be filled with 45 mL of reagent water and 5 mL of nitric acid to achieve the full compliment of vessels. This provides an energy balance since the microwave power absorbed is proportional to the total mass in the cavity (Ref. 1).

7.3.6 Program the microwave unit according to the manufacturer's recommended specifications and, if used, connect the pressure vessels to the central overflow vessel with PFA-fluorocarbon tubes. The chosen sequence will bring the samples to 160°C ± 4°C in 10 minutes and will permit a slow rise to 165-170 °C during the second 10 minutes (Ref. 3). Start the turntable motor and be sure the vent fan is running on high and the turntable is turning. Start the microwave generator.

7.3.6.1 Newer microwave units are capable of higher power that permit digestion of a larger number of samples per batch. If the analyst wishes to digest more samples at a time, the analyst may use different power settings as long as they result in the same time and temperature conditions defined in 7.3.6. That is, any sequence of power that brings the samples to 160°C ± 4°C in 10 minutes and permits a slow rise to 165-170°C during the second 10 minutes (Ref. 2).

Issues of safety, structural integrity (both temperature and pressure limitations), heat loss, chemical compatibility, microwave absorption of vessel material, and energy transport will be considerations made in choosing alternative vessels. If all of the considerations are met and the appropriate power settings are provided to reproduce the reaction conditions defined in 7.3.6, then these alternative vessels may be used (Ref. 1,3)

7.3.7 At the end of the microwave program, allow the vessels to cool for at least 5 minutes in the unit before removal to avoid possible injury if a vessel vents immediately after microwave heating. The samples may be cooled outside the unit by removing the carousel and allowing the samples to cool on the bench or in a water bath. When the vessels have cooled to room temperature, weigh and record the weight of each vessel assembly. If the weight of the sample plus acid has decreased by more than 10% discard the sample.

7.3.8 Complete the preparation of the sample by carefully uncapping and venting each vessel in a fume hood. Transfer the sample to an acid-cleaned bottle. If the digested sample contains particulates which may clog nebulizers or interfere with injection of the sample into the instrument, the sample may be centrifuged, allowed to settle or filtered.

7.3.8.1 Centrifugation: Centrifugation at 2,000-3,000 rpm for 10 minutes is usually sufficient to clear the supernatant.

7.3.8.2 Settling: Allow the sample to stand until the supernatant is clear. Allowing a sample to stand overnight will usually accomplish this. If it does not, centrifuge or filter the sample.

7.3.8.3 Filtering: The filtering apparatus must be thoroughly cleaned and prerinsed with dilute (approximately 10% V/V) nitric acid. Filter the sample through qualitative filter paper into a second acid-cleaned cotainer.

7.3.9 The concentration values obtained from analysis must be corrected for the dilution factor from the acid addition. If the sample will be analyzed by ICP-MS additional dilution will generally be necessary. For example, the sample may be diluted by a factor of 20 with reagent water and the acid strength adjusted back to 10% prior to analysis. The dilutions used should be recorded and the measured concentrations adjusted accordingly (e.g., for a 45 mL sample and 5 mL of acid the correction factor is 1.11).

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One, of this Manual, should be followed.

8.2 For each analytical batch of samples processed, analytical reagent blanks (also field blanks if they were taken) should be carried throughout the entire sample preparation and analytical process. These blanks will be useful in determining if samples are being contaminated.

8.3 Duplicate samples should be processed on a routine basis. A duplicate sample is a real sample brought through the whole sample preparation and analytical process. A duplicate sample should be processed with each analytical batch or every 20 samples, whichever is the greater number.

8.4 Spiked samples or standard reference materials should be employed to determine accuracy. A spiked sample should be included with each group of samples processed and whenever a new sample matrix is being analyzed.

9.0 METHOD PERFORMANCE

9.1 Refer to Table 1 for a summary of performance data.

USEPA METHOD 3015A

MICROWAVE ASSISTED ACID DIGESTION OF AQUEOUS SAMPLES AND EXTRACTS

1.0 SCOPE AND APPLICATION

1.1 This microwave method is designed to perform extraction using microwave heating with nitric acid (HNO_3), or alternatively, nitric acid and hydrochloric acid (HCl). Since this method is not intended to accomplish total decomposition of the sample, the extracted analyte concentrations may not reflect the total content in the sample. This method is applicable to the microwave-assisted acid extraction/dissolution of available metals in aqueous samples, drinking water, mobility-procedure extracts, and wastes that contain suspended solids for the following elements:

Element		CASRN[a]
Aluminum	(Al)	7429-90-5*
Antimony	(Sb)	7440-36-0*
Arsenic	(As)	7440-38-2
Barium	(Ba)	7440-39-3*
Beryllium	(Be)	7440-41-7*
Boron	(B)	7440-42-8
Cadmium	(Cd)	7440-43-9
Calcium	(Ca)	7440-70-2
Chromium	(Cr)	7440-47-3*
Cobalt	(Co)	7440-48-4
Copper	(Cu)	7440-50-8
Iron	(Fe)	7439-89-6*
Lead	(Pb)	7439-92-1
Magnesium	(Mg)	7439-95-4*
Manganese	(Mn)	7439-96-5
Mercury	(Hg)	7439-97-6
Molybdenum	(Mo)	7439-98-7
Nickel	(Ni)	7440-02-0
Potassium	(K)	7440-09-7
Selenium	(Se)	7782-49-2
Silver	(Ag)	7440-22-4*
Sodium	(Na)	7440-23-5
Strontium	(Sr)	7440-24-6
Thallium	(Tl)	7440-28-0
Vanadium	(V)	7440-62-2*
Zinc	(Zn)	7440-66-6

[a]Chemical Abstract Service Registry Number

*Elements which typically require the addition of HCl for optimum recoveries. Other elements and matrices may be analyzed by this method if performance is demonstrated for the analyte of interest, in the matrices of interest, at the concentration levels of interest (see Sec. 9.0).

1.2 This method provides options for improving the performance for certain analytes, such as antimony, iron, aluminum, and silver by the addition of hydrochloric acid, when necessary. It is intended to provide a rapid multi-element acid extraction prior to analysis so that decisions can be made about materials and site clean-up levels, and as an estimate of metal toxicity. Digests produced by the method are suitable for analysis by inductively coupled plasma mass spectrometry (ICP-MS), inductively coupled plasma atomic emission spectrometry (ICP-AES), flame atomic absorption spectrophotometry (FLAA), and graphite furnace atomic absorption spectrophotometry (GFAA). However, the addition of HCl may limit the methods of detection, or increase the difficulties of detection with some techniques.

Due to the rapid advances in microwave technology, consult the manufacturer's recommended instructions for guidance on their microwave digestion system. This method is generic and may be implemented using a wide variety of laboratory microwave equipment.

2.0 SUMMARY OF METHOD

2.1 A representative 45 mL aqueous sample is extracted in 5 mL concentrated nitric acid or, optionally, 4 mL concentrated nitric acid and 1 mL concentrated hydrochloric acid, for 20 minutes using microwave heating with a suitable laboratory microwave unit. The temperature of the acid-sample mixture is brought to 170 ± 5 °C in 10 minutes, and maintained at 170 ± 5 °C for 10 minutes to accelerate the leaching process. The sample and acid(s) are placed in a fluorocarbon polymer (such as PFA or TFM) or quartz microwave vessel or vessel liner. The vessel is sealed and heated in the microwave unit. After cooling, the vessel contents are filtered, centrifuged, or allowed to settle and then diluted to volume and analyzed by the appropriate determinative method.

3.0 DEFINITIONS

Refer to Chapter One and Chapter Three for a listing of applicable definitions.

4.0 INTERFERENCES

4.1 Digestion of samples which contain organics will create high pressures due to the evolution of gaseous digestion products. This may cause venting of the vessels with potential loss of sample components and/or analytes. When warranted by the potential reactivity of the sample, a smaller sample size may be used, and the concentration for final calculations adjusted, but the final water volume prior to addition of acid(s) is recommended to be 45 mL. This is recommended in order to retain the heat characteristics of the calibration procedure if used. Variations of the method, due to very reactive materials, are specifically addressed in Section 11.3.3. Limits of quantitation will change with sample quantity (dilution) and with instrumentation.

4.2 Many samples can be dissolved by this method. However, when the sample contains suspended solids which are made up of refractory compounds, such as silicon dioxide, titanium dioxide, alumina, and other oxides, they will not be dissolved and in some cases may sequester target analyte elements. These bound elements are considered nonmobile in the environment and are excluded from most aqueous pollutant transport mechanisms.

5.0 SAFETY

5.1 The microwave unit cavity must be corrosion resistant and well ventilated. All electronics must be well protected against corrosion for safe operation.

CAUTION: *There are many safety and operational recommendations specific to the model and manufacturer of the microwave equipment used in individual laboratories. A listing of these specific suggestions is beyond the scope of this method. The analyst is advised to consult the*

equipment manual, the equipment manufacturer, and other appropriate literature for proper and safe operation of the microwave equipment and vessels. For further details and safety literature, references 1, 7 and 8 review methods and safety in microwave sample preparation.

5.2 The method requires microwave transparent and reagent resistant materials such as fluorocarbon polymers (examples are PFA and TFM) or quartz to contain acids and samples. For higher pressure capabilities, the vessel may be contained within layers of different microwave transparent materials for strength, durability, and safety. The internal volume of the vessel should be at least 100 mL, and the vessel must be capable of withstanding pressures of at least 30 atm (435 psi), and capable of controlled pressure relief. These specifications are to provide an appropriate, safe, and durable reaction vessel of which there are many adequate designs by many suppliers.

CAUTION: *The outer layers of vessels are frequently not as acid or reagent resistant as the liner material. In order to retain the specified performance and safety requirements, these outer layers must not be chemically degraded or physically damaged. Routine examination of the vessel materials is necessary to ensure their safe use.*

CAUTION: *Another safety concern relates to the use of sealed containers without pressure relief devices. Temperature is the important variable controlling the reaction. Pressure is needed to attain elevated temperatures, but must be safely contained. Some digestion vessels constructed from certain fluorocarbons may crack, burst, or explode in the unit under certain pressures. Only fluorocarbon (such as PFA, TFM, and others) or quartz containers with pressure relief mechanisms or containers with fluorocarbon or quartz liners and pressure relief mechanisms are considered acceptable.*

CAUTION: *An aqueous sample must contain no more than 1% (V/V or g/V) oxidizable organic material. Upon oxidation, organic material, whether liquid or solid, contributes to gaseous digestion products. Pressure build-up above the pressure limit will result in venting of the closed digestion vessel.*

CAUTION: *Laboratories should not use domestic (kitchen) type microwave ovens for this method because of significant safety issues. When acids such as nitric and hydrochloric are used to effect sample digestion in microwave units in open or sealed vessel(s), there is the potential for acid vapors released to corrode the safety devices that prevent the microwave magnetron from shutting off when the door is opened. This can result in operator exposure to microwave energy. Use of a system with isolated and corrosion resistant instrument components and safety devices prevents this from occurring.*

Users are advised not to use domestic (kitchen) type microwave ovens or sealed containers which are not equipped with controlled pressure relief mechanisms for microwave acid digestions by this method. Use of laboratory-grade microwave equipment is required to prevent safety hazards. For further details, consult references 1, 7, and 8.

6.0 EQUIPMENT AND SUPPLIES

6.1 Microwave apparatus requirements

6.1.1 The temperature performance requirements necessitate the microwave decomposition system to sense the temperature to within ± 2.5 °C and automatically adjust the microwave field output power within 2 seconds of sensing. Temperature sensors should be accurate to ± 2 °C (including the final reaction temperature of 170 ± 5 °C). Temperature feedback control provides the primary performance mechanism for the method. Due to the variability in sample matrix types and microwave digestion equipment (i.e., different vessel types and microwave oven designs), temperature feedback control is preferred for reproducible microwave heating. For further details, consult reference 7.

Alternatively, for a specific vessel type, specific set of reagent(s), and sample type, a calibration control mechanism can be developed similar to those described in previous microwave methods (See EPA Method 3051). Through calibration of the microwave power for a specific number and type of vessel, vessel load, and heat loss characteristics of a specific vessel series, the reaction temperature profile described in Section 11.3.5 can be reproduced (Reference 7). The calibration settings are specific for the number and type of vessel and microwave system being used, in addition to the specific reagent combination being used. Therefore, no specific calibration settings are provided in this method. These settings may be developed by using temperature monitoring equipment for each specific set of microwave equipment and vessel type. They may be used as previously described in EPA Methods 3052 and 3051. In this circumstance, the microwave system provides programmable power, which can be programmed to within ±12 W of the required power. Typical systems provide 600 W - 1200 W of power. Calibration control provides backward compatibility with older laboratory microwave systems which may not be equipped for temperature monitoring or feedback control and with lower cost microwave systems for some repetitive analyses. Older vessels with lower pressure capabilities may not be compatible (References 4 - 8).

6.1.2 The accuracy of the temperature measurement system should be periodically validated at an elevated temperature. This can be done using a container of silicon oil (a high temperature oil) and an external, calibrated temperature measurement system. The oil should be adequately stirred to ensure a homogeneous temperature, and both the microwave temperature sensor and the external temperature sensor placed into the oil. After heating the oil to a constant temperature of 170 ± 5°C, the temperature should be measured using both sensors. If the measured temperatures vary by more than 1 to 2°C, the microwave temperature measurement system should be calibrated. Consult the microwave manufacturer's instructions about the specific temperature sensor calibration procedure (see EPA Method 3052).

6.1.3 A rotating turntable is employed to ensure the homogeneous distribution of microwave radiation within the unit. The speed of the turntable should be a minimum of 3 rpm. Other types of equipment that are used to assist in achieving uniformity of the microwave field may also be appropriate.

6.2 Class A or appropriate mechanical pipette, volumetric flask, or graduated cylinder, 50 or 100 mL capacity or equivalent.

6.3 Filter paper, qualitative or equivalent.

6.4 Filter funnel, glass, polypropylene, or other appropriate material.

6.5 Analytical balance, of appropriate capacity and resolution, meeting data quality objectives.

7.0 REAGENTS

7.1 All acids should be sub-boiling distilled and/or high purity where possible to minimize blank levels due to metallic contamination. Other grades may be used, provided it is first ascertained that the reagent is of sufficient purity to permit its use without decreasing the accuracy of the determination. If the purity of a reagent is questionable, the reagent should be analyzed to determine the level of impurities. The reagent blank must be less than the MDL in order to be used.

7.1.1 Concentrated nitric acid (HNO_3). The acid should be analyzed to determine levels of impurity. If the method blank is less than the MDL, the acid can be used.

7.1.2 Concentrated hydrochloric acid (HCl). The acid should be analyzed to determine levels of impurity. If the method blank is less than the MDL, the acid can be used.

7.2 Reagent Water. Reagent water shall be interference free. All references to water in the method refer to reagent water unless otherwise specified. For further details, consult Reference 2.

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of SW-846. Refer to that chapter, as updated, for guidance.

8.2 All sample containers must be prewashed with acids, water, and metal-free detergents, if necessary, depending on the use history of the container (Reference 7). Plastic and glass containers are both suitable. For further information, see Chapter Three.

8.3 Aqueous wastewaters must be acidified to a pH < 2 with HNO_3.

9.0 QUALITY CONTROL

9.1 All quality control data must be maintained and available for reference or inspection for a period of three years. This method is restricted to use by, or under supervision of, experienced analysts.

9.2 Duplicate samples should be processed on a routine basis. A duplicate sample is a sample brought through the whole sample preparation and analysis process. A duplicate sample should be processed with each analytical batch or every 20 samples, whichever is the greater number. A duplicate sample should be prepared for each matrix type (i.e., wastewaters, extracts, etc.).

9.3 Spiked samples or standard reference materials should be included with each group of samples processed, or every 20 samples, whichever is the greater number. A spiked sample should also be included whenever a new sample matrix is being analyzed.

9.4 Periodically, the accuracy of the temperature measurement system used to control the microwave equipment should be validated per Section 6.1.2.

9.5 (Not necessary if using temperature feedback control.) Each day that samples are extracted, the microwave-power calibration should be verified by heating 1 kg of ASTM Type II water (at 22 ± 3 °C) in a covered, microwave-transparent vessel for 2 min at the setting for 490 W and measuring the water temperature after heating per Section 10.1.5. If the power calculated (per Section 12) differs from 490 W by more than ± 10 W, the microwave settings should be recalibrated per Section 10.0.

10.0 CALIBRATION AND STANDARDIZATION

10.1 Calibration of Microwave Equipment

NOTE: *If the microwave unit uses temperature feedback control to control the performance specifications of the method, then performing the calibration procedure is not necessary.*

10.1.1 Calibration is the normalization and reproduction of a microwave field strength to permit reagent and energy coupling in a predictable and reproducible manner. It balances reagent heating and heat loss from the vessels and is equipment dependent due to the heat retention and loss characteristics of the specific vessel. Available power is

evaluated to permit the microwave field output in watts to be transferred from one microwave system to another.

Use of calibration to control this reaction requires balancing output power, coupled energy, and heat loss to reproduce the temperature heating profile given in section 11.3.5. The conditions for each acid mixture and each batch containing the same specified number of vessels must be determined individually. Only identical acid mixtures and vessel models and specified numbers of vessels may be used in a given batch.

10.1.2 For cavity type microwave equipment, calibration is accomplished by measuring the temperature rise in 1 kg of water exposed to microwave radiation for a fixed period of time. The analyst can relate power in watts to the partial power setting of the system. The calibration format required for laboratory microwave systems depends on the type of electronic system used by the manufacturer to provide partial microwave power. Few systems have an accurate and precise linear relationship between percent power settings and absorbed power. Where linear circuits have been utilized, the calibration curve can be determined by a three-point calibration method (see Section 10.1.4). Otherwise, the analyst must use the multiple point calibration method (see Section 10.1.3). Assistance in calibration and software guidance of calibration are available in References 7 and 8.

10.1.3 Multiple point calibration involves the measurement of absorbed power over a large range of power settings. Typically, for a 600 W unit, the following power settings are measured: 100, 99, 98, 97, 95, 90, 80, 70, 60, 50, and 40% using the procedure described in Section 10.1.5. This data is clustered about the customary working power ranges. Nonlinearity has been encountered at the upper end of the calibration. If the system's electronics are known to have nonlinear deviations in any region of proportional power control, it will be necessary to make a set of measurements that bracket the power to be used. The final calibration point should be at the partial power setting that will be used in the test. This setting should be checked periodically to evaluate the integrity of the calibration. If a significant change is detected (± 10 W), then the entire calibration should be re-evaluated.

10.1.4 The three-point calibration involves the measurement of absorbed power at three different power settings. Power is measured at 100% and 50% using the procedure described in Section 10.1.5. From this 2-point line, determine the partial power setting that corresponds to the power, in watts, specified in the procedure to reproduce the heating profile specified in Section 11.3.6. Measure the absorbed power at that partial power setting. If the measured absorbed power does not correspond to the specified power within ± 10 W, use the multiple point calibration in Section 10.1.3. This point should also be used to periodically verify the integrity of the calibration.

10.1.5 Equilibrate a large volume of water to room temperature (22 ± 3 °C). One kg of reagent water is weighed (1,000.0 ± 0.1 g) into a fluorocarbon beaker or a beaker made of some other material that does not significantly absorb microwave energy (glass absorbs microwave energy and is not recommended). The initial temperature of the water should be 22 ± 3 °C measured to ± 0.05 °C. The covered beaker is circulated continuously (in the normal sample path) through the microwave field for 2 minutes at the desired partial power setting with the system's exhaust fan on maximum (as it will be during normal operation). The beaker is removed and the water is vigorously stirred. Use a magnetic stirring bar inserted immediately after microwave irradiation (irradiating with the stir bar in the vessel could cause electrical arcing) and record the maximum temperature within the first 30 seconds to ± 0.05 °C. Use a new sample for each additional measurement. If the water is reused (after making adjustments for any loss of weight due to heating), both the water and the beaker must have returned to 22 ± 3 °C. Three measurements at each power setting should be made.

The absorbed power is determined by the following relationship:

Eq. 1

Where:

P = the apparent power absorbed by the sample in watts (W) (joule sec^{-1})

K = the conversion factor for thermochemical calories sec^{-1} to watts (K= 4.184)

C_p = the heat capacity, thermal capacity, or specific heat (cal g^{-1} °C^{-1}) of water

m = the mass of the water sample in grams (g)

ΔT = the final temperature minus the initial temperature (°C)

t = the time in seconds (s)

Using the experimental conditions of 2 minutes (120 sec) and 1 kg (1000 g) of distilled water (heat capacity at 25 °C is 0.9997 cal g^{-1} °C^{-1}), the calibration equation simplifies to:

Eq. 2

NOTE: Stable line voltage is necessary for accurate and reproducible calibration and operation. The line voltage should be within manufacturer's specification. During measurement and operation the line voltage should not vary by more than ± 2 V (Reference 7). Electronic components in most microwave units are matched to the system's function and output. When any part of the high voltage circuit, power source, or control components in the system have been serviced or replaced, it will be necessary to recheck the system's calibration. If the power output has changed significantly (± 10 W), then the entire calibration should be re-evaluated.

11.0 SAMPLE PROCEDURE

11.1 Temperature control of closed vessel microwave instruments provides the main feedback control performance mechanism for the method. Method control requires a temperature sensor in one or more vessels during the entire digestion. The microwave decomposition system should sense the temperature to within ± 2.5 °C and permit adjustment of the microwave output power within 2 seconds.

11.2 All digestion vessels and volumetric ware must be carefully acid washed and rinsed with reagent water. When switching between highly concentrated samples and low concentrated samples, all digestion vessels (fluoropolymer or quartz liners) should be cleaned by leaching with hot (1:1) hydrochloric acid (greater than 80 °C, but less than boiling) for a minimum of two hours followed by hot (1:1) nitric acid (greater than 80 °C, but less than boiling) for a minimum of two hours. The vessels should then be rinsed with reagent water and dried in a clean environment. This cleaning procedure should also be used whenever the prior use of

the digestion vessels is unknown or cross contamination from prior sample digestions in vessels is suspected. Polymeric or glass volumetric ware and storage containers should be cleaned by leaching with more dilute acids (approximately 10% V/V) appropriate for the specific material used and then rinsed with reagent water and dried in a clean environment.

11.3 Sample Digestion

11.3.1 Measure a 45 mL aliquot of a well-shaken, homogenized sample using an appropriate volumetric measurement and delivery device, and quantitatively transfer the aliquot to an appropriate vessel equipped with a controlled pressure relief mechanism.

11.3.2 Add 5 ± 0.1 mL concentrated nitric acid or, alternatively, 4 ± 0.1 mL concentrated nitric acid and 1 ± 0.1 mL concentrated hydrochloric acid to the vessel in a fume hood (or fume exhausted enclosure). The addition of concentrated hydrochloric acid to the nitric acid is appropriate for the stabilization of certain analytes, such as Ag, Ba, and Sb and high concentrations of Fe and Al in solution. Improvements and optimal recoveries of antimony and silver upon addition of HCl have been described in the literature (Reference 7). The addition of hydrochloric acid may, however, limit the detection techniques or increase the difficulties of analysis for some detection systems.

CAUTION: *The addition of hydrochloric acid must be in the form of concentrated hydrochloric acid and not from a premixed combination of acids. A build-up of chlorine gas, as well as other gases, will result from a premixed acid solution. These gases may be violently released upon heating. This is avoided by adding the acid in the described manner.*

CAUTION: *Toxic nitrogen oxide(s) and chlorine fumes are usually produced during digestion. Therefore, all steps involving open or the opening of microwave vessels must be performed in a properly operating fume ventilation system.*

CAUTION: *The analyst should wear protective gloves and face protection.*

CAUTION: *The use of microwave equipment with temperature feedback control is required to control any unfamiliar reactions that may occur during the leaching of samples of unknown composition. The leaching of these samples may require additional vessel requirements such as increased pressure capabilities.*

11.3.3 The analyst should be aware of the potential for a vigorous reaction, especially with samples containing suspended solids composed of volatile or easily oxidized organic species. When digesting a matrix of this type, if a vigorous reaction occurs upon the addition of reagent(s), this sample represents a safety hazard. Do not leach the sample as described in this method due to the high potential for unsafe and uncontrollable reactions.

11.3.4 Seal the vessel according to the manufacturer's directions. Properly place the vessel in the microwave system according to the manufacturer's recommended specifications and, when applicable, connect appropriate temperature and pressure monitoring equipment to vessels according to manufacturer’s specifications.

11.3.5 This method is a performance based method, designed to achieve or approach consistent leaching of the sample through achieving specific reaction conditions. The temperature of each sample should rise to 170 ± 5 °C in approximately 10 minutes and remain at 170 ± 5 °C for 10 minutes, or for the remainder of the twenty-minute digestion period (References 3, 4, 6, and 7). The time vs. temperature and pressure profiles for the leaching of three simulated wastewater samples using Method 3015 are shown in Figure 1. The samples are composed of approximately 0.35 g SRM 2704 (Buffalo River Sediment) mixed in 45 mL double-deionized water. The figure demonstrates the temperature and pressure profiles for both the all-nitric digest (5 mL

concentrated nitric acid), and the nitric and hydrochloric mixed-acid digest (4 mL concentrated nitric acid and 1 mL concentrated hydrochloric acid). Also shown is the profile for the heating of the wastewater sample without addition of acids. When using temperature feedback control, the number of samples that may be simultaneously digested may vary, from one sample up to the maximum number of vessels that can be heated by the magnetron of the microwave unit according to the heating profile specified in this section. (The number will depend on the power of the unit, the number of vessels, and the heat loss characteristics of the vessels (Reference 7)).

11.3.5.1 Calibration control is applicable in reproducing this method provided the power in watts versus time parameters are determined to reproduce the specifications listed in Section 11.3.5. The calibration settings will be specific to the quantity of reagents, the number of vessels, and the heat loss characteristics of the vessels (Reference 7). If calibration control is being used, any vessels containing acids for analytical blank purposes are counted as sample vessels. When fewer than the recommended number of samples are to be digested, the remaining vessels should be filled with 45 mL water, and the acid mixture added, so that the full complement of vessels is achieved. This provides an energy balance, since the microwave power absorbed is proportional to the total absorbing mass in the cavity (Reference 7). Irradiate each group of vessels using the predetermined calibration settings. (Different vessel types should not be mixed.)

11.3.6 At the end of the microwave program, allow the vessels to cool for a minimum of 5 minutes before removing them from the microwave system. Cooling of the vessels may be accelerated by internal or external cooling devices. When the vessels have cooled to near room temperature, determine if the microwave vessels have maintained their seal throughout the digestion. Due to the wide variability of vessel designs, a single procedure is not appropriate. For vessels that are sealed as discrete separate entities, the vessel weight may be taken before and after digestion to evaluate seal integrity. If the weight loss of the sample exceeds 1% of the weight of the sample and reagents, then the sample is considered compromised. For vessels with burst disks, a careful visual inspection of the disk, in addition to weighing, may identify compromised vessels. For vessels with resealing pressure relief mechanisms, an auditory or a physical sign that can indicate whether a vessel has vented is appropriate.

11.3.7 Complete the preparation of the sample by carefully uncapping and venting each vessel in a chemical fume hood (or fume exhausted enclosure). Vent the vessels using the procedure recommended by the vessel manufacturer. Quantitatively transfer the sample to an acid-cleaned bottle. If the digested sample contains particulates which may clog nebulizers or interfere with injection of the sample into the instrument, the sample may be centrifuged (Section 11.3.7.1), allowed to settle (Section 11.3.7.2), or filtered (Section 11.3.7.3).

11.3.7.1 Centrifugation: Centrifugation at 2,000 - 3,000 rpm for 10 minutes is usually sufficient to clear the supernatant.

11.3.7.2 Settling: If undissolved material, such as SiO_2, TiO_2, or other refractory oxides, remains, allow the sample to stand until the supernatant is clear. Allowing a sample to stand overnight will usually accomplish this. If it does not, centrifuge or filter the sample.

11.3.7.3 Filtering: If necessary, the filtering apparatus must be thoroughly cleaned and prerinsed with dilute (approximately 10% V/V) nitric acid. Filter the sample through qualitative filter paper into a second acid-cleaned container.

11.3.8 The removal or reduction of the quantity of sample may be desirable for concentration of analytes prior to analysis. The chemistry and volatility of the analytes of interest should be considered and evaluated when using this alternative (Reference 7, 8). Sample evaporation in a controlled environment with controlled purge gas and neutralizing and collection of exhaust interactions is an alternative where appropriate. This manipulation may be performed in the microwave system, if the system is capable of this function, or external to the microwave system in more common apparatus(s). This option must be tested and validated to determine analyte retention and loss and should be accompanied by equipment validation possibly using the standard addition method and standard reference materials. For further information, see References 7 and 8 and Method 3052.

NOTE: *The final solution typically requires nitric acid to maintain appropriate sample solution acidity and stability of the elements. Commonly, a 2% (v/v) nitric acid concentration is desirable. Waste minimization techniques should be used to capture reagent fumes. This procedure should be tested and validated in the apparatus and on standards before using on unknown samples.*

11.3.9 Transfer or decant the sample into volumetric ware and dilute the digest to a known volume. The digest is now ready for analysis for elements of interest using appropriate elemental analysis techniques and/or SW-846 methods.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 Calculations: The concentrations determined are to be reported on the basis of the actual volume of the original sample.

12.2 Prior to use of the method, verify that the temperature sensing equipment is properly reading temperature. A procedure for verification is given in Section 6.1.2. This will establish the accuracy and precision of the temperature sensing equipment, which should be carried throughout the statistical treatment of the quality assurance data.

12.3 In calibrating the microwave unit (Section 10.0), the power absorbed (for each power setting) by 1 kg of reagent water exposed to 120 seconds of microwave energy is determined by the expression:

$$\text{Power (in watts)} = (T_1 - T_2)\ (34.86)$$

where: T_1 = Initial temperature of water (between 21 and 25 °C to nearest 0.1 °C)

T_2 = Final temperature of water (to nearest 0.1 °C)

12.4 Plot the power settings against the absorbed power (calculated in Section 12.3) to obtain a calibration relationship. Alternatively, use a microwave calibration program to analyze the calibration data (References 7 and 8). Interpolate the data to obtain the instrument settings needed to provide the wattage levels specified in Section 12.3.

13.0 METHOD PERFORMANCE

13.1 The fundamental analytical validation of Method 3015 with nitric acid has been performed (Reference 6). The results are shown in Table 1. Variations of 3015 including nitric acid and hydrochloric acid have also been published in the literature (References 5, 7, 9). The method has also been tested on a variety of matrices, including two simulated wastewater

matrices, one consisting of ~ 0.35 g sediment (SRM 2704) mixed with 45 mL double-deionized water, and the other consisting of ~ 0.35 g soil (SRM 4355) mixed with 45 mL double-deionized water. The results are shown in Tables 2 and 3, and are published in the literature (Reference 9).

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operations. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions, consult Less is Better: Laboratory Chemical Management for Waste Reduction, available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street, NW, Washington, DC 20036, (202) 872-4477.

15.0 WASTE MANAGEMENT

15.1 The Environmental Protection Agency requires that laboratory waste management practices be consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult The Waste Management Manual for Laboratory Personnel, available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street, NW, Washington, DC 20036, (202) 872-4477.

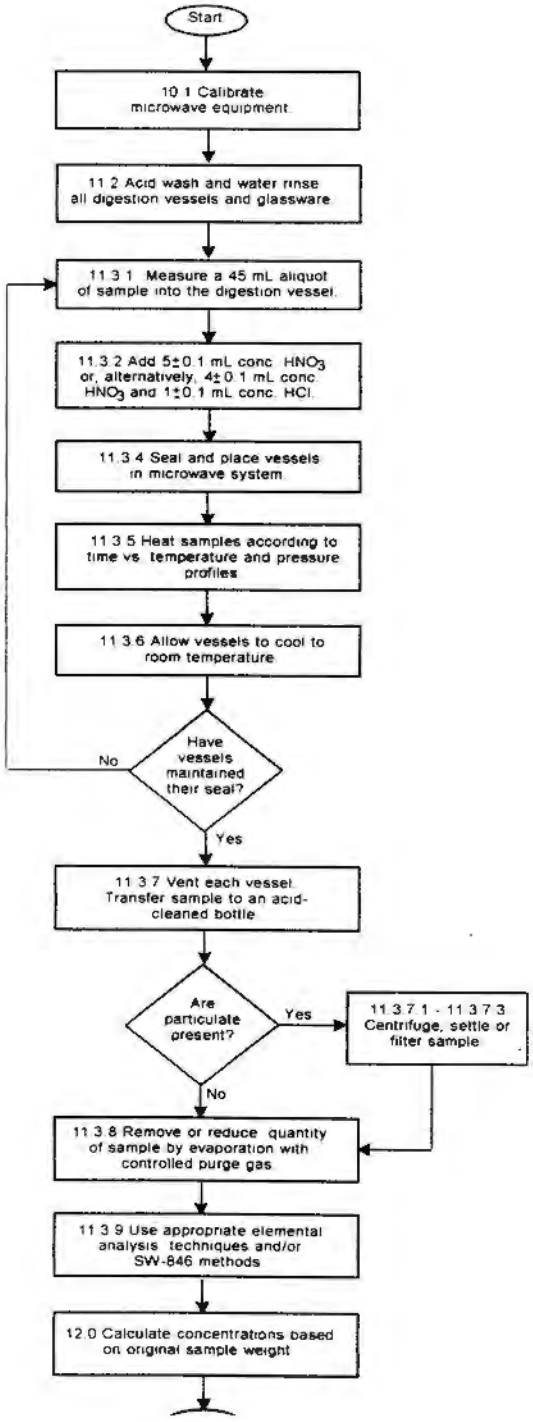
METHOD 3015A

MICROWAVE ASSISTED ACID DIGESTION OF AQUEOUS SAMPLES AND EXTRACTS



METHOD 3020A

ACID DIGESTION OF AQUEOUS SAMPLES AND EXTRACTS
FOR TOTAL METALS FOR ANALYSIS BY GFAA SPECTROSCOPY

1.0 SCOPE AND APPLICATION

1.1 This digestion procedure is used for the preparation of aqueous samples, mobility-procedure extracts, and wastes that contain suspended solids for analysis by furnace atomic absorption spectroscopy (GFAA) for the metals listed below. The procedure is used to determine the total amount of the metal in the sample.

1.2 Samples prepared by Method 3020 may be analyzed by GFAA for the following metals:

Beryllium	Lead
Cadmium	Molybdenum
Chromium	Thallium
Cobalt	Vanadium

NOTE: For the digestion and GFAA analysis of arsenic and selenium, see Methods 7060 and 7740. For the digestion and GFAA analysis of silver, see Method 7761.

2.0 SUMMARY OF METHOD

2.1 A mixture of nitric acid and the material to be analyzed is refluxed in a covered Griffin beaker. This step is repeated with additional portions of nitric acid until the digestate is light in color or until its color has stabilized. After the digestate has been brought to a low volume, it is cooled and brought up in dilute nitric acid such that the final dilution contains 3% (v/v) nitric acid. This percentage will vary depending on the amount of acid used to complete the digestion. If the sample contains suspended solids, it must be centrifuged, filtered, or allowed to settle.

3.0 INTERFERENCES

3.1 Interferences are discussed in the referring analytical method.

4.0 APPARATUS AND MATERIALS

4.1 Griffin beakers - 150-mL, or equivalent.

4.2 Watch glasses - ribbed or equivalent.

4.3 Qualitative filter paper or centrifugation equipment.

4.4 Funnel or equivalent.

4.5 Graduated Cylinder - 100mL.

4.6 Electric hot plate or equivalent - adjustable and capable of maintaining a temperature of 90-95°C.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent Water. Reagent water will be interference free. All references to water in the method refer to reagent water unless otherwise specified. Refer to Chapter One for a definition of reagent water.

5.3 Nitric acid (concentrated), HNO_3. Acid should be analyzed to determine levels of impurities. If method blank is < MDL, the acid can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be prewashed with detergents, acids, and water. Plastic and glass containers are both suitable. See Chapter Three, Step 3.1.3, for further information.

6.3 Aqueous wastewaters must be acidified to a pH of < 2 with HNO_3.

7.0 PROCEDURE

7.1 Transfer a 100-mL representative aliquot of the well-mixed sample to a 150-mL Griffin beaker and add 3 mL of concentrated HNO_3. Cover the beaker with a ribbed watch glass. Place the beaker on a hot plate and cautiously evaporate to a low volume (5 mL), making certain that the sample does not boil and that no portion of the bottom of the beaker is allowed to go dry. Cool the beaker and add another 3-mL portion of concentrated HNO_3. Cover the beaker with a non-ribbed watch glass and return to the hot plate. Increase the temperature of the hot plate so that a gentle reflux action occurs.

7.2 Continue heating, adding additional acid as necessary, until the digestion is complete (generally indicated when the digestate is light in color or does not change in appearance with continued refluxing). When the digestion is complete, evaporate to a low volume (3 mL); use a ribbed watch glass, not allowing any portion of the bottom of the beaker to go dry. Remove the beaker and add approximately 10 mL of water, mix, and continue warming the beaker for 10 to 15 minutes to allow additional solubilization of any residue to occur.

7.3 Remove the beaker from the hot plate and wash down the beaker walls and watch glass with water. When necessary, filter or centrifuge the sample to remove silicates and other insoluble material that may interfere with injecting the sample into the graphite atomizer. (This additional step can cause sample contamination unless the filter and filtering apparatus are thoroughly cleaned and prerinsed with dilute HNO_3.) Adjust to the final volume of 100 mL with water. The sample is now ready for analysis.

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One should be followed.

8.2 For each batch of samples processed, method blanks should be carried throughout the entire sample preparation and analytical process. These blanks will be useful in determining if samples are being contaminated. Refer to Chapter One for the proper protocol when analyzing blanks.

8.3 Replicate samples should be processed on a routine basis. Replicate samples will be used to determine precision. The sample load will dictate frequency, but 5% is recommended. Refer to Chapter One for the proper protocol when analyzing replicates.

8.4 Spiked samples or standard reference materials should be employed to determine accuracy. A spiked sample should be included with each batch of samples processed or 5% and whenever a new sample matrix is being analyzed. Refer to Chapter One for the proper protocol when analyzing spikes.

8.5 The concentration of all calibration standards should be verified against a quality control check sample obtained from an outside source. Refer to Chapter One for the proper protocol.

8.6 The method of standard addition shall be used for the analysis of all EP extracts. See Method 7000, Step 8.7, for further information.

9.0 METHOD PERFORMANCE

9.1 No data provided.

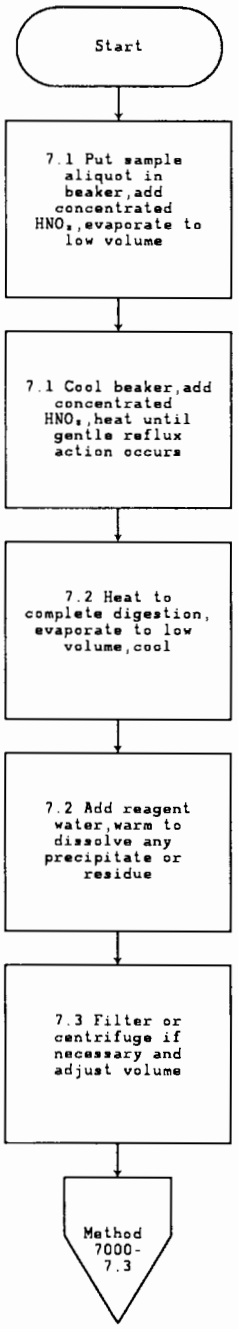
METHOD 3020A
ACID DIGESTION FOR AQUEOUS SAMPLES AND EXTRACTS
FOR TOTAL METALS FOR ANALYSIS BY GFAA SPECTROSCOPY



METHOD 3031

ACID DIGESTION OF OILS FOR METALS
ANALYSIS BY ATOMIC ABSORPTION OR ICP SPECTROMETRY

1.0 SCOPE AND APPLICATION

1.1 This method is an acid digestion procedure for analysis of oils, oil sludges, tars, waxes, paints, paint sludges and other viscous petroleum products for the sixteen toxic elements listed below:

Antimony	Arsenic	Barium	Beryllium
Cadmium	Chromium	Cobalt	Copper
Lead	Molybdenum	Nickel	Selenium
Silver	Thallium	Vanadium	Zinc

Other elements and matrices may be analyzed by this method if performance is demonstrated for the analytes of interest, in the matrix of interest, at the concentration levels of interest (see Section 8.0). The resulting digestate can be analyzed by either flame atomic absorption spectrometry (FLAA), graphite furnace atomic absorption spectrometry (GFAA), or inductively coupled plasma atomic emission spectrometry (ICP-AES).

1.2 The large concentration of manganese present in the digestate of Method 3031 can interfere with the determination of low concentrations of arsenic which is important for the recycled oil regulations. As an optional step, manganese may be removed from the digestate by forming a manganese phosphate precipitate. The remaining liquid can be analyzed by either flame atomic absorption spectrometry (FLAA) or inductively coupled plasma (ICP-AES). Chlorides can be removed by the use of nitric acid for analysis by graphite furnace atomic absorption spectrometry (GFAA) for arsenic. These clean-up procedures may be applicable to other elements as can be demonstrated by appropriate procedures (Sec. 7.11).

2.0 SUMMARY OF METHOD

2.1 A representative 0.5 g sample is mixed with 0.5 g of finely ground potassium permanganate and then 1.0 mL of concentrated sulfuric acid is added while stirring. A strong exothermic reaction occurs. The sample is then treated with 2 mL concentrated nitric acid. 10 mL of concentrated HCl is added and the sample is heated until the reaction is complete and is then filtered. The filter is washed with hot concentrated HCl. The filter paper is transferred to a digestion flask, treated with 5 mL of concentrated hydrochloric acid. The sample is brought to volume and analyzed by ICP-AES or FLAA.

WARNING: THIS PROCEDURE SHOULD NOT BE ATTEMPTED BY INEXPERIENCED PERSONNEL. MANY OF THE REACTIONS ARE STRONGLY EXOTHERMIC AND CAN RESULT IN SPLATTERING OR IN THE GENERATION OF GASES. GLOVES, FACESHIELDS, AND LAB COATS MUST BE WORN WHEN WORKING WITH ACIDS. IT IS STRONGLY RECOMMENDED THAT THE ADDITION OF SULFURIC ACID BE PERFORMED BEHIND A GLASS SHIELD OR SASH.

2.2 To remove the manganese, the digestate is neutralized with concentrated ammonium hydroxide. Water and ammonium phosphate are added and the digestate is stirred while a precipitate of manganese ammonium phosphate is formed. When the precipitation is complete,

the digestate is filtered. The ammonia is then boiled off. The sample is brought to volume and analyzed on either ICP-AES or FLAA. For GFAA analysis, the volume is reduced and allowed to cool. Concentrated HNO_3 is added and the solution is heated. When the reaction is complete, bring to volume and analyze by GFAA.

3.0 INTERFERENCES

3.1 Most grades of potassium permanganate have elemental impurities that will interfere with the analysis. It is important that the permanganate be checked for purity. Background correction setting on an ICP-AES that are appropriate to the digestates of other matrices will not be effective for the digestates of oils. Background correction settings must be chosen for this unique digestate. These digestates can have very high dissolved solids, which may necessitate the use of internal standards, dilutions, or method of standard addition. Manganese is a very strong emitter and has many analytical lines. Analytical wavelengths must be chosen with care to avoid or minimize spectral overlap. Inter-element correction for manganese can be used for those instruments with that capability.

3.2 Excess ammonium hydroxide will result in the solubilization of some manganese.

3.3 To ensure comparable viscosities and chemistries between samples and standards, all standards must be matrix matched to the respective digestates.

4.0 APPARATUS AND MATERIALS

4.1 Beakers - 250 mL, or equivalent.

4.2 Temperature sensing device, e.g. thermometer, thermistor, thermocouple, or equivalent, capable of measuring temperatures between 0 and 150°C.

4.3 Filter paper - Whatman No. 41, or equivalent.

4.4 Funnels - polypropylene, or equivalent.

4.5 Heating device, e.g. hot plate, heating block, microwave or equivalent.

4.6 Volumetric flasks, of suitable precision and accuracy.

4.7 Volumetric pipettes, of suitable precision and accuracy.

4.8 Stirring device, e.g. magnetic stirrer, glass rod or equivalent.

NOTE: All glassware should be acid washed.

5.0 REAGENTS

5.1 Reagent Water. Reagent water will be interference free. All references to water in the method refer to reagent water unless otherwise specified. Refer to Chapter One of SW-846 for a definition of reagent water.

5.2 Nitric acid, concentrated, reagent grade (conc. HNO_3). Acid should be analyzed to determine level of impurities. If method blank is < MDL, then the acid can be used.

5.3 Hydrochloric acid, concentrated, reagent grade (conc. HCl). Acid should be analyzed to determine level of impurities. If method blank is < MDL, then the acid can be used.

5.4 Sulfuric acid, concentrated, reagent grade (conc. H_2SO_4). Acid should be analyzed to determine level of impurities. If method blank is < MDL, then the acid can be used.

5.5 Potassium permanganate - Ultra-pure grade. Reagent should be analyzed to determine level of impurities. If method blank is < MDL, then the reagent can be used.

5.6 Organometallic standards - scandium and/or yttrium may be used as internal standards for most samples. Standards traceable to NIST Standard No. 1085, for wear metals in oil, may be used.

5.7 Base oil, analyte-free. Oil should be analyzed to determine level of impurities. If method blank is < MDL, then the reagent can be used.

5.8 Ammonium hydroxide, concentrated, reagent grade - Reagent should be analyzed to determine level of impurities. If method blank is < MDL, then the acid can be used.

5.9 Ammonium phosphate, reagent grade - Reagent should be analyzed to determine level of impurities. If method blank is < MDL, then the acid can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be pre-washed with detergents, acids, and water. See Chapter Three, Section 3.1.3, for further information.

6.3 Samples should be digested as soon as possible after arrival. Digestates may be kept for a period of 180 days in the case of most metals. See holding time table (Chapter Three) for specific metals of interest.

7.0 PROCEDURES

7.1 Homogenize sample and then take a representative sample of 0.5 g (± 0.01 g) and place in a beaker. Larger or smaller sample sizes can be used if needed.

> NOTE: Alternatively, with appropriate oils, H_2SO_4 and H_2O_2 may be used in repetition, with adjustments for stoichiometry, to permit the decomposition and reduce the dissolved solids content of digestate materials. If using an alternative reagent combination, equivalent performance must be demonstrated.

7.2 Add 0.5 g of potassium permanganate powder. If larger sample sizes are used, increase the amount of potassium permanganate so that the ratio of oil to potassium permanganate is still 1:1. Mix the oil and permanganate thoroughly until homogeneous. Thick oils and tars that cannot be mixed should be heated to achieve mixing (the oil may react mildly). It is important to record the amount of potassium permanganate used for each sample if analysis is by ICP-AES and correction is to be made for the amount of manganese.

If more than 10% of the sample is aromatic material, such as xylene, then the reaction will be incomplete. If this is the case, increase the amount of potassium permanganate. If the sample is a mixture of oil and other non-organic materials, reduce the amount of potassium permanganate.

NOTE: All steps requiring the use of acids should be conducted under a fume hood by properly trained personnel using appropriate laboratory safety equipment. This should include face shields and latex gloves.

7.3 Add 1.0 mL of concentrated H_2SO_4, and stir with an appropriate stirring device. If larger sample sizes are used, increase the volume of sulfuric acid so that ratio of oil to sulfuric acid is 1 g to 2 mL. The H_2SO_4 can be added dropwise or all at once, depending on analytical needs. (Generally, dropwise is preferred when low reporting limits are needed.)

NOTE: To prevent a strong exothermic reaction, H_2SO_4 should be added dropwise to all samples unfamiliar to the analyst and to all samples that are known to be highly reactive.

The reaction can take several seconds to begin, but when it occurs it will be very quick, vigorous, and exothermic. Generally larger sample sizes will react faster than smaller. Likewise, lower average molecular weight materials will react faster than heavier. Do not be mislead by an initial lack of reactivity. A grey-white vapor will be ejected from the beaker (SO_3) and splattering and bubbling can occur. The beaker will become very hot. This step is complete when no more gases are given off and the sample should be a thick black lumpy paste. Allow the beaker to cool as needed.

NOTE: Care must be taken when working with very light organic materials, such as diesel fuels, as they may flash. Generally, the lower the average molecular weight of the material correlates to a greater danger of flashing. The danger of flashing is reduced by adding the sulfuric acid dropwise.

NOTE: If more than 10% of the sample is aromatic material, such as xylene, only a little grey-white vapor will form. this will reduce accuracy and complicate nebulization. If there is a significant amount of non-hydrocarbon material, a sputtering reaction will occur and black MnO_2 particulates will be given off. See Section 7.2.

7.4 Add 2 mL of concentrated HNO_3 and stir. This reaction will be slightly exothermic. If larger sample sizes are used, it is not always necessary to increase the volume of HNO_3 proportionately, depending on analytical needs. Some reddish-brown vapor (NO_2) may be given off. Allow the reaction to continue until complete, that is when the digestate no longer gives off fumes. Allow the beaker to cool as needed.

7.5 Add 10 mL of concentrated HCl and stir. If larger sample sizes are used, it is not always necessary to increase the volume of HCl proportionately, depending on analytical needs. This reaction will be slightly exothermic and gas formation and foaming will occur. Lighter oils will foam more than will heavier oils. If excess foaming occurs, add water to prevent sample loss. Allow the beaker to cool as needed.

7.6 Heat the beaker until there is no further gas evolution. (temperature should not exceed 150° C to prevent volatilization). There may be additional foaming or other milder reactions which may result in overflow from the beaker. If excess foaming occurs, either remove the beaker from the heating source until foaming subsides or add sufficient water to prevent overflow. The final digestate should be a clear yellow liquid with black or dark reddish-brown particulates.

7.7 Filter the digestate through Whatman 41 filter paper and collect filtrate in a volumetric flask or beaker.

7.8 Wash the digestion beaker and filter paper, while still in the funnel, with no more than 5 mL of hot HCl.

NOTE: The purpose of this next step is to recover antimony, barium, and silver that may not have been complete solubilized. If the sample is not being prepared for these analytes, the next step may be skipped.

7.9 (Optional) After having washed the filter paper, remove the filter and residue from the funnel and place in back in the beaker. Add 5 mL of conc. HCl and place the beaker back on the heating source until the filter paper dissolves (temperature should not exceed 150°C ± 5°C to prevent volatilization). Remove the beaker from the heating source and wash the cover and sides with reagent grade water and then filter the residue and collect the filtrate in the same flask or beaker as in Sections 7.6 and 7.7. Allow the filtrate to cool and quantitatively transfer to a volumetric flask. Bring to volume.

7.10 (Optional) If the filtrate is collected in a beaker, the filtrate can be heated again to drive off excess HCl. This can reduce matrix effects in sample introduction (temperature should not exceed 150°C ± 5°C to prevent volatilization). When sufficient HCl has been removed, remove the beaker from the heating source, allow to cool, and then transfer the contents to a volumetric flask and bring to volume. However, if too much HCl is removed, barium, silver and antimony can be lost.

7.11 Analyze the filtrate by either ICP-AES or FLAA. Depending on the final volume selected, the total solids in the digestate may be high enough to cause nebulization problems. Problems due to high dissolved solids may be corrected by 1) following optional Section 7.9, 2) using internal standards, 3) using Flow Injection Analysis, or 4) using other matrix correction procedures.

Manganese Removal Steps

NOTE: The purpose of these next steps is to remove the manganese in the digest by precipitating it as manganese ammonium phosphate under alkaline conditions. Elements that do not form insoluble phosphates, such as arsenic, are filtered out and can be analyzed at lower concentrations.

7.12 Take the digestate, or portion of digestate and reduce the volume to remove as much HCl as possible without going below 10 mL. Then add conc. NH_4OH until pH is 7 or greater. For most matrices, the digestate will change colors (often from yellow to brown) at pH 7. A mild exothermic reaction will occur immediately.

7.13 Add at least 2 g ammonium phosphate for each 1 g of potassium permanganate used in the digestion and stir. An excess of phosphate is needed for good analyte recovery. Then add enough water and mix to ensure maximum precipitation. A pink or yellow silky amorphous precipitate, manganese ammonium phosphate, will form. If too much NH_4OH is used some of the manganese ammonium phosphate can be solubilized. Stir until precipitation is complete. Some ammonium phosphate may remain unreacted at the bottom of the beaker.

7.14 Filter the digestate through Whatman 41 filter paper (or equivalent) and collect filtrate in a volumetric flask or beaker.

7.15 Heat the filtrate to volatilize the ammonia (temperature should not exceed 150°C ± 5°C to prevent volatilization). the volume of filtrate can be reduced by heating to no less than 10 mL. If too much water is removed any ammonium chloride formed will solidify. If this occurs, either add enough water to dissolve the solids or filter out the solids and wash the residue with deionized water. A third alternative is to use nitric acid to destroy the ammonium chloride by using the step in Section 7.17.

7.16 The filtrate can be analyzed by ICP-AES or FLAA. The chlorides in the digestate will prevent the analysis by GFAA.

7.17 To analyze the digestate by GFAA, reduce the volume as much as possible. Cool and add sufficient conc. HNO_3 to drive off all chlorides. Heat gently and a mild exothermic reaction will occur. When no more reddish-brown gas (NO_2) is given off, the reaction is complete and the digestate can be cooled and taken to volume. This liquid can be analyzed by ICP-AES, FLAA, or GFAA.

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One should be followed.

8.2 For each analytical batch of samples processed, method blanks should be carried throughout the entire sample-preparation and analytical process. The blank will be useful in determining if samples are being contaminated. Do not subtract measured blank values from sample results. Use blanks to determine the source of contamination and eliminate it.

NOTE: This blank MUST include an analyte-free oil or explosive reactions can occur.

8.3 Duplicate samples should be processed on a routine basis. A duplicate sample is a sample brought through the whole sample preparation and analytical process. Refer to Chapter One for the proper protocol.

8.4 Organometallic standard reference materials (SRMs) or laboratory control samples spiked with organo-metallic standards should be employed to determine accuracy. Recoveries of SRMs and/or spikes should be +/- 25% of their true values.

9.0 METHOD PERFORMANCE

Refer to Tables 1, 2, 3, and 4.

Start
7.1 Homogenize sample.
7.2 Add potasium permanganate powder and heat.
7.3 Add concentrated H_2SO_4 to permanganate mixture.
7.4 Add concentration HNO_3.
7.5 Add concentrated HCl.
7.6 Heat beaker until there is no gas evolution.
7.7 Filter digestate.
7.8 Rinse filter paper and containment vessel into the flask containing digestate.
7.9 Add 5 mL concentrated HCl and reheat.
7.10 (Optional) Heat to drive off HCl.
7.11 Analyze by ICP-AES or FLAA.
Stop

METHOD 3040A

DISSOLUTION PROCEDURE FOR OILS, GREASES, OR WAXES

1.0 SCOPE AND APPLICATION

1.1 This method is used for the preparation of samples containing oils, greases, or waxes for analysis by flame atomic absorption spectrometry (FLAA) or inductively coupled plasma atomic emission spectrometry (ICP-AES) for the following metals:

Antimony	Copper
Arsenic	Iron
Barium	Lead
Beryllium	Manganese
Cadmium	Nickel
Chromium	Vanadium

1.2 This method is a solvent dissolution procedure, not a digestion procedure. This procedure can be very useful in the analysis of crude oil, but with spent or used oil high in particulate material it is less effective; most particulate material is not dissolved, and therefore the analysis is not a "total" metal determination. Because the highest percentage of metals is expected to be contained in the particulate material, oil analysis using Method 3040A will not provide an adequate estimate of the total metals concentration.

Caution: Overheating of oils and solvents can result in an explosion or fire, caution should be taken.

1.3 This method is applicable for the dissolution of multi-phasic aqueous wastes containing either oils, greases, or waxes. If a waste is multi-phasic it can be determined by using Method 3040A in combination with one of the other sample preparation methods.

Caution: The analysis of solvents in an ICP-AES should only be conducted after consultation with the manufacturer.

1.4 This method is suitable for conducting analyses in support of TCLP determinations if the percent solids, as conducted according to the procedures specified in the Method 1311, are below 0.5%.

2.0 SUMMARY OF METHOD

2.1 A representative sample is dissolved in an appropriate solvent (e.g., xylene, kerosene, or methyl isobutyl ketone). Organometallic standards are prepared using the same solvent, and the samples and standards are analyzed by FLAA or ICP-AES.

3.0 INTERFERENCES

3.1 Diluted samples and diluted organometallic standards are often unstable. Once standards and samples are diluted, they should be analyzed as soon as possible.

3.2 Solvent blanks should be used to rinse nebulizers thoroughly following aspiration of high concentration standards or samples.

3.3 Viscosity differences can result in different rates of sample introduction; therefore, all analyses shall be performed by the method of standard addition or internal standardization (only for ICP-AES). Peristaltic pumps often prove useful when analysis is performed by ICP-AES. In addition, a mass-flow controller may also alleviate some viscosity problems.

4.0 APPARATUS AND MATERIALS

4.1 Volumetric glassware or equivalent.

4.2 Analytical balance, 300 g capacity, minimum $\pm$ 0.01g.

4.3 Atomic absorption spectrometer: With an auxiliary oxidant control and a mechanism for background correction.

4.4 Inductively coupled plasma emission spectrometer system: With a mechanism for background correction and interelement interference correction. A peristaltic pump is optional.

5.0 REAGENTS

5.1 Methyl isobutyl ketone (MIBK).

5.2 Xylene.

5.3 Kerosene.

5.4 Organometallic standards - scandium and yttrium may be used as internal standards for most samples. Standards traceable to NIST Standard No. 1085, for wear metals in oil, may be used. (Two possible sources are Conostan Division, Conoco Speciality Products, Inc., P.O. Box 1267, Ponca City, OK 74601, and the U.S. Department of Commerce, National Institutes of Standards and Technology, Washington, DC 20234).

5.5 Base Oil.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 Samples shall be stored in an undiluted state at room temperature.

6.3 Samples should be processed and analyzed as soon as possible.

7.0 PROCEDURE

7.1 Weigh out a 2 gram representative sample of the waste or extract. Separate and weigh the phases if more than one phase is present.

7.2 Internal standards should be added to all samples at the mid-point of the concentration range, prior to dilution (the internal standard concentration may vary depending on your instrument or instrument configuration). Weigh an aliquot of the organic phase and dilute the aliquot in the appropriate solvent. Warming facilitates the subsampling of crude-type oils and greases and wax-type wastes. Xylene or kerosene are usually the preferred solvent for longer-chain hydrocarbons and for most analyses performed by ICP-AES. The longer-chain hydrocarbons usually require a minimum of a 1:10 (W/W) dilution, and lighter oils may require only a 1:5 (W/W) dilution if low detection limits are required.

7.3 Prepare a series of standards using the base oil and diluting by the same factor used for the samples. Add the internal standard before diluting. The concentration of the internal standard should be in the middle of the concentration range (The internal standard concentration may vary depending on your instrument or instrument configuration).

7.4 If the sample contains particulates, the result may be variable depending on whether the particles are aspirated into the instrument. Samples may be centrifuged after dilution to remove particulates from the solution prior to analysis.

7.5 All metals must be analyzed by the method of standard additions if an internal standard is not used. Because the method of standard additions can account only for multiplicative interferences (matrix or physical interferences), the analytical program must account for additive interference (nonspecific absorption and scattering in FLAA and nonspecific emission and interelement interference in ICP-AES) by employing background correction when using the ICP-AES.

7.6 Sample preparation for the method of standard additions can be performed on a weight or volume basis. Sample aliquots of viscous wastes should be weighed. Weigh identical amounts of the sample into three wide-mouth vials. Dilute the first vial such that the final concentration falls on the lower end of the linear portion of the calibration curve and significantly above the detection limit. Add sufficient standard to the second aliquot to increase the sample concentration by approximately 50%. Adjust the third sample concentration so that it is approximately twice that of the first. The second and third aliquots are then diluted to the same final volume as the first aliquot. Because of the wide variability in waste samples, and the problems encountered with analyzing them, the analyst's best judgement must be used to permit efficient use of this method.

7.7 Set up and calibrate the analytical instrumentation according to the manufacturer's directions for nonaqueous samples.

7.8 Report data as the weighted average for all sample phases.

$$[(P_1 \times C_1) + (P_2 \times C_2)]/P_T = C_F$$

P_1 = weight of the first phase (kg)

P_2 = weight of the second phase (kg)

C_1 = concentration of the first phase (mg/kg)

C_2 = concentration of the second phase (mg/kg)

P_T = weight of both phases (kg)

C_F = final concentration of waste (mg/kg)

7.9 For nonaqueous TCLP extracts and other samples where results are reported in "mg/L" units, the conversion from "mg/kg" to "mg/L" units can be done by determining the density of the liquid and converting mathematically.

8.0 QUALITY CONTROL

8.1 Preparation blanks (e.g., Conostan base oil or mineral oil plus reagents) should be carried through the complete sample-preparation and analytical process on a routine basis. These blanks will be useful in detecting and determining the magnitude of any sample contamination. Refer to Chapter One.

8.2 Replicate samples should be processed on a routine basis. Replicate samples will be used to determine precision. Refer to Chapter One.

8.3 Samples and standards should be diluted as closely as possible to the time of analysis.

8.4 All analyses must be performed by the method of standard additions if an internal standard is not used. See Method 7000, Section 8.7, for further information.

8.5 Data must be corrected for background absorption and emission and interelement interferences.

9.0 METHOD PERFORMANCE

9.1 Refer to Tables 1 and 2 for a single lab study.

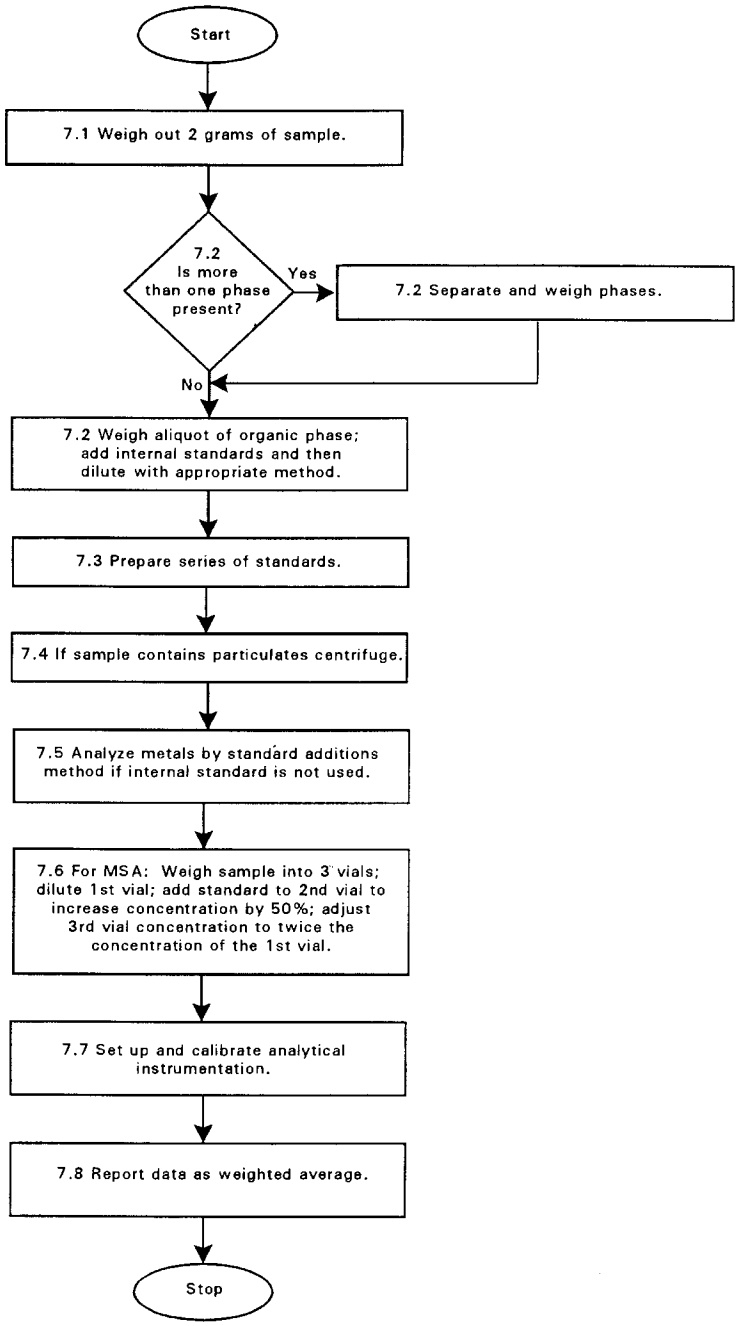
METHOD 3040A
DISSOLUTION PROCEDURE FOR OILS, GREASES, OR WAXES



METHOD 3050B

ACID DIGESTION OF SEDIMENTS, SLUDGES, AND SOILS

1.0 SCOPE AND APPLICATION

1.1 This method has been written to provide two separate digestion procedures, one for the preparation of sediments, sludges, and soil samples for analysis by flame atomic absorption spectrometry (FLAA) or inductively coupled plasma atomic emission spectrometry (ICP-AES) and one for the preparation of sediments, sludges, and soil samples for analysis of samples by Graphite Furnace AA (GFAA) or inductively coupled plasma mass spectrometry (ICP-MS). The extracts from these two procedures are not interchangeable and should only be used with the analytical determinations outlined in this section. Samples prepared by this method may be analyzed by ICP-AES or GFAA for all the listed metals as long as the detecion limits are adequate for the required end-use of the data. Alternative determinative techniques may be used if they are scientifically valid and the QC criteria of the method, including those dealing with interferences, can be achieved. Other elements and matrices may be analyzed by this method if performance is demonstrated for the analytes of interest, in the matrices of interest, at the concentration levels of interest (See Section 8.0). The recommended determinative techniques for each element are listed below:

FLAA/ICP-AES		GFAA/ICP-MS
Aluminum	Magnesium	Arsenic
Antimony	Manganese	Beryllium
Barium	Molybdenum	Cadmium
Beryllium	Nickel	Chromium
Cadmium	Potassium	Cobalt
Calcium	Silver	Iron
Chromium	Sodium	Lead
Cobalt	Thallium	Molybdenum
Copper	Vanadium	Selenium
Iron	Zinc	Thallium
Lead		
Vanadium		

1.2 This method is not a total digestion technique for most samples. It is a very strong acid digestion that will dissolve almost all elements that could become “environmentally available.” By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment. If absolute total digestion is required use Method 3052.

2.0 SUMMARY OF METHOD

2.1 For the digestion of samples, a representative 1-2 gram (wet weight) or 1 gram (dry weight) sample is digested with repeated additions of nitric acid (HNO_3) and hydrogen peroxide (H_2O_2).

2.2 For GFAA or ICP-MS analysis, the resultant digestate is reduced in volume while heating and then diluted to a final volume of 100 mL.

2.3 For ICP-AES or FLAA analyses, hydrochloric acid (HCl) is added to the initial digestate and the sample is refluxed. In an optional step to increase the solubility of some metals (see Section 7.3.1: NOTE), this digestate is filtered and the filter paper and residues are rinsed, first

with hot HCl and then hot reagent water. Filter paper and residue are returned to the digestion flask, refluxed with additional HCl and then filtered again. The digestate is then diluted to a final volume of 100 mL.

2.4 If required, a separate sample aliquot shall be dried for a total percent solids determination.

3.0 INTERFERENCES

3.1 Sludge samples can contain diverse matrix types, each of which may present its own analytical challenge. Spiked samples and any relevant standard reference material should be processed in accordance with the quality control requirements given in Sec. 8.0 to aid in determining whether Method 3050B is applicable to a given waste.

4.0 APPARATUS AND MATERIALS

4.1 Digestion Vessels - 250-mL.

4.2 Vapor recovery device (e.g., ribbed watch glasses, appropriate refluxing device, appropriate solvent handling system).

4.3 Drying ovens - able to maintain 30°C ± 4°C.

4.4 Temperature measurement device capable of measuring to at least 125°C with suitable precision and accuracy (e.g., thermometer, IR sensor, thermocouple, thermister, etc.)

4.5 Filter paper - Whatman No. 41 or equivalent.

4.6 Centrifuge and centrifuge tubes.

4.7 Analytical balance - capable of accurate weighings to 0.01 g.

4.8 Heating source - Adjustable and able to maintain a temperature of 90-95°C. (e.g., hot plate, block digestor, microwave, etc.)

4.9 Funnel or equivalent.

4.10 Graduated cylinder or equivalent volume measuring device.

4.11 Volumetric Flasks - 100-mL.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is questionable, analyze the reagent to determine the level of impurities. The reagent blank must be less than the MDL in order to be used.

5.2 Reagent Water. Reagent water will be interference free. All references to water in the method refer to reagent water unless otherwise specified. Refer to Chapter One for a definition of reagent water.

5.3 Nitric acid (concentrated), HNO_3. Acid should be analyzed to determine level of impurities. If method blank is < MDL, the acid can be used.

5.4 Hydrochloric acid (concentrated), HCl. Acid should be analyzed to determine level of impurities. If method blank is < MDL, the acid can be used.

5.5 Hydrogen peroxide (30%), H_2O_2. Oxidant should be analyzed to determine level of impurities. If method blank is < MDL, the peroxide can be used.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be demonstrated to be free of contamination at or below the reporting limit. Plastic and glass containers are both suitable. See Chapter Three, Section 3.1.3, for further information.

6.3 Nonaqueous samples should be refrigerated upon receipt and analyzed as soon as possible.

6.4 It can be difficult to obtain a representative sample with wet or damp materials. Wet samples may be dried, crushed, and ground to reduce subsample variability as long as drying does not affect the extraction of the analytes of interest in the sample.

7.0 PROCEDURE

7.1 Mix the sample thoroughly to achieve homogeneity and sieve, if appropriate and necessary, using a USS #10 sieve. All equipment used for homogenization should be cleaned according to the guidance in Sec. 6.0 to minimize the potential of cross-contamination. For each digestion procedure, weigh to the nearest 0.01 g and transfer a 1-2 g sample (wet weight) or 1 g sample (dry weight) to a digestion vessel. For samples with high liquid content, a larger sample size may be used as long as digestion is completed.

> NOTE: All steps requiring the use of acids should be conducted under a fume hood by properly trained personnel using appropriate laboratory safety equipment. The use of an acid vapor scrubber system for waste minimization is encouraged.

7.2 For the digestion of samples for analysis by GFAA or ICP-MS, add 10 mL of 1:1 HNO_3, mix the slurry, and cover with a watch glass or vapor recovery device. Heat the sample to 95°C ± 5°C and reflux for 10 to 15 minutes without boiling. Allow the sample to cool, add 5 mL of concentrated HNO_3, replace the cover, and reflux for 30 minutes. If brown fumes are generated, indicating oxidation of the sample by HNO_3, repeat this step (addition of 5 mL of conc. HNO_3) over and over until no brown fumes are given off by the sample indicating the complete reaction with HNO_3. Using a ribbed watch glass or vapor recovery system, either allow the solution to evaporate to approximately 5 mL without boiling or heat at 95°C ± 5°C without boiling for two hours. Maintain a covering of solution over the bottom of the vessel at all times.

NOTE: Alternatively, for direct energy coupling devices, such as a microwave, digest samples for analysis by GFAA or ICP-MS by adding 10 mL of 1:1 HNO_3, mixing the slurry and then covering with a vapor recovery device. Heat the sample to 95°C ± 5°C and reflux for 5 minutes at 95°C ± 5°C without boiling. Allow the sample to cool for 5 minutes, add 5 mL of concentrated HNO_3, heat the sample to 95°C ± 5°C and reflux for 5 minutes at 95°C ± 5°C. If brown fumes are generated, indicating oxidation of the sample by HNO_3, repeat this step (addition of 5 mL concentrated HNO_3) until no brown fumes are given off by the sample indicating the complete reaction with HNO_3. Using a vapor recovery system, heat the sample to 95°C ± 5°C and reflux for 10 minutes at 95°C ± 5°C without boiling.

7.2.1 After the step in Section 7.2 has been completed and the sample has cooled, add 2 mL of water and 3 mL of 30% H_2O_2. Cover the vessel with a watch glass or vapor recovery device and return the covered vessel to the heat source for warming and to start the peroxide reaction. Care must be taken to ensure that losses do not occur due to excessively vigorous effervescence. Heat until effervescence subsides and cool the vessel.

NOTE: Alternatively, for direct energy coupled devices: After the Sec. 7.2 "NOTE" step has been completed and the sample has cooled for 5 minutes, add slowly 10 mL of 30% H_2O_2. Care must be taken to ensure that losses do not occur due to excessive vigorous effervesence. Go to Section 7.2.3.

7.2.2 Continue to add 30% H_2O_2 in 1-mL aliquots with warming until the effervescence is minimal or until the general sample appearance is unchanged.

NOTE: Do not add more than a total of 10 mL 30% H_2O_2.

7.2.3 Cover the sample with a ribbed watch glass or vapor recovery device and continue heating the acid-peroxide digestate until the volume has been reduced to approximately 5 mL or heat at 95°C ± 5°C without boiling for two hours. Maintain a covering of solution over the bottom of the vessel at all times.

NOTE: Alternatively, for direct energy coupled devices: Heat the acid-peroxide digestate to 95°C ± 5°C in 6 minutes and remain at 95°C ± 5°C without boiling for 10 minutes.

7.2.4 After cooling, dilute to 100 mL with water. Particulates in the digestate should then be removed by filtration, by centrifugation, or by allowing the sample to settle. The sample is now ready for analysis by GFAA or ICP-MS.

7.2.4.1 Filtration - Filter through Whatman No. 41 filter paper (or equivalent).

7.2.4.2 Centrifugation - Centrifugation at 2,000-3,000 rpm for 10 minutes is usually sufficient to clear the supernatant.

7.2.4.3 The diluted digestate solution contains approximately 5% (v/v) HNO_3. For analysis, withdraw aliquots of appropriate volume and add any required reagent or matrix modifier.

7.3 For the analysis of samples for FLAA or ICP-AES, add 10 mL conc. HCl to the sample digest from 7.2.3 and cover with a watch glass or vapor recovery device. Place the sample on/in the heating source and reflux at 95°C ± 5°C for 15 minutes.

NOTE: Alternatively, for direct energy coupling devices, such as a microwave, digest samples for analysis by FLAA and ICP-AES by adding 5 mL HCl and 10 mL H_2O to the sample digest from 7.2.3 and heat the sample to 95°C ± 5°C, Reflux at 95°C ± 5°C without boiling for 5 minutes.

7.4 Filter the digestate through Whatman No. 41 filter paper (or equivalent) and collect filtrate in a 100-mL volumetric flask. Make to volume and analyze by FLAA or ICP-AES.

NOTE: Section 7.5 may be used to improve the solubilities and recoveries of antimony, barium, lead, and silver when necessary. These steps are optional and are not required on a routine basis.

7.5 Add 2.5 mL conc. HNO_3 and 10 mL conc. HCl to a 1-2 g sample (wet weight) or 1 g sample (dry weight) and cover with a watchglass or vapor recovery device. Place the sample on/in the heating source and reflux for 15 minutes.

7.5.1 Filter the digestate through Whatman No. 41 filter paper (or equivalent) and collect filtrate in a 100-mL volumetric flask. Wash the filter paper, while still in the funnel, with no more than 5 mL of hot (~95°C) HCl, then with 20 mL of hot (~95°C) reagent water. Collect washings in the same 100-mL volumetric flask.

7.5.2 Remove the filter and residue from the funnel, and place them back in the vessel. Add 5 mL of conc. HCl, place the vessel back on the heating source, and heat at 95°C ± 5°C until the filter paper dissolves. Remove the vessel from the heating source and wash the cover and sides with reagent water. Filter the residue and collect the filtrate in the same 100-mL volumetric flask. Allow filtrate to cool, then dilute to volume.

NOTE: High concentrations of metal salts with temperature-sensitive solubilities can result in the formation of precipitates upon cooling of primary and/or secondary filtrates. If precipitation occurs in the flask upon cooling, do not dilute to volume.

7.5.3 If a precipitate forms on the bottom of a flask, add up to 10 mL of concentrated HCl to dissolve the precipitate. After precipitate is dissolved, dilute to volume with reagent water. Analyze by FLAA or ICP-AES.

7.6 Calculations

7.6.1 The concentrations determined are to be reported on the basis of the actual weight of the sample. If a dry weight analysis is desired, then the percent solids of the sample must also be provided.

7.6.2 If percent solids is desired, a separate determination of percent solids must be performed on a homogeneous aliquot of the sample.

8.0 QUALITY CONTROL

8.1 All quality control measures described in Chapter One should be followed.

8.2 For each batch of samples processed, a method blank should be carried throughout the entire sample preparation and analytical process according to the frequency described in Chapter One. These blanks will be useful in determining if samples are being contaminated. Refer to Chapter One for the proper protocol when analyzing method blanks.

8.3 Spiked duplicate samples should be processed on a routine basis and whenever a new sample matrix is being analyzed. Spiked duplicate samples will be used to determine precision and bias. The criteria of the determinative method will dictate frequency, but 5% (one per batch) is recommended or whenever a new sample matrix is being analyzed. Refer to Chapter One for the proper protocol when analyzing spiked replicates.

8.4 Limitations for the FLAA and ICP-AES optional digestion procedure. Analysts should be aware that the upper linear range for silver, barium, lead, and antimony may be exceeded with some samples. If there is a reasonable possibility that this range may be exceeded, or if a sample's analytical result exceeds this upper limit, a smaller sample size should be taken through the entire procedure and re-analyzed to determine if the linear range has been exceeded. The approximate linear upper ranges for a 2 gram sample size:

Ag	2,000 mg/kg
As	1,000,000 mg/kg
Ba	2,500 mg/kg
Be	1,000,000 mg/kg
Cd	1,000,000 mg/kg
Co	1,000,000 mg/kg
Cr	1,000,000 mg/kg
Cu	1,000,000 mg/kg
Mo	1,000,000 mg/kg
Ni	1,000,000 mg/kg
Pb	200,000 mg/kg
Sb	200,000 mg/kg
Se	1,000,000 mg/kg
Tl	1,000,000 mg/kg
V	1,000,000 mg/kg
Zn	1,000,000 mg/kg

NOTE: These ranges will vary with sample matrix, molecular form, and size.

9.0 METHOD PERFORMANCE

9.1 In a single laboratory, the recoveries of the three matrices presented in Table 2 were obtained using the digestion procedure outlined for samples prior to analysis by FLAA and ICP-AES. The spiked samples were analyzed in duplicate. Tables 3-5 represents results of analysis of NIST Standard Reference Materials that were obtained using both atmospheric pressure microwave digestion techniques and hot-plate digestion procedures.

Start
7.1 Mix sample to homogeneity.
Select analytes.
Only for Sb, Ba, Pb, and As if required
All elements with appropriate recoveries
7.2 Add 10 mL 1:1 HNO3 and reflux for ~ 10 minutes.
7.2 Add 5 mL conc. HNO3 and reflux for 30 mins.; repeat until dig. is complete evaporate to 5 mL; cool.
7.2.1 - 7.2.2 Add 2 mL water and 3 mL 30% H2O2; continue to add 1 mL aliquots of H2O2 until bubbling subsides.
7.2.3 Reduce volume to ~5 mL.
FLAA or ICP-AES
Select Analytical Method
GFAA or ICP-MS
7.2.4 Filter/centrifuge, if necessary, dilute to 100 mL with water.
7.2.3 Analyze by GFAA or ICP-MS.
7.3 Add 10 mL concentrated HCl to the digest from 7.2.3 and cover reflux for 15 minutes.
7.4 Filter, make to volume.
7.4 Analyze by FLAA or ICP-AES.
7.5 Add 2.5 mL conc. HNO3 and 10 mL conc. HCl to sample reflux for 15 minutes.
7.5.1 Filter digestate and collect in volumetric flask.
7.5.1 Wash filter paper with 5 mL hot HCl and then with 20 mL hot reagent water. Collect in same 100 mL flask as filtrate.
7.5.2 Remove filter and residues and place back in vessel. Add 5 mL HCL and heat filter; collect in same flask as filtrate.
7.5.3 If precipitate forms add up to 10 mL HCl to dissolve. Dilute to volume.
7.5.3 Analyze by FLAA or ICP-AES.
7.6 Calculations.

METHOD 3051

MICROWAVE ASSISTED ACID DIGESTION OF SEDIMENTS, SLUDGES, SOILS, AND OILS

1.0 SCOPE AND APPLICATION

1.1 This method is applicable to the microwave assisted acid digestion of sludges, sediments, soils, and oils for the following elements:

Aluminum	Cadmium	Iron	Molybdenum	Sodium
Antimony	Calcium	Lead	Nickel	Strontium
Arsenic	Chromium	Magnesium	Potassium	Thallium
Boron	Cobalt	Manganese	Selenium	Vanadium
Barium	Copper	Mercury	Silver	Zinc
Beryllium				

1.2 This method is provided as an alternative to Method 3050. It is intended to provide a rapid multielement acid leach digestion prior to analysis so that decisions can be made about site cleanup levels, the need for TCLP testing of a waste and whether a BDAT process is providing acceptable performance. If a decomposition including hydrochloric acid is required for certain elements, it is recommended that Method 3050A be used. Digests produced by the method are suitable for analysis by flame atomic absorption (FLAA), graphite furnace atomic absorption (GFAA), inductively coupled plasma emission spectroscopy (ICP-ES) and inductively coupled plasma mass spectrometry (ICP-MS). Due to the rapid advances in microwave technology, consult your manufacturer's recommended instructions for guidance on their microwave digestion system and refer to the SW-846 "DISCLAIMER" when conducting analyses using Method 3051.

2.0 SUMMARY OF METHOD

2.1 A representative sample of up to 0.5 g is digested in 10 mL of concentrated nitric acid for 10 min using microwave heating with a suitable laboratory microwave unit. The sample and acid are placed in a fluorocarbon (PFA or TFM) microwave vessel. The vessel is capped and heated in the microwave unit. After cooling, the vessel contents are filtered, centrifuged, or allowed to settle and then diluted to volume and analyzed by the appropriate SW-846 method (Ref. 1).

3.0 INTERFERENCES

3.1 Very reactive or volatile materials that may create high pressures when heated may cause venting of the vessels with potential loss of sample and analytes. The complete decomposition of either carbonates, or carbon based samples, may cause enough pressure to vent the vessel if the sample size is greater than 0.25 g when used in the 120 mL vessels with a pressure relief device that has an upper limit of 7.5 ± 0.7 atm (110 ± 10 psi).

4.0 APPARATUS AND MATERIALS

4.1 Microwave apparatus requirements.

4.1.1 The microwave unit provides programmable power with a minimum of 574 W, which can be programmed to within ± 10 W of the required power. Typical units provide a nominal 600 W to 1200 W of power. Pressure, or especially temperature, monitoring and control of the microwave unit are desirable.

4.1.2 The microwave unit cavity is corrosion resistant and well ventilated.

4.1.3 All electronics are protected against corrosion for safe operation.

4.1.4 The system requires fluorocarbon (PFA or TFM) digestion vessels (120 mL capacity) capable of withstanding pressures up to 7.5 ± 0.7 atm (110 ± 10 psi) and capable of controlled pressure relief at pressures exceeding 7.5 ± 0.7 atm (110 ± 10 psi).

4.1.5 A rotating turntable is employed to insure homogeneous distribution of microwave radiation within the unit. The speed of the turntable should be a minimum of 3 rpm.

> CAUTION: Those laboratories now using or contemplating the use of kitchen type microwave ovens for this method should be aware of several signifant safety issues. First, when an acid such as nitric is used to assist sample digestion in microwave units in open vessels, or sealed vesselsequippedres, there is the potential for the acid gases released to corrode the safety devices that prevent the microwave magnetron from shutting off when the door is opened. This can result in operator exposure to microwave energy. Use of a unit with corrosion resistant safety devices prevents this from occurring.
>
> CAUTION: The second safety concern relates to the use of sealed containers without pressure relief valves in the unit. Temperature is the important variable controlling the reaction. Pressure is needed to attain elevated temperatures but must be safely contained. However, many digestion vessels constructed from certain fluorocarbons may crack, burst, or explode in the unit under certain pressures. Only unlined fluorocarbon (PFA or TFM) containers with pressure relief mecahnisms or containers with PFA-fluorocarbon liners and pressure relief mechanisms are considered acceptable at present.

Users are therefore advised not to use kitchen type microwave ovens or to use sealed containers without pressure relief valves for microwave acid digestions by this method. Use of laboratory-grade microwave equipment is required to prevent safety hazards. For further details consult reference 2.

CAUTION: There are many safety and operational recommendations specific to the model and manufacturer of the microwave equipment used in individual laboratories. These specific suggestions are beyond the scope of this method and require the analyst to consult the specific equipment manual, manufacturer and literature for proper and safe operation of the microwave equipment and vessels.

4.2 Volumetric graduated cylinder, 50 or 100 mL capacity or equivalent.

4.3 Filter paper, qualitative or equivalent.

4.4 Filter funnel, glass or disposable polypropylene.

4.5 Analytical balance, 300 g capacity, and minimum ± 0.01 g.

5.0 REAGENTS

5.1 All acids should be sub-boiling distilled where possible to minimize the blank levels due to metallic contamination. Other grades may be used, provided it is first ascertained that the reagent is of sufficient purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is questionable, analyze the reagent to determine the level of impurities. The reagent blank must be less than the MDL in order to be used.

5.1.1 Concentrated nitric acid, HNO_3. Acid should be analyzed to determine levels of impurity. If the method blank is less than the MDL, the acid can be used.

5.2 Reagent Water. Reagent water shall be interference free. All references to water in the method refer to reagent water unless otherwise specified (Ref. 3).

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All sample containers must be prewashed with detergents, acids and water. Plastic and glass containers are both suitable. See Chapter Three, sec. 3.1.3 of this manual, for further information.

6.3 Samples must be refrigerated upon receipt and analyzed as soon as possible.

7.0 PROCEDURE

7.1 Calibration of Microwave Equipment

NOTE: If the microwave unit uses temperature feedback control capable of replicating the performance specifications of the method, then the calibration procedure may be omitted.

7.1.1 Measurement of the available power for heating is evaluated so that absolute power in watts may be transferred from one microwave unit to another. For cavity type microwave equipment, this is accomplished by measuring the temperature rise in 1 kg of water exposed to microwave radiation for a fixed period of time. The analyst can relate power in watts to the partial power setting of the unit. The calibration format required for laboratory microwave units depends on the type of electronic system used by the manufacturer to provide partial microwave power. Few units have an accurate and precise linear relationship between percent power settings and absorbed power. Where linear circuits have been utilized, the calibration curve can be determined by a three-point calibration method (7.1.3), otherwise, the analyst must use the multiple point calibration method (7.1.2).

7.1.2 The multiple point calibration involves the measurement of absorbed power over a large range of power settings. Typically, for a 600 W unit, the following power settings are measured; 100, 99, 98, 97, 95, 90, 80, 70, 60, 50, and 40% using the procedure described in section

7.1.4. This data is clustered about the customary working power ranges. Nonlinearity has been commonly encountered at the upper end of the calibration. If the unit's electronics are known to have nonlinear deviations in any region of proportional power control, it will be necessary to make a set of measurements that bracket the power to be used. The final calibration point should be at the partial power setting that will be used in the test. This setting should be checked periodically to evaluate the integrity of the calibration. If a significant change is detected (±10 W), then the entire calibration should be reevaluated.

7.1.3 The three-point calibration involves the measurement of absorbed power at three different power settings. Measure the power at 100% and 50% using athe procedure described in section 7.1.4. From the 2-point line calculate the power setting corresponding to the required power in watts specified in the procedure. Measure the absorbed power at that partial power setting. If the measured absorbed power does not correspond to the specified power within ±10 W, use the multiple point calibration in 7.1.2. This point should also be used to periodically verify the integrity of the calibration.

7.1.4 Equilibrate a large volume of water to room temperature (23 ± 2°C). One kg of reagent water is weighed (1,000.0 g $\pm$ 0.1 g) into a

fluorocarbon beaker or a beaker made of some other material that does not significantly absorb microwave energy (glass absorbs microwave energy and is not recommended). The initial temperature of the water should be 23 ± 2°C measured to ± 0.05°C. The covered beaker is circulated continuously (in the normal sample path) through the microwave field for 2 minutes at the desired partial power setting with the unit's exhaust fan on maximum (as it will be during normal operation). The beaker is removed and the water vigorously stirred. Use a magnetic stirring bar inserted immediately after microwave irradiation and record the maximum temperature within the first 30 seconds to ± 0.05°C. Use a new sample for each additional measurement. If the water is reused both the water and the beaker must have returned to 23 ± 2°C. Three measurements at each power setting should be made.

The absorbed power is determined by the following relationship:

Eq. 1
$$P = \frac{(K)\ (C_p)\ (m)\ (\Delta T)}{t}$$

Where:

P = the apparent power absorbed by the sample in watts (W) (W=joule·sec^{-1})

K = the conversion factor for thermochemical calories·sec^{-1} to watts (=4.184)

C_p = the heat capacity, thermal capacity, or specific heat (cal·g^{-1}·$°C^{-1}$) of water

m = the mass of the water sample in grams (g)

ΔT = the final temperature minus the initial temperature (°C)

t = the time in seconds (s)

Using the experimental conditions of 2 minutes and 1 kg of distilled water (heat capacity at 25 °C is 0.9997 cal·g^{-1}·$°C^{-1}$) the calibration equation simplifies to:

Eq. 2
$$P = (\Delta T)\ (34.86)$$

> NOTE: Stable line voltage is necessary for accurate and reproducible calibration and operation. The line voltage should be within manufacturer's specification, and during measurement and operation should not vary by more than ±2 V. A constant power supply may be necessary for microwave use if the source of the line voltage is unstable.

Electronic components in most microwave units are matched to the units' function and output. When any part of the high voltage circuit, power source, or control components in the unit have been serviced or replaced, it will be necessary to recheck the units' calibration. If the power output has changed significantly (±10 W), then the entire calibration should be reevaluated.

7.2 All digestion vessels and volumetric ware must be carefully acid washed and rinsed with reagent water. When switching between high concentration samples and low concentration samples, all digestion vessels should be cleaned by leaching with hot (1:1) hydrochloric acid (greater than 80°C, but less than boiling) for a minimum of two hours followed with hot (1:1) nitric acid (greater than 80°C, but less than boiling) for a minimum of two hours and rinsed with reagent water and dried in a clean environment. This cleaning procedure should also be used whenever the prior use of the digestion vessels is unknown or cross contamination from vessels is suspected. Polymeric or glass volumetric ware and storage containers should be cleaned by leaching with more dilute acids (approximately 10% V/V) appropriate for the specific plastics used and then rinsed with reagent water and dried in a clean environment. To avoid precipitation of silver, ensure that all HCl has been rinsed from the vessels.

7.3 Sample Digestion

7.3.1 Weigh the fluorocarbon (PFA or TFM) digestion vessel, valve and capassembly to 0.001 g prior to use.

7.3.2 Weigh a well-mixed sample to the nearest 0.001 g into the fluorocarbon sample vessel equipped with a single-ported cap and a pressure relief valve. For soils, sediments, and sludges use no more than 0.500 g. For oils use no more than 0.250 g.

7.3.3 Add 10 ± 0.1 mL concentrated nitric acid in a fume hood. If a vigorous reaction occurs, allow the reaction to stop before capping the vessel. Cap the vessel and torque the cap to 12 ft-lbs (16 N-m) or according to the unit manufacturer's directions. Weigh the vessels to the nearest 0.001 g. Place the vessels in the microwave carousel.

CAUTION: Toxic nitrogen oxide fumes may be evolved, therefore all work must be performed in a properly operating ventilation system. The analyst should also be aware of the potential for a vigorous reaction. If a vigorous reaction occurs, allow to cool before capping the vessel.

CAUTION: When digesting samples containing volatile or easily oxidized organic compounds, initially weigh no more than 0.10 g and observe the reaction before capping the vessel. If a vigorous reaction occurs, allow the reaction to cease before capping the vessel. If no appreciable reaction occurs, a sample weight up to 0.25 g can be used.

CAUTION: All samples known or suspected of containing more than 5-10% organic material should be predigested in a hood for at least 15 minutes.

7.3.4 Properly place the carousel in the microwave unit according to the manufacturer's recommended specifications and, if used, connect the pressure vessels to the central overflow vessel with PFA-fluorocarbon tubes. Any vessels containing 10 mL of nitric acid for analytical blank purposes are counted as sample vessels. When fewer than the recommended number of samples are to be digested, the remaining vessels should be filled with 10 mL of nitric acid to achieve the full complement of vessels. This provides an energy balance since the microwave power absorbed is proportional to the total mass in the cavity (Ref. 4). Irradiate each group of sample vessels for 10 minutes. The temperature of each sample should rise to 175 °C in less than 5.5 minutes and remain between 170-180 °C for the balance of the 10 minute irradiation period. The pressure should peak at less than 6 atm for most soil, sludge, and sediment samples (Ref. 5). The pressure will exceed these limits in the case of high concentrations of carbonate or organic compounds. In these cases the pressure will be limited by the relief pressure of the vessel to 7.5 ± 0.7 atm (110 ± 10 psi). All vessels should be sealed according to the manufacturers recommended specifications.

7.3.4.1 Newer microwave units are capable of higher power (W) that permits digestion of a larger number of samples per batch. If the analyst wishes to digest more samples at a time, the analyst may use different values of power as long as they result in the same time and temperature conditions defined in 7.3.4. That is, any sequence of power that brings the samples to 175°C in 5.5 minutes and permits a slow rise to 175 - 180°C during the remaining 4.5 minutes (Ref. 5).

Issues of safety, structural integrity (both temperature and pressure limitations), heat loss, chemical compatibility, microwave absorption of vessel material, and energy transport will be considerations made in choosing alternative vessels. If all of the considerations are met and the appropriate power settings provided to reproduce the reaction conditions defined in 7.3.4, then these alternative vessels may be used (Ref. 1,2).

7.3.5 At the end of the microwave program, allow the vessels to cool for a minimum of 5 minutes before removing them from the microwave unit. When the vessels have cooled to room temperature, weigh and record the weight of each vessel assembly. If the weight of acid plus sample has decreased by more than 10 percent from the original weight, discard the sample. Determine the reason for the weight loss. These are typically attributed to loss of vessel seal integrity, use of a digestion time longer than 10 minutes, too large a sample, or improper heating conditions. Once the source of the loss has been corrected, prepare a new sample or set of samples for digestion beginning at 7.3.1.

7.3.6 Complete the preparation of the sample by carefully uncapping and venting each vessel in a fume hood. Transfer the sample to an acid-cleaned bottle. If the digested sample contains particulates which may clog nebulizers or interfere with injection of the sample into the instrument, the sample may be centrifuged, allowed to settle, or filtered.

7.3.6.1 Centrifugation: Centrifugation at 2,000-3,000 rpm for 10 minutes is usually sufficient to clear the supernatant.

7.3.6.2 Settling: Allow the sample to stand until the supernatant is clear. Allowing a sample to stand overnight will usually accomplish this. If it does not, centrifuge or filter the sample.

7.3.6.3 Filtering: The filtering apparatus must be thoroughly cleaned and prerinsed with dilute (approximately 10% V/V) nitric acid. Filter the sample through qualitative filter paper into a second acid-cleaned container.

7.3.7 Dilute the digest to a known volume ensuring that the samples and standards are matrix matched. The digest is now ready for analysis for elements of interest using the appropriate SW-846 method.

7.4 Calculations: The concentrations determined are to be reported on the basis of the actual weight of the original sample.

8.0 QUALITY CONTROL

8.1 All quality control data must be maintained and available for reference or inspection for a period of three years. This method is restricted to use by, or under supervision of, experienced analysts. Refer to the appropriate section of Chapter One for additional quality control guidance.

8.2 Duplicate samples should be processed on a routine basis. A duplicate sample is a sample brought through the whole sample preparation and analytical process. A duplicate sample should be processed with each analytical batch or every 20 samples, whichever is the greater number. A duplicate sample should be prepared for each matrix type (i.e., soil, sludge, etc.).

8.3 Spiked samples or standard reference materials should be included with each group of samples processed or every 20 samples, whichever is the greater number. A spiked sample should also be included whenever a new sample matrix is being analyzed.

9.0 METHOD PERFORMANCE

9.1 Precision: Precision data for Method 3051, as determined by the statistical examination of interlaboratory test results, is located in Tables 1 and 2.

9.2 Repeatability: If successive results are obtained by the same analyst with the same apparatus under constant operating conditions on identical test material, then the difference between these successive results will not, with 95% probability, exceed the repeatability value. For example, in the case of lead, an average of only 1 case in 20 would exceed

$$0.206\ x$$

in the long run, where x is one result in μg/g (Ref. 6).

9.3 Reproducibility: If two successive measurements are made independently by each of two different analysts working in different laboratories on identical test material, then the difference between the average result for each analyst will not, with 95% probability, exceed the reproducibility value. For example, in the case of lead, an average of only 1 case in 20 would exceed

$$0.303\ x$$

in the long run, where x is the average of two successive measurements in μg/g (Ref. 2).

As can be seen in Table 1, repeatability and reproducibility differ between elements, and usually depend on that element's concentration. Table 2 provides an example of how users of the method can determine expected values for repeatability and reproducibility; nominal values of lead have been used for this model (Ref. 6).

9.4 Bias: In the case of SRM 1085 - Wear Metals in Oil, the bias of this test method is different for each element. An estimate of bias, as shown in Table 3, is:

$$\text{Bias} = \text{Amount found} - \text{Amount expected.}$$

However, the bias estimate inherits both the uncertainty in the measurements made using Method 3051 and the uncertainty on the certificate, so whether the bias is real or only due to measurement error must also be considered. The concentrations found for Al, Cr, and Cu using Method 3051 fall within their certified ranges on SRM 1085, and 95% confidence intervals for Fe and Ni overlap with their respective certified ranges; therefore, the observed biases for these elements are probably due to chance and should be considered insignificant. Biases should not be estimated at all for Ag and Pb because these elements were not certified. Therefore, the only two elements considered in this table for which the bias estimates are significant are Mg and Mo.

[b]Repeatability and reproducibility were independent of concentration.
[c]Square root transformed variable based on one-way analysis of variance.

TABLE 2.
REPEATABILITY AND REPRODUCIBILITY FOR LEAD
BY METHOD 3051

Average Value	Repeatability	Reproducibility
50	10.3	15.2
100	20.6	30.3
200	41.2	60.6
300	61.8	90.9
400	82.4	121
500	103	152

All results are in mg/Kg

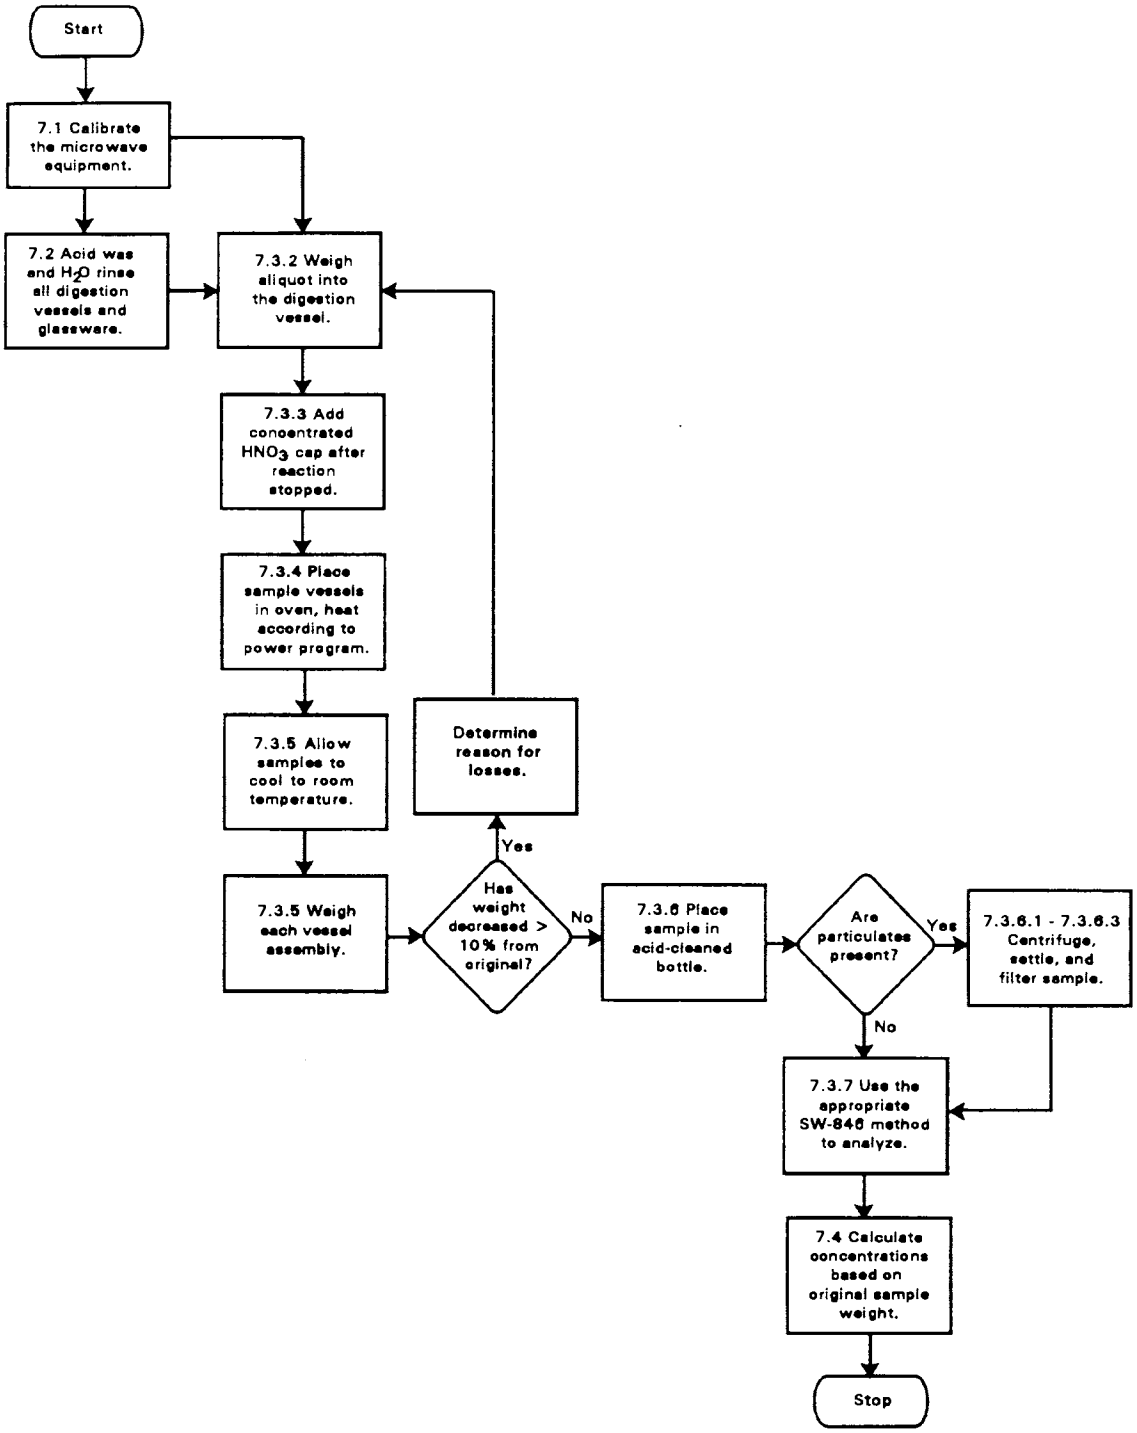
TABLE 3.
RECOVERY AND BIAS DATA FOR SRM 1085 - WEAR METALS IN OIL

Element	Amount Expected (Certified Range)	Amount Found* (95% Conf Interval)	Absolute Bias (µg/g)	Relative Bias (Percent)	Significant (due to more than chance)
Ag	(291)**	234±16	--	--	--
Al	296±4	295±12	-1	0	No
Cr	298±5	293±10	-5	-2	No
Cu	295±10	289±9	-6	-2	No
Fe	300±4	311±14	+11	+4	No
Mg	297±3	270±11	-27	-9	Yes
Mo	292±11	238±11	-54	-18	Yes
Mi	303±7	293±9	-10	-3	No
Pb	(305)**	279±8	--	--	--

All values in mg/Kg

*Results taken from table 4-7, Ref. 2.

**Value not certified, so should not be used in bias detection and estimation.



Start
7.1 Calibrate the microwave equipment.
7.2 Acid was and H_2O rinse all digestion vessels and glassware.
7.3.2 Weigh aliquot into the digestion vessel.
7.3.3 Add concentrated HNO_3 cap after reaction stopped.
7.3.4 Place sample vessels in oven, heat according to power program.
7.3.5 Allow samples to cool to room temperature.
7.3.5 Weigh each vessel assembly.
Has weight decreased > 10% from original?
Yes
Determine reason for losses.
No
7.3.6 Place sample in acid-cleaned bottle.
Are particulates present?
Yes
7.3.6.1 - 7.3.6.3 Centrifuge, settle, and filter sample.
No
7.3.7 Use the appropriate SW-846 method to analyze.
7.4 Calculate concentrations based on original sample weight.
Stop

USEPA METHOD 3051A

MICROWAVE ASSISTED ACID DIGESTION OF SEDIMENTS, SLUDGES, SOILS, AND OILS

1.0 SCOPE AND APPLICATION

1.1 This microwave extraction method is designed to mimic extraction using conventional heating with nitric acid (HNO_3), or alternatively, nitric acid and hydrochloric acid (HCl), according to EPA Methods 200.2 and 3050. Since these methods are not intended to accomplish total decomposition of the sample, the extracted analyte concentrations may not reflect the total content in the sample. This method is applicable to the microwave-assisted acid extraction/dissolution‡ of sediments, sludges, soils, and oils for the following elements:

Element		CASRN[a]
Aluminum	(Al)	7429-90-5*
Antimony	(Sb)	7440-36-0*
Arsenic	(As)	7440-38-2
Barium	(Ba)	7440-39-3*
Beryllium	(Be)	7440-41-7*
Boron	(B)	7440-42-8
Cadmium	(Cd)	7440-43-9
Calcium	(Ca)	7440-70-2
Chromium	(Cr)	7440-47-3*
Cobalt	(Co)	7440-48-4
Copper	(Cu)	7440-50-8
Iron	(Fe)	7439-89-6*
Lead	(Pb)	7439-92-1
Magnesium	(Mg)	7439-95-4*
Manganese	(Mn)	7439-96-5
Mercury	(Hg)	7439-97-6
Molybdenum	(Mo)	7439-98-7
Nickel	(Ni)	7440-02-0
Potassium	(K)	7440-09-7
Selenium	(Se)	7782-49-2
Silver	(Ag)	7440-22-4*
Sodium	(Na)	7440-23-5
Strontium	(Sr)	7440-24-6
Thallium	(Tl)	7440-28-0
Vanadium	(V)	7440-62-2*
Zinc	(Zn)	7440-66-6

[a]Chemical Abstract Service Registry Number

*Indicates elements which typically require the addition of HCl to achieve equivalent results with EPA Method 3050, as noted in reference 3.

‡Note: For matrices such as certain types of oils, this method may or may not provide total sample dissolution. For other matrices, such as soils and sediments, it should be considered an extraction method. Other elements and matrices may be analyzed by this method if performance is demonstrated for the analyte of interest, in the matrices of interest, at the concentration levels of interest (see Sec. 9.0).

1.2 This method is provided as an alternative to EPA Methods 200.2 and 3050. This method provides options for improving the performance for certain analytes, such as antimony, iron, aluminum, and silver by the addition of hydrochloric acid, when necessary. It is intended to provide a rapid multi-element acid extraction or dissolution prior to analysis so that decisions can be made about materials and site cleanup levels, the need for TCLP testing of a waste (see EPA Method 1311, Section 1.2, for further details), and whether a BDAT process is providing acceptable performance. Digests produced by the method are suitable for analysis by flame atomic absorption spectrophotometry (FLAA), graphite furnace atomic absorption spectrophotometry (GFAA), inductively coupled plasma atomic emission spectrometry (ICP-AES) and inductively coupled plasma mass spectrometry (ICP-MS). However, the addition of HCl may limit the methods of detection, or increase the difficulties of detection with some techniques.

Due to the rapid advances in microwave technology, consult your manufacturer's recommended instructions for guidance on their microwave digestion system.

2.0 SUMMARY OF METHOD
