1.0 INTRODUCTION

This Construction Completion Report (CCR) has been prepared to provide record documentation of a removal action (RA) that was conducted at three historic burial pits (i.e., Pits A, B, and C) within the Radiological Waste Burial Pit site (SEAD-12) at the Seneca Army Depot Activity (SEDA or Depot) in Seneca County, New York. Parsons Infrastructure & Technology Group Inc. (Parsons) was tasked under the United States Army Corps of Engineers (USACE) Contract Number W912DY-08-D-0003, Task Order No. 0003 to perform the removal action of military-related items from the burial pit locations within the SEAD-12 site.

The Seneca Army Depot is designated by the U.S. Environmental Protection Agency (EPA) as a federal facility on the National Priorities List (NPL) and by the State of New York as an inactive hazardous waste site. SEAD-12 is listed as one of the historic solid waste management units (SWMUs) within the Depot, and thus is subject to the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). As such, all work performed within the bounds of SEAD-12 that has potential environmental impacts is subject to review and approval by representatives of the EPA and the New York State Department of Conservation (NYSDEC).

Historic information and past geophysical and environmental investigations of SEAD-12 indicated that three burial pits (i.e., A, B, and C) were present in the northeastern portion of SEAD-12. Prior test pitting operations conducted as part of the SEAD-12 expanded site inspection (ESI) and the SEAD-12 remedial investigation (RI) indicated that buried material contained in the burial pits included an undefined quantity of military-related debris, other conventional forms of debris (e.g., construction and demolition [C&D] debris, miscellaneous debris, etc.), and fill material, all of which was covered by known thicknesses of native, overburden soil. The chemical analysis of soil and fill samples collected during the ESI and RI burial pit investigations indicated that finite concentrations of hazardous substances were present in the soil and the fill found at the burial pit sites, but that the concentrations identified did not pose any unacceptable levels of human health hazard or risk or threats to the environment. Further, characterization of radiologic constituents found in the burial pits indicated that levels of the residual radioactivity were generally consistent with the prevailing background levels in the region, and that no undo level of additional risk or hazard was associated with the materials that were present in the burial pits.

In 1995, the Department of Defense (DoD) designated the Seneca Army Depot Activity for closure under its Base Realignment and Closure (BRAC) process, and the Depot's military mission ceased in 2000. Since its designation for closure, the Army has been working to complete necessary investigations and required remedial actions to address environmental conditions and concerns previously identified at the Depot and to prepare the property for transfer to other parties for beneficial reuse. Since 2000, more than 8,500 acres of land, including portions of SEAD-12, have successfully been transferred or leased to other parties for alternative uses. One of the new owners of transferred property at the Depot is the Seneca County Industrial Development Authority (SCIDA). Recently, the SCIDA leased a portion of SEAD-12 to a private user who is now occupying buildings

and land that are located to the northwest and west of the historic Radiological Waste Burial Pit locations. The tenant has indicated that they are interested in increasing their holdings in SEAD-12 to allow for future expansion of their business. Such an expansion could result in greater access to all portions of SEAD-12, and could involve the eventual construction of new facilities in support of their continuing business.

In response to this potential expanded use of the SEAD-12 site, the Army decided that the contents of the historic burial pits should be excavated, so that they could be examined to determine what material was actually present in the burial pits and to allow the Army to secure any military-related materials contained prior to releasing the land to new users. In addition, the excavation of the historic burial pits would allow further analysis of all of the buried material (military-related, C&D, and miscellaneous debris, fill, etc.) to verify that unacceptable levels of previously unidentified contaminants were not present in the burial pits.

1.1 PURPOSE OF THE CONSTRUCTION COMPLETION REPORT

This CCR describes the actions performed during the excavation of three historic burial pit locations within SEAD-12. This CCR presents laboratory results, survey data, drawings, and associated documentation to demonstrate that the removal action was conducted and completed in a manner that is consistent with the requirements of a removal action that is performed under CERCLA.

The Army's goal at the historic Burial Pit locations within SEAD-12 was to prevent future access and exposure to buried military-related items by removing and securing them, pending any subsequent demilitarization and disposal. In addition, during the recovery of the military-related items and objects, if previously unidentified levels of hazardous substances were found associated and commingled with the buried debris and were determined to pose an unacceptable threat or risk to the environment or human health, the removal action would provide a mechanism through which the hazardous substances could be removed, treated, and disposed to mitigate or eliminate the concern.

1.2 DESCRIPTION OF THE SENECA ARMY DEPOT

The SEDA is a former military facility that was owned by the U.S. Government and operated by the Army between 1941 and 2000 when the SEDA's military mission ceased. The Depot occupied approximately 10,600 acres of land in the towns of Varick and Romulus in Seneca County, New York (see **Figure 1-1**). The Depot's historic military mission included receipt, storage, distribution, maintenance, and demilitarization of conventional ammunition, explosives, and special weapons.

In September 2000 the Army assumed the role of caretaker of the former Depot. As caretaker, the Army maintains control of the Depot's land until parcels are transferred to new owners for alternate uses. Areas in the Depot that are subject to continuing investigation and remedial action under the requirements of CERCLA remain under the control of the Army; however, to date more than 8,500 acres of the former Depot have been transferred to the Seneca County Industrial Development Authority (SCIDA), the State of New York, and other federal entities for reuse.

1.2.1 Future Land Use

The Seneca County Board of Supervisors established the Seneca Army Depot Local Redevelopment Authority (LRA) in October 1995 after the Depot was designated for closure under the DoD's BRAC process to prepare a plan for redevelopment of the SEDA property. The Land Reuse Plan was adopted and approved by the LRA and the Seneca County Board of Supervisors in 1996. The Reuse Plan designated parcels of land in the Depot into eight categories of preferred reuse: Planned Industrial/Office Development (PID), Warehousing, Prison, Conservation/Recreation, Institutional, Housing, Airfield/Special Events, and Federal to Federal Transfer. In 2005, the SCIDA revised the planned future use of Depot property by modifying portions of the original Conservation/Recreation parcels to include Institutional Training, Residential/Resort, Green Energy, Development Reserve, Training Area, and Utility uses. The planned future land use for SEAD-12 is currently designated as Institutional/Training as shown on **Figure 1-2**.

1.3 DESCRIPTION OF SEAD-12

SEAD-12 is located in the north central portion of the former SEDA within the former Weapons Storage Area (WSA) facility, also known as the "Q Area". Investigation of SEAD-12 originally began as the investigation of two separate areas, formerly designated as SEAD-12A (Radioactive Waste Burial Site – northeast corner of SEAD 12) and SEAD-12B (Radioactive Waste Burial Site – northeast of Buildings 803, 804, and 805). Locations of these two historic SEADs are shown in **Figure 1-3**. SEAD-12A encompassed an area measuring approximately 1,500 feet long by 900 feet wide that was suspected to have included up to five separate small burial pits. SEAD-12B encompassed an area measuring 300 feet long by 300 feet wide, and it was suspected to have included a 5,000-gallon storage tank and a small dry waste pit.

After the completion of the ESI of SEAD-12A and SEAD-12B in 1995, the bounds of SEAD-12 was expanded to that which is shown on **Figure 1-3** based on the similarity of the chemicals found at the two historic SEADs and the general history of the WSA, which suggested that similar constituents were likely to exist throughout the larger area. As redefined, SEAD-12 was enlarged to encompass an area of approximately 360 acres, which included all of the land of the original SEAD-12A and 12B, and most of the land located north of the storage igloos that are located within the boundary of the WSA. The only area not included within the bounds of the redefined SEAD-12, is land that is designated as SEAD-63, the Miscellaneous Components Burial Site, which is located in northwestern corner of the WSA.

Past environmental investigations and surveys within the greater SEAD-12 area, including the collection and analysis of soil, sediment, surface water, and groundwater samples for chemical contaminants and the real-time scanning and sampling of building surfaces and other environmental media for radiological constituents, focused on nine separate areas within the overall site. These sites are shown on **Figure 1-3** and are listed below:

- Building 819 and EM-27;
- Building 815, Building 816, and EM-28;

- Disposal Pits A/B (a portion of the former SEAD-12A);
- Disposal Pit C (a portion of former SEAD-12A);
- Dry Waste Disposal Pit (former SEAD-12B);
- EM-5;
- EM-6;
- Open areas; and
- Building 715 Wastewater Treatment Plant.

The results of the past environmental investigations indicated that with the sole exception of a small area in the vicinity of Building 813/814, there were no locations within SEAD-12 where residual contamination was identified at levels that posed unacceptable levels of risk or hazard to the environment or human health. In the vicinity of Building 813/814, groundwater in a single monitoring well (i.e., MW12-37) was found to be contaminated with trichloroethylene at a concentration above the federal maximum contaminant level (MCL) and the NYSDEC Class GA groundwater standard. A subsequent evaluation of the Building 813/814 and MW12-37 area including additional analysis of groundwater samples and the excavation and sampling and analysis of soil surrounding the affected well indicated that the groundwater contamination was not spread beyond the immediate area of the affected well, and that the source of the noted groundwater contamination appeared to be associated with soil contamination that extended back beneath the buildings. As a result of this finding, two land use controls will be implemented, monitored, and maintained at this location pending a future determination that the potential risk present at this location has been eliminated.

1.3.1 Location

The historic radiological burial pits identified as Disposal Pit A, B, and C, are all located in the area previously designated as SEAD-12A, which is located in the northeastern portion of SEAD-12. SEAD-12A is bounded to the north and east by the WSA's high-security fence line and Patrol Road, to the south by a wooded area that is located to the north of Buildings 813/814 and 815 between the WSA's eastern security fence and Service Road No. 1, and to the west by a narrow, north-south oriented row of trees that are located roughly 200 feet east of Service Road No. 1. Prior to the RA, land within SEAD-12A was classified as generally open and vacant, with intermixed areas that were either vegetated with grass, weeds, and scrub brush or free of vegetative cover.

The exact locations of the historic burial pits were identified using electromagnetic (EM) geophysical surveys that were performed as part of the SEAD-12 ESI. The locations of the identified burial pits areas are shown on **Figure 1-4**. Disposal Pit A and B are located in the southern part of the extended SEAD-12A open area, near the wooded area that forms the southern boundary of the overall disposal site area. The location of the tree line is approximated by the white area that is observed on **Figure 1-4**, while the largest red/pink/yellow feature is designated as Pit A and the smaller colored feature is Pit B located to the west of the larger Pit A. Disposal Pit C is located to the north and west of

Disposal Pit A and B, immediately east of the north-to-south oriented row of trees. Pit C is comprised of two separate components, Pit C1 which is the northernmost area that is shown by the blue coloration, and Pit C2 which is the southern area signified by yellow/pink/red and blue areas. The geophysical anomaly that is located to the north and east of Pit A, near the eastern perimeter fence is the remains of a historic security emplacement. The blue and yellow geophysical anomaly that is located west of Pits A and B and southwest of Pit C2 along Service Road No. 1 is a culvert that allows flow within an unnamed creek to flow from the east to the west.

1.3.2 Site Conditions

The regional topography in the vicinity of the burial pits is generally highest in the southeastern corner of the open area, east of Pits A and B, and slopes downward in a radial pattern to the north, west, east, and southwest. The small unnamed creek that flows under Service Road No. 1 passes to the south and southwest of the topographic high point, and through the wooded area south of the open area. The drainage ditches running parallel to Service Road No. 1 discharge captured surface water runoff into the unnamed creek at locations adjacent to the road culvert.

As is reported in the SEAD-12 RI Report, the site geology consists of gray Devonian shale bedrock having a thin upper weathered zone that is overlain by a Pleistocene age till. Topsoil covers much of the site. In developed areas, the till or weathered bedrock (where the till has been removed) is overlain by fill material consisting of reworked till. This stratigraphy is consistent over the entire site.

Figure 1-5 shows the location of geologic cross-sections that were developed for SEAD-12 during the RI, and two of these sections identified as B-B' (northern east-west section) and C-C' (north-south section) transect a portion of the Burial Pit area. The eastern part of transect B-B' (between the locations of MW-12-8 and MW12-12, see **Figure 1-6**) cuts through the location of Pits A and B and shows that as much as 10 – 12 feet of fill may be present in the immediate area of Disposal Pits A and B, and that this material overlies 1 to 2 feet of weathered shale, which in turn overlies competent shale. A localized bedrock high exists to the east of Burial Pit A, between the pit location and the eastern security fence. Beyond MW12-12, section B-B' turns northwards where it transects Pit C1 at location MW12-33 that is near the middle of the excavation where the stratigraphic information shows that roughly 6 feet of fill overlies an equal thickness of native till which in turn is above 1 to 2 feet of weather shale and then competent shale.

Similar cross sectional data from the area of Disposal Pits C1 and C2 (See northern end of **Figure 1-7** between locations MW12-34 and MW12-33) indicates that between 10 and 12 feet of fill and till overlies each 2 feet of fractured shale, which in turn overlies competent shale. The thicknesses of the fill and till layers each vary from 3 to 7 feet over the length of Pit C1 and thins out as it proceeds beyond the southern bound of Pit C2 at location MW12-14.

Historical groundwater data for SEAD-12 indicates that groundwater flow is predominantly to the west and northwest across the majority of the site. In the northeast corner of SEAD-12 in the vicinity of Burial Pits A, B, and C regional groundwater flow appears to be to the north and northwest. Local groundwater flow in the immediate vicinity of a relative high near Burial Pit C is to the north, northeast,

and northwest. Groundwater elevations range from a high of approximately 5.48 feet bgs (MW12-2) in the east, to a low of approximately 4.80 feet bgs (MW12-23) on the western side of the site. The horizontal groundwater gradient is steepest in the southern and central portions of the site at approximately 0.015 feet per foot (ft/ft). The horizontal groundwater gradient is flattest in the northern portion of the site at 0.007 ft/ft.

1.3.3 History

Land within SEAD-12 was believed to have been used for the disposal of laboratory wastes that originated from areas and operations located within the WSA. Available information suggests that the burial of material in this area occurred between the construction of the Depot in 1941 and 1980. In 1986, screening for radiological materials was performed in the area and a large amount of laboratory trash was excavated from five pits located in the southeastern corner of SEAD-12A. The waste was found in several concrete and one metal pipe, which were found under large concrete slabs (4 – 6 inches thick) that were apparent from the ground surface. The identified wastes were removed from the excavated pits and shipped off-site to an authorized radioactive waste landfill in December 1987.

The area of the Burial Pits was investigated again in 1994 as part of the ESI at the site. During this work, geophysical surveys (EM, ground penetrating radar [GPR], and seismic refraction), test pitting, and monitoring well installations were performed, and samples of soil, groundwater, surface water and sediment were collected and characterized for radiological and chemical contaminants. The results of this work suggested that buried materials were likely present at four locations within the greater SEAD-12A area (i.e., At Pits A and B and two locations in Pit C). Subsequent test pitting at these locations confirmed the presence of buried objects, including military-related items. The preliminary analysis of samples indicated that hazardous substances were present in all of the sampled media. As a result of this information, the Army expanded the focus of continuing investigations within the WSA to include additional area and buildings and authorized performance of a remedial investigation including a radiological survey throughout the larger SEAD-12 area.

The SEAD-12 RI was performed between 1998 and 2002. During the RI, the expanded SEAD-12 area (360 acres) was evaluated and expanded sampling and analysis of soil, groundwater, surface water and sediment were performed at the nine locations described above in **Section 1.3**. Sampling and analysis included the characterization of chemical and radiological constituents. At the conclusion of the RI, which included the results of the human health and ecological risk assessment, it was concluded that only two areas within the greater SEAD-12 footprint that required further consideration due to residual levels of contamination identified. These areas included EM-5 due to the apparent presence of residual levels of radiological constituents in excess of background, and in the vicinity of Building 813/814 due to the presence of trichloroethylene in the groundwater at well location MW12-237. The land including Burial Pits A, B, and C was not found to pose any unacceptable level of risk or inappropriate levels of non-carcinogenic hazard due to residual levels of contamination. However, the Army did acknowledge that additional work was required at Burial Pits A, B, and C to deal with the potential presence of military-related material in the historic burial pits.

1.4 REPORT ORGANIZATION

The first section of this report serves as an introduction to the CCR and provides SEAD-12 site history. **Section 2** details the pre-construction activities completed at SEAD-12. **Section 3** summarizes the construction activities, including the earthwork and confirmatory sample collection and analysis. **Section 4** addresses differences in actions conducted at SEAD-12 from the actions detailed in the Work Plan. **Section 5** presents a summary of the post-construction activities. **Section 6** presents the conclusions and recommendations. References are provided in **Section 7**.

Appendix A includes the Daily Reports; **Appendix B** provides chemical and radiological confirmatory soil sample results; **Appendix C** presents the waste characterization results for soil sent to the landfill; **Appendix D** provides the Health Physicist's (Cabrera Services, Inc.) Final Status Survey Report and summary of field support activities; **Appendix E** provides chain of custody documentation for the chemical and radiological analytical results; **Appendix F** presents case narratives for chemical constituents of concern; **Appendix G** presents the data validation memos for chemical contaminants of concern; **Appendix H** presents the update to the SEAD-12 RI Report human health risk assessment; **Appendix I** presents ambient air instrumentation dust monitoring results during the construction period; **Appendix J** presents the waste material manifests and truck load out log; **Appendix K** provides the analytical results for the water collected at the work site; and **Appendix L** includes the response to regulatory comments.

2.0 PRE-CONSTRUCTION ACTIVITIES

This section discusses the activities performed in preparation of the removal action implementation at the Burial Pits site in SEAD-12. These activities included a pre-mobilization site visit; a pre-construction kick-off meeting; a health and safety meeting; establishment of site access and security; clearing requirements; utility clearance; establishment of work and staging areas; staking and surveying; control of run-on and run-off waters; establishment of erosion and sedimentation controls; well abandonment; and disposal characterization and approval.

2.1 PRE-MOBILIZATION SITE VISIT

Personnel from Parsons visited the Depot during the week of June 29, 2009 to establish work zone boundaries, to lay out work zone grids, to conduct a pre-action topographic survey of the area, and to coordinate site access to the work zone. During this visit, Parsons' personnel also coordinated the mowing of the work zone with the Army and arranged to have a vendor spray the area to kill poison ivy that was prevalent within the work area site.

2.2 PRE-CONSTRUCTION MEETING

A project kick-off meeting was held at SEDA on July 6, 2009. Attendees included Parsons' Site Manager (SM), Site Health and Safety/Quality Control (SHS/QC Officer) and Project Manager (PM, by phone); the United States Army Corps of Engineers (USACE), Huntsville Center's Contracting Officer Representative (COR, by phone); the USACE New York District's Construction Manager; and personnel of the earthwork subcontractor S. St. George Enterprises, Inc. (St. George) of Fredonia, NY. SEDA, Parsons, and St. George coordinated administrative issues related to the project to ensure that the RA would proceed and be executed smoothly.

2.3 HEALTH AND SAFETY MEETING

All field activities conducted during the removal action were performed in general accordance with the site-specific health and safety plan (HSP) "Accident Prevention Plan and Generic Site Wide Health and Safety Plan for Seneca Army Depot Activity" (Parsons, 2005), which was prepared in accordance with Parsons' Safety, Health, and Risk Program (SHARP) Manual. The aforementioned generic HSP was supplemented with SEAD-12 specific information that was presented in the Supplemental Health and Safety Plan, Appendix A**,** *Draft Work Plan for Removal Action at the Waste Burial Radiological Sites (SEAD-12)* (Parsons, May 2009).

Access to the Parsons' Generic and Site-Specific Health and Safety Plan was provided to representatives of S. St. George and Cabrera Services, Inc. (Cabrera) during the development of their site-specific Health and Safety Plans for work at SEAD-12. St. George and Cabrera were each required to prepare and provide to Parsons for review, copies of their project-specific health and safety plans for the planned work at SEAD-12.

A health and safety indoctrination meeting was held at SEDA for all field crew members on July 13, 2009 prior to the commencement of intrusive construction activities at the SEAD-12 site. Parsons, St. George, and Cabrera personnel attended the health and safety meeting. A review of the project health

and safety requirements and procedures outlined in the Generic and Site-Specific Health and Safety Plan for Seneca Army Depot Activity and SEAD-12 was performed. Project coordination and communication and the scope of work were discussed.

Each workday morning, a brief "tool box" or "tail-gate" health and safety meeting was held prior to commencing the day's construction. The meeting topics addressed potential health and safety hazards specific to the site and the planned daily activities. Topics discussed included; ergonomics of hand held instruments; working in slippery conditions; heat stress and hydration; hot and cold weather procedures; slips, trips, and falls; avoiding poison ivy and ticks; glove usage; heavy equipment hand signals and high visibility personal protective equipment (PPE); proper handling and storage of TLD badges; safe work procedures of hand tools; excavation and trenching safety; safety glasses; and, frisk out procedures.

2.4 SITE SECURITY

The Burial Pits site (Pits A, B, and C) are located within SEAD-12, which encompasses approximately 360 acres of the former WSA that is located in the north-central portion of the Depot property. The entire WSA is surrounded by a multi-tiered perimeter chain-link security fence, which encase a perimeter patrol road. Access into and out of the former WSA is controlled through locked or manned security gates. Land within the northwestern portion of the former WSA is currently occupied by a tenant organization that maintains control of access into and out of their facilities. The Burial Pit sites (Pits A, B, and C) are located in the northeastern portion of the WSA, sandwiched between the northern and eastern perimeter security fences, Service Road No. 1, and an unnamed creek and wooded area that lay to the north of Buildings 813/814 and 815.

The Army provided site access to the field team prior to and during the performance of construction activities. All construction personnel and visitors accessed the work site from the southeast, entering the WSA through the southeastern unmanned (locked) security access point that is located off Fayette Road near its intersection with Igloo Road No. 1.

Site security was necessary to prevent exposure of unauthorized, unprotected individuals to the work area and its potential hazards. The area immediately surrounding the work zone was clearly marked through the use of signs, barrier rope, tape, or fencing. Security barriers ("K rails" or "Jersey" Barriers) were installed across Service Road No. 1 to the north and west of the work zone area to limit vehicular access into the work area by tenant organization personnel and to prohibit construction vehicles from traveling into the tenant occupied land.

Site security was enforced by the Site Health and Safety Officer (SHSO) or a designated alternate who ensured that only authorized personnel were allowed in the work area. The SHSO or designee also ensured that site entry during active operations was limited to personnel that possessed the required level of personal protective equipment (PPE), were trained under the requirements of Title 29 Code of Federal Regulations (CFR) 1910.120, and were part of a current medical monitoring program.

All visitors to the work site were required to report to the SM and/or the SHSO as soon as they arrived on site. The presence of visitors on site was recorded in the field logbook, including the visitor's name, company, date, time, and activities performed while on-site. All visitors to the work site, and persons working at the work site received site-specific training prior to entering the work area. The presence of visitors on-site, including the visitor's name, company, date, time, and activities performed while on site, was recorded in the site visitors log and in the daily reports provided in **Appendix A** of this report.

2.5 SITE CLEARING

Prior to the initiation of the removal action, land surrounding the Burial Pits site (Pits A, B, and C) was covered with tall grass, intermixed with poison ivy vines, sporadic small trees or brush and open, sparsely vegetated areas. Prior to the initiation of construction, the entire work zone area was sprayed with Roundup® to kill poison ivy and then the area was mowed. Grass and weed clippings were left in place.

2.6 IDENTIFICATION OF OBSTRUCTIONS AND UTILITIES

The earthwork subcontractor contacted Underground Facilities Protective Organization (UFPO) and worked with Parsons and the Army to locate and mark utilities and other obstructions in the immediate areas of the excavation sites and the supporting work/staging areas. No utilities or services were located in the immediate area of the excavation sites. The only obstructions identified in the work area were several historic monitoring wells, which initially were worked around, and subsequently removed during final portions of the construction phase activities.

2.7 ESTABLISHMENT OF WORK AND STAGING AREAS

The perimeters of the planned excavation sites and its support zone were marked using stakes.

The support area for the removal action activity was established in the unoccupied land located between Service Road No. 1 (to the west) and the north-south oriented row of trees (to the east) that bounded the western edge of the historic burial pit locations. The support zone area extended from the edge of the wooded area and unnamed creek at the southern end of the open grassland area northwards for a distance of 400 – 500 feet.

The support area was arranged to facilitate free and logical equipment movement to and from the work area to enhance safety, security, and minimize the likelihood that contaminants, if present, were introduced to new areas beyond the overall work site. Vehicular access into the support area was gained from Service Road No. 1 over a west-to-east oriented construction entrance that was constructed prior to the work and located in the southwestern corner of support area. The construction entrance was approximately 25 feet wide, and the road extended roughly 200 – 250 feet (west to east) into the open grassland area. The entrance was constructed by burying a 24-inch culvert pipe in the existing storm water drainage culvert located along the eastern edge of Service Road No. 1. The culvert pipe was covered with fabric and then gravel to stabilize the entrance and form the entry way from Service Road No. 1 into the support area and subsequently the work zone. A second construction entrance was built approximately 200 feet north of the first one along the edge of

Service Road No. 1, and these two entrances were connected by a "jug-handle" shaped earthen road which served as the truck turn-around and debris load out area during final material removal and disposal operations.

The support zone extended to north of the construction entrance, and included locations where excavated soil/fill/debris could be laid out for radiological scanning and removal of identified military-related items and other forms of debris, mechanical screening, and waste material stockpile/staging pending final disposal/deposition determinations. Waste streams from the handling/processing/screening operations were either staged in roll offs (for recyclable metals and other debris), B-25 boxes (military-related items and debris with radiological properties) or placed into soil/fill windrows located along the jug-handled road in the southwestern portion of the support area, but north of the construction entrance and road. The excavated soil layout and staging areas were lined with 6 millimeter (mil) polyethylene sheeting or equivalent material, and were used for temporary staging of excavated material pending processing (e.g., scanning or characterization sampling, screening, etc.) for disposal.

The construction entrance road extended through the north-to-south tree line where it extended into the work zone, passing immediately south of the location of Burial Pit C2. Beyond the tree line, the defined construction roadway gave way to meandering vehicular routes that marked how the construction vehicles passed from and around the excavation work zone to the support areas. Each of the excavation sites was bounded and marked with a 4-foot high orange construction fence that was installed around its perimeter as a safety measure.

Silt fences constructed of 2-foot high fabric mounted on wooden stakes were installed between the work and support zones and the wooded area that borders the work/support areas to the south and well as around the staging and handling (support) area, access roads, and along the road side ditches that parallel Service Road No. 1. Ditch checks constructed of hay bales were installed on the downstream ends of both of the drainage ditches that border Service Road No. 1 upgradient of the location where they discharge into the unnamed creek. The approximate locations of the silt fences and ditch checks are shown on **Figure 2-1**.

Available lithologic data from soil borings and test pit operations performed at the disposal pit locations during the RI indicated that the top 2.5 feet at Pit A and B, the top 0.5 feet at Pit C Area 1 north, and the top 3 feet at Pit C Area 2 south were likely to contain a large amount of clean overburden material overlying the actual burial pit locations. As such, a separate unlined soil staging area for the "clean" overburden soil was located north of Pit A and B, and east of Pit C and set aside for the temporary staging of clean overburden soils/fill that was identified as it was removed from the excavation sites.

The location of the support area including post excavation material handling, processing, and staging area, and the work zone area for this removal action are shown on **Figure 2-1**.

Temporary, impermeable pads were constructed for the screen plant, and equipment decontamination. The pads were bermed to prevent contaminated water run-off where it could impact clean areas. The

impermeable pads consisted of 40-millimeter polyethylene sheeting placed over several inches of clean sand laid atop the existing ground surface, and covered with several more inches of sand to protect the plastic sheeting. Pads were sloped to allow for the collection of runoff either back into the disposal pits and/or into sumps. The collected water was pumped to the frac tank.

Equipment leaving the work area was inspected prior to departure to ensure that loads were covered, and that clods of dirt and debris were not trapped between vehicle wheels, and that the exterior surfaces of the vehicles were not covered with excavated soil and debris. Construction equipment allowed within (i.e., beyond the jug handle load out area) the material handling and processing area and the excavation site area was scanned for residual radiation, and release surveys were processed before equipment was allowed to leave the work/processing site.

2.8 STAKING AND SURVEYING

The perimeters of the planned excavation areas were staked out based on coordinates from the design drawings included in the Work Plan. A pre-construction site survey was completed using a Trimble 5800 Real-Time Kinematic (RTK) global positioning system (GPS) unit. The Trimble GPS unit has an accuracy of ±10 millimeters (mm) for horizontal measurements and ±20 mm for vertical measurements.

A Trimble global positioning system (GPS)-enabled gamma walkover survey (GWS) was performed using a Ludlum 44-20 3”x3” sodium iodide (NaI) gamma scintillation detector to document the pre-excavation conditions of the ground surfaces at the presumed excavation pit footprints and planned support areas. The data were logged and uploaded to geographical information system (GIS) mapping software and statistically evaluated to identify any outliers or anomalies. The footprints of Pit A, Pit B, Pit C2, the sorting/segregation area, and the background area were scanned. Logged scans at Pit C1 were not performed prior to excavation; due to some initial setup problems with the GPS unit, only qualitative data were collected from the C1 footprint. One point of interest (POI) exhibiting above-background radiation levels was identified in the footprint of Pit C2. Further investigation of this location revealed a small piece of brown sandstone-like material for which subsequent laboratory analyses identified elevated levels of radionuclides associated with both the natural uranium and thorium decay series.

2.9 CONTROL OF RUN-ON AND RUN-OFF WATERS

Run-on waters in the excavation area were controlled by installing berms and/or ditches to divert storm water runoff from clean areas around the areas of excavation. Berms were placed upgradient of open excavation areas as work proceeded. The berms were constructed of clean, native soil from the site or hay bales. The run-on, run-off, and erosion control measures were inspected daily and minor repairs were completed as needed.

Run-off waters were retained within the excavation area through use of berms or hay bales and were generally allowed to infiltrate or evaporate. Storm event water and groundwater entering the excavations and materials staging areas were captured and periodically pumped into a tank for temporary storage pending determination of final disposition.

2.10 ESTABLISHMENT OF EROSION AND SEDIMENTATION CONTROLS

Erosion and sedimentation controls, such as silt fencing and hay bales, were installed in downgradient areas during operations to prevent migration of sediments and erosion. Prior to beginning any excavation work, temporary silt fencing was erected between the work area (i.e., Disposal Pit sites and the support/laydown area) and downgradient surrounding areas (i.e., wooded area and the unnamed creek to the south and drainage ditches bordering Service Road No. 1 to the west) to prevent contaminated sediment transport. As discussed in Section 2.4, hay bale ditch checks were also installed in the two drainage ditches that run on either side of and parallel to Service Road No. 1 at locations upgradient of where the drainage ditches discharge into the southeast to westerly trending unnamed creek that flows to the south of the historic burial pit site. The temporary silt fencing was maintained throughout the project and will not be removed until permanent vegetation has been re-established.

Temporary erosion control measures, including excavation slope stabilization benches, soil berms and swales exterior to the excavations, and silt fence emplacements were constructed around each of the open excavation sites to control surface water run-on/run-off and soil migration to outlying areas. Additionally, once excavated soils was placed into the Overburden/C1 stockpile, temporary silt fencing was added to the east, north, and northwest of this area to prevent sediment migration into lower lying areas.

3.0 CONSTRUCTION ACTIVITIES

This section documents construction-phase activity associated with the removal action of military-related items at the Burial Pits site that were performed by the Army in SEAD-12. Construction activities began with the mobilization of personnel and equipment to the work site by Parsons and subcontractors, S. St. George Enterprises, Inc., and Cabrera Services, Inc. on July 13, 2009. All construction activities were completed by November 4, 2009, by which time Parsons, St. George, Cabrera, and other subcontracted organizations had all demobilized from the work site. All construction activities that took place at SEDA were documented in daily reports (**Appendix A**).

3.1 SITE PREPARATION AND MOBILIZATION

The field crew and the equipment were mobilized to the site on July 13, 2009. Construction equipment mobilized to the site initially included an excavator, a bulldozer, articulated off-road trucks, a loader, a water pump, and a water storage tank. During the continuation of the removal action, additional construction equipment was mobilized to the site on an as-needed basis and the additional pieces used included a mechanical screening plant, skid steers, roll-offs, a York rake, flatbed trucks, forklifts, a New Holland tractor, Baker tanks, additional dozers and loaders, and over-the-road transport vehicles for transport to material disposal or recycling locations.

Radiological survey equipment mobilized to the site included an Alpha Spectra FIDLER with Ludlum 2221, for low-energy gamma detection; a Ludlum 43-93 with Ludlum 2360, for alpha and beta detection; a Bicron MicroRem, for exposure rate measurement; a Ludlum 2929, for alpha/beta measurements of smear samples and air filters; a Ludlum 44-9 with Ludlum 12, for beta/gamma frisking of personnel and equipment; a breathing zone air sampler and filters; and appropriate instrument check sources. Ancillary equipment deployed to the work site included GPS surveying equipment, a Photo-ionization Detector for VOCs, Schonstedt magnetic detectors, Thermo DataRAM DR-4000 real-time ambient dust monitors, a ground conductivity meter EM31-SH, and thermoluminescent dosimeters.

3.2 HEALTH AND SAFETY DURING CONSTRUCTION

At the start of each work day, all on-site workers attended a daily health and safety briefing conducted by Parsons' SHSO. The daily health and safety "tailgate" or "toolbox" meetings were mandatory for all subcontractor and Parsons personnel working at the site. At each meeting, the SHSO discussed PPE needs for that day and any potential hazards associated with the day's scheduled activities. The topics covered and all attendees at each daily briefing were documented, and the records were stored by the SHSO in the project files. Visitors to the work site were required to review the project Health and Safety Plan (Parsons, 2006b) and attend a site-specific health and safety briefing prior to entering the work site or support area.

All primary site personnel (i.e., those with a long-term presence, e.g., the SHSO, Cabrera's radiation technician [rad tech], St. George's foreman, operators, laborers, etc.) wore personnel thermoluminescent dosimetry (TLD) badges to monitor for evidence of exposure to ionizing radiation. The badges were individually assigned and were only worn on the site during hours of

operation. All badges were returned to the SHSO at the end of each work day and stored at the site office. Additionally, all site personnel were "frisked out" ("real-time scan") of the job site at the end of each work day to ensure that no radiological contaminants were transported away from the site.

During construction operations, all excavated materials were scanned in real-time with field monitoring equipment for indications of radioactivity or elevated levels of volatile organic compounds. Any excavated material that exhibited signs of radiation above regional background levels; contamination by other potential hazardous substances as assessed by hand-held photoionization detectors (PIDs) for VOCs or by visible signs of staining or soil discoloration or staining; or which showed visible evidence of the presence of intermingled debris was segregated from other lesser/non-contaminated excavated material in the material handling and staging areas.

3.3 DUST CONTROL AND AIR MONITORING

Air monitoring measurements were collected periodically during the first three weeks of the removal action (July 13 – July 30, 2009), during periods when the greatest amount of excavation and material handling activities occurred. Air monitoring frequency decreased once the majority of the disposal pit excavation, transport, and material layout operations, which required more vehicular travel, were completed and site activities moved more into material sorting, screening and staging which involved shorter driving distances and fewer trips. The data collected during the monitoring are presented in **Appendix I**. The presented data show that fugitive dusts were not identified as a concern during the excavation phase of the work due to the low number and slow operating speeds of site vehicles (e.g., articulated trucks, excavator, dozer, etc.). Furthermore, the clay-till composition of the native soil materials found at the site tends to clod which inherently reduces windborne dust levels. The professional judgments of the site manager and the site health and safety officer dictated when air monitoring and conventional methods of dust suppression (e.g., water spraying) were used to control dust generated during construction.

3.4 REMOVAL ACTION CONSTRUCTION ACTIVITIES

During the development of the Work Plan and continuing until the initial excavations at the burial pit sites began, the Army did not believe that further contaminant characterization was necessary for the materials contained in the burial pits. This belief was based on the results of the SEAD-12 ESI and RI sampling, test pitting, and risk assessment findings which indicated that unacceptable levels of chemical or radiological contaminants were not present at any of the burial pit sites and no unacceptable levels of environmental or human health hazard or risk were indicated for the historic disposal pits. This belief was further supported by the results and findings of the non-time critical removal action (NTCRA) performed at SEAD-63 (Miscellaneous Components Burial Site), a separate burial pit site located within the WSA, where excavated debris, including military related items, were not found to exhibit elevated levels of radioactivity and were not found to be commingled with conventional hazardous substances. As such, the stated objective of the removal action at the Burial Pits site was to:

- Excavate, segregate, and secure military-related materials from other debris and soil that are present in Burial Pit A/B and Burial Pit C within SEAD-12 to prevent public access to the classified or sensitive military-related material.

Even though the Army's motivation for the removal action focused on the recovery and securing of military-related items, provisions were included for the recovery and disposal of other forms of debris and for the characterization of materials that were identified and found to contain hazardous chemical or radiologic substances. Contingency work objectives were also documented in the Work Plan and included provisions to:

- Provide the Army access to other buried debris, if determined necessary, so it can be recovered, characterized, and subsequently transported off-site to licensed or permitted locations (e.g., landfills or recyclers) for disposal or reprocessing.
- Characterize, treat as necessary, and transport and dispose of any non-military related materials found to contain hazardous chemical or radiological substances off-site at licensed landfills in accordance with solid, hazardous, and/or radiological waste regulations.
- Verify that the Burial Pits A/B and C areas are free of classified military-related items and other forms of debris so that they can be released for unrestricted use and unlimited exposures.

Shortly after beginning the excavation activities at the SEAD-12 burial pit locations, the Army determined that the pits contained a greater number and a wider variety of military-related items than had been expected, and real-time radiological scans of many of the recovered military-related items showed the presence of radioactivity at, or modestly above, background levels. In addition, the debris recovered from the burial pits contained quantities of metallic components that had potential value as recycled materials.

Based on these findings, the Army and the project team modified their planned excavation, scanning, segregation, staging, handling, and processing operations to ensure that all excavated materials were fully characterized and evaluated before any final disposition determinations were made and before any site closeout operations were initiated and completed. Specific work changes implemented included:

- More frequent and thorough real-time radiological scanning of all excavated materials;
- Expanded excavated material processing and handling operations to ensure that all military-related items were recovered, all materials showing elevated levels of residual radiological activity were investigated and characterized, and all metal components of potential recycle value were recovered;
- Expanded post-removal characterization and handling of all military-related items to assess their condition and to secure them pending their transfer to another Army (non-SEDA) entity/authority for final demilitarization, disposal determinations, and actions;

- Expanded geophysical and physical surveys of all excavation locations to verify the removal of all identifiable debris prior to demobilization of personnel and equipment from the work sites;
- Collection and analysis of confirmatory samples from all excavation sites for radiological and chemical contaminants of concern (RCOCs and COCs, respectively);
- Collection and analysis of confirmatory samples from segregated overburden soil for radiological and chemical contaminants to confirm its suitability as backfill material; and,
- Implementation of more comprehensive equipment, personnel assessment, and demobilization procedures prior to daily and final job closeout of the work site.

Specifics of these expanded actions and procedures are discussed in the remainder of this Section.

3.4.1 Pit Excavations

Excavations at the disposal pits site began on July 14, 2009 with the preliminary excavation of material from Disposal Pits A and B located along the southern edge of the work area. Information developed during the ESI and the RI sampling and test pitting activities indicated that each disposal pit location was covered by a finite layer of "clean fill" or overburden soil above the buried debris. Furthermore, based on the ESI/RI geophysical characterization data of the burial pit sites, Pit A, B, and C2 appeared to have prominent, well-defined lateral limits, while the lateral characteristics of Pit C1 were less well defined. As such, the preliminary excavations at each pit focused on the stripping of thin lenses (3 to 6 inch cuts) of soil/fill from the top of the disposal pit location, followed immediately by the examination and radiological survey of the material excavated.

Radiological scanning was performed by the rad tech using an audio output 3-inch by 3-inch thallium-activated, sodium iodide (3"x3" NaI[Tl]) detector coupled to a digital rate meter. If the excavated material was free of radiation in excess of background levels and appeared to be free of debris, it was transported to, and staged in, the "Overburden" pile pending subsequent characterization and evaluation as potential backfill material at the excavation sites. The "Overburden" pile was located in the unlined open area to the north of Pits A and B, and to the east of Pits C2 and C1.

Once debris was observed or once scanning indicated radiation levels at or above background levels, the excavated material was transported to the material processing and staging area located west of the burial pit excavation sites for further handling and characterization. Excavation of material from each pit, and transport of excavated materials to the processing and staging area continued until visual evidence indicated that native soils or bedrock had been encountered along all excavation wall edges and the excavation floor. The excavation surrounding the deeper debris caches found at each excavation site was expanded laterally, as necessary, to assure that the open excavation was suitably sloped to prevent excavation wall collapse. Soil removal done to promote sidewall and slope stability resulted in the excavation of native soils from beyond the edge of the former burial pit debris cache locations and as such, this material was found to be free of debris and any evidence of radioactivity.

As such, this material was added to the "Overburden" stockpile, pending further chemical and radiological characterization to assess its possible reuse at the excavation sites as backfill.

Excavated material containing debris or indications of residual radioactivity moved to the materials processing and staging area next to Service Road No. 1 was laid out in 12–inch lifts (+/- 2-inches) so that it could be viewed, scanned by the rad tech with the 3"x3" NaI(Tl) detector, and surveyed to locate and recover intermingled debris, prior to further post-excavation processing and characterization. Additional details of the materials scanning, sorting, and separation procedures used are summarized below in **Section 3.4.3**.

The initial excavations of Burial Pits A and B were completed by mid-day on July 15, 2009. Excavation then began at the southern most portion of Pit C, in the area designated as Pit C2. Excavation of Pit C2 continued throughout the remainder of July 15th and throughout July 16th when the field crews demobilized for the weekend and the work site was secured. All mixed debris/fill materials recovered from the excavations at Pit A, B, and C2 were moved into the materials handling and staging area, and were segregated prior to scanning for radioactivity, and the recovery of military-related materials and other forms of debris. All recovered military-related items collected during the first week of work were turned over to and secured by the Army at the end of July 16th, as part of the end-of-week closeout process.

On July 20th, the field crew remobilized to the site, added the mechanical screening plant, and began the excavation of Pit C1. Field observations indicated that materials contained in Pit C1 were generally dissimilar to those found in the other three excavation pit sites; materials found in Pit C1 were found to contain C&D and miscellaneous debris whereas each of the other pits showed the presence of significant quantities of military-related items with levels of radioactivity at and slightly above background. The Pit C1 material was transported to the materials processing and staging area where it was laid out on plastic separately from the materials removed from Pits A, B, and C2. Excavation of Pit C1 was completed by the end of day on July 21st.

3.4.2 Preliminary Verification of Extent of Excavation

Subsequent to the completion of initial excavations from all burial pit locations, each pit was re-examined for signs of residual debris, soil staining, or discoloration in the exposed surfaces of the base, sidewalls, and within perimeter slopes of the excavation cuts. Furthermore, post-excavation radiological scans were performed at each excavation site to confirm the absence of elevated levels of residual radiation in any of the exposed surfaces. If debris, soil staining/discoloration, or evidence of radiation above background levels were observed/detected, they were further investigated and evaluated to determine their source and nature, and necessary actions (e.g., further excavations, hand-digging, etc.) were implemented to remove any identified debris or source material. Such material was added to the appropriate material processing stream, either in the materials processing and staging area or in the Army's secured location.

At the conclusion of the preliminary excavation of the disposal pits, approximately 1,037 cubic yards (cy) of material had been excavated from Pit A, approximately 286 cy of soil/debris had been

removed from Pit B, roughly 1,639 cy of material had been excavated from Pit C1, and approximately 1,436 cy of soil/debris had been excavated from Pit C2. Additional information (e.g., perimeter of deep excavation, perimeter of sloped excavation, total area, and maximum depth) pertinent to each of the excavation sites is summarized in **Table 3-1.** Details of the excavations are also displayed in **Figure 3-1**

3.4.3 Segregation of Debris

Once excavated materials were brought to the materials processing and staging area, they were laid out in 12-inch lifts on plastic, scanned for radiation, and identified radioactive materials, military-related items, and other debris were removed and segregated. The site rad tech conducted scanning using a Ludlum 44-20 which was operated in the audio response mode to identify locations with elevated readings, all of which were flagged for further investigation. Following the scan, field personnel returned to the flagged locations to investigate, identify, and remove the source of the noted radioactivity. If needed, the on-site construction equipment (e.g., dozer, excavator, etc.) was used to assist in the removal and recovery of any large object. Recovered radioactive materials were placed into B-25 waste containers for storage, pending further examination by Army personnel and storage/deposition determinations. Site laborers also removed other identified, non-radioactive debris from the soil lifts and placed these onto plastic for subsequent inspection and segregation determinations by Army personnel. Debris removed from the excavated material was either placed into B-25 boxes (radioactive), handed over to the Army for secure storage (other military-related items, electronic components, batteries, capacitors, etc.) pending dismantling, set aside as miscellaneous or C&D debris, or separated for potential recycle. Recovered metal debris that was not military-related or radioactive, was further segregated into piles of ferrous, aluminum, copper, and stainless steel scrap.

3.4.4 Mechanical Screening

In the secondary round of post-excavation material processing, excavated materials, exclusive of those separated and placed in the "Overburden" pile and those recovered during the lay down scanning and sorting operations described above, were run through a mechanical screening plant to separate the material into two size fractions (i.e., 6-inch plus and 6-inch minus). Material from the soil/debris lift areas was picked-up by a loader, and loaded into the screening plant's feed hopper. Processed excavated materials from Pit C1 were mechanically screened first, since they had been found to contain less radiation and military-related materials, and therefore posed less of a potential threat for cross-contaminating subsequent batches of materials mechanically screened. Processed, excavated material residuals from Pits C2, A, and B, where military-related items and radiation levels at or slightly above background were processed sequentially thereafter.

Oversized materials recovered from the mechanical screening operation were again laid out for review by Army representatives. Military-related items were recovered and secured by the Army and debris/materials (e.g., soil clods, debris, etc.) showing evidence of radiological activity were investigated and all recovered source materials were added to B-25 boxes. Other debris recovered from the oversized stream was segregated as necessary. The processed 6-inch minus stream from Pit

C1 was moved back into the processing and staging area where it was laid out on plastic again and rescanned manually for evidence of potential radioactivity before it was loaded into haul trucks and added to the "Overburden" pile.

During the processing of Pit C1 materials, a gamma detection system comprised of an array of three 3"x3" NaI(Tl) detectors connected to a Ludlum Model 4609-3 single channel analyzer was mobilized to the work site and installed immediately above the screening plant's conveyor belt discharge line to provide real-time scanning of soil and undersize material for residual radiation during the processing of excavated materials from Pits C2, A, and B. The detectors were suspended above and perpendicular to the direction of movement of the 24 inch discharge conveyor belt. Each detector was separated by a distance of approximately 6 inches, space outwardly from the centerline of the conveyor belt to provide maximum coverage of the discharge line. When the belt was loaded with soil, the distance between to the top of the soil and the bottom of a detector was approximately 3 to 4 inches, and a metal screen bar was placed across the conveyor belt upstream of the detector array to protect it from oversized clumps of soil/debris that might damage the detector or cause false positives. A laptop personal computer (PC) was used to monitor each detector's count rate, input parameters, and system alarms. Use of the PC allowed the system operator to closely observe its performance, and particularly to note the segment count when the system alarmed.

The maximum thickness of soil carried on the waste conveyor belt during processing was estimated by field operators as 3 inches thick. At the conveyor operating speed (i.e., 6 feet per second), each individual detector has a modeled minimum detectable concentration (MDC) of 3.0 picoCuries per gram (pCi/g) with no soil cover. Under a soil cover of 3 inches (the maximum observed soil thickness on the conveyor), the modeled MDC is 8.2 pCi/g. However, the intent of the detector system was to identify discrete sources that may have been missed during the previous scans, and to not assess low-level distributed activity in the soils.

In operation, when the detector system's alarm sounded, the screen plant was shut down, and suspect material on the conveyor was recovered, and this material was transported to a site where it could again be laid out on plastic in a thin lift for further manual scanning and sorting to identify the source. Many of the alarms proved to be "false-positives", but approximately one or two in ten resulted in the recovery of small fragments of radioactive materials (e.g., commonly radium dials or fragments), which were subsequently added to the B-25 box inventory. Once the undersize stream from Pits C2, A, and B was confirmed to be free of residual radioactivity in excess of background levels, it was transported to a location adjacent and parallel to the "jug-handle" turnaround area where it was staged in a windrow on plastic sheeting pending final chemical and radiological characterization, disposal determinations, and load out.

When Pit C2, A and B oversized materials were removed from the screening plant they were again scanned for residual radiation prior to being laid out for review by Army representatives. If radioactivity was noted, the oversized debris was added to the contents of a B-25 box pending further determinations by the Army. Other oversized debris was laid out on plastic for review by the Army

where final separation of military-related items from other forms of debris and recyclable materials occurred.

3.4.5 Suspension of Field Operations

On-site operations were suspended on August 13, 2009, upon completion of excavated material processing and mechanical screening, post-screening handling, segregation, and staging. Site work was suspended to provide time to receive and assess analytical results from confirmatory soil samples that were collected from all of the excavation pits, and from samples of materials contained in the "Overburden" and Pit C2, A, and B windrow. Confirmatory soil samples from the excavation sites were collected and submitted to contract laboratories for conventional target compound and target analyte list (TCL and TAL, respectively) constituents of concern only. Soil samples from the "Overburden" pile were collected and submitted for TCL, TAL and radiological analyses, while samples from the windrow comprised of Pit A, B, and C2 6-inch minus material were collected and submitted for waste characterization and radiological analyses. Additional information pertinent to the sampling and analysis of materials and the results obtained are provided in **Sections 3.4.6** and **3.5.1**, respectively, below.

Prior to suspending site operations, the field crew secured all of the excavation sites; covered all waste and material piles and containers; secured all radiological and military-related items in Building 814; and scanned all construction equipment for evidence of radiation and cleaned as necessary prior to releasing it from the work site. When work was suspended, the inventory of materials listed below remained at the site.

- Approximately 2,100 – 2,200 cy of excess 6-inch minus soil in the Overburden/C1 stockpile.
- Approximately 2,300 cy of mixed waste soil and debris from the 6-inch minus stream from Pit C2, A and B.
- Debris sorted into eight roll-offs, six B-25 boxes, and other covered piles.
    - Five roll-offs – Primarily aluminum metal.
    - One roll-off – Ferrous metals.
    - One roll-off – Mixed metals.
    - One roll-off – Trash and other debris.
    - Six B-25 Boxes – Military-related items with detectable levels of radionuclides – stored in secure location.
    - Other assorted debris and objects.

3.4.6 Sampling and Analysis

3.4.6.1 Conventional Chemical Analyses

Excavation Limit Confirmatory Sampling for Chemical Analysis

Subsequent to the completion of the initial excavations at the historic burial pits and before the temporary suspension of work activities, confirmatory soil sampling was performed to verify that conventional chemical hazardous substances (i.e., not radiological) were not present at levels in excess of acceptable levels. Confirmation sampling was done separately for chemical and radionuclides contaminants of concern (COCs and RCOCs, respectively), with the sampling and analysis of chemical COCs done first. Confirmatory sampling and analysis for RCOCs was conducted once the results for the chemical COCs were received, reviewed, and verified to comply with the desired cleanup levels.

Confirmatory soil samples from the base of the excavation were generally collected as a discrete grab sample from a unique location at a frequency of one sample per 2,500 square feet (sf) or less of excavation bottom, except in areas where the excavation extended to the bedrock surface and all soil was removed, in accordance with the FSP (Parsons, 2008a). At locations where the base of excavation was greater than 2 feet below the adjacent ground surface, sidewall samples were collected at a rate of one soil sample for every 50 linear feet (lf) or less. Sidewall samples were collected at a depth halfway between the base of the excavation and the adjacent ground surface or sloped bench elevation. Excavation perimeter samples were taken at locations approximately 1 to 2 feet back from the edge of the pit excavations, adjacent to the location of excavation pit sidewall samples. The minimum number of confirmatory samples required for each excavation is listed in **Table 3-1.** The approximate location of the initial confirmatory soil samples collected from four excavation pits (A, B, C1, and C2) are shown on **Figures 3-2** through **3-4**. The actual placement of the sample locations on the map has been moved from survey coordinate locations to enhance readability and understanding.

Field duplicates were collected to meet the quality assurance/quality control (QA/QC) requirements established in the Work Plan. The contract laboratories completed matrix spike (MS) and matrix spike duplicate (MSD) analyses on one site-specific project sample per sample delivery group (SDG). All samples were collected following procedures outlined in the Final Sampling Plan for Seneca Army Depot Activity (Parsons, 2008a).

Confirmatory soil samples for chemical COCs were submitted to a contract laboratory (primarily Columbia Analytical Services, Inc. [CAS], Rochester, NY; and subsequently Life Science Laboratories [LSL], East Syracuse, NY) for analysis total solids (EPA Method 160.3), TCL Volatile Organic Compounds (VOCs, EPA Method 8260B); TCL Semivolatile Organic Compounds (SVOCs, EPA Methods 3550C/8270C); TCL Pesticides (EPA Methods 3541/8081A), TCL Polychlorinated Biphenyls (PCBs, EPA Methods 3541/8082), and TAL Metals (EPA Method 6010B/7471A [Hg]) and cyanide (EPA Method 9012A). Life Sciences Laboratories was added to provide rapid

turnaround analyses during follow-up sampling and analysis that occurred once the field crews remobilized to the site for final operations.

Soil cleanup goals (CUGs) established by the Army for verification that no unacceptable levels of chemical COCs remained at the Burial Pit locations were defined as the State of New York's (NYS) Unrestricted Use Soil Cleanup Objective (SCO) levels as defined in Title 6, New York Code of Rules and Regulations (6NYCRR) Part 375-6.8(a).

Analytical data for conventional COCs are provided in **Appendix B**, **Tables B-1C** and **B-2**. The chain-of-custodies for the confirmatory samples are included in **Appendix E** and the case narratives for laboratory sample delivery groups are presented in **Appendix F**. All of the analytical results were validated in a manner that is consistent with EPA Region 2's Standard Operating Procedures (SOPs). Data validation reports for the conventional COCs are provided in **Appendix G**. Conventional chemical (TCL/TAL analytes) results obtained for the confirmatory soil samples are discussed in **Section 3.5** below.

Overburden/C1 Stockpile Analyses

Soil samples from the "Overburden/C1" stockpile were also collected and submitted to CAS Inc. for chemical analyses including total solids (EPA Method 160.3), TCL VOCs (EPA Method 8260B); TCL SVOCs (EPA Methods 3550C/8270C); TCL Pesticides (EPA Methods 3541/8081A), TCL PCBs (EPA Methods 3541/8082); and, TAL Metals (EPA Method 6010B/7471A [Hg]) and cyanide (EPA Method 9012A). Analytical results from the "Overburden/C1" samples were compared to the NYS Unrestricted Use SCO levels as defined in 6NYCRR Part 375-6.8(a).

Analytical data for conventional COCs are provided in **Appendix B**, **Table 3C**. The chain-of-custodies for the confirmatory samples are included in **Appendix E** and the case narratives for laboratory sample delivery groups are presented in **Appendix F**. All of the analytical results were validated in a manner that is consistent with USEPA Region 2's Standard Operating Procedures (SOPs). Data validation reports for the conventional COCs are provided in **Appendix G**. Conventional chemical (TCL/TAL analytes) results obtained for the confirmatory soil samples are discussed in **Section 3.5** below.

Six-inch Minus Cut Stockpile from Pits A, B, and C2

Samples of the six-inch minus waste soil cut from materials excavated from Pits A, B, and C2 were collected on August 6, 2009 and submitted to CAS Inc. for waste disposal characterizations. In accordance with the requirements and specifications identified by representatives of the Seneca Meadows Landfill, waste disposal samples for chemical COCs were collected at a frequency of one per every 700 cy of stockpiled waste material. Samples of the stockpile waste soil were also collected for radiological analyses at a frequency of one per every 200 cy as specified by the intended landfill recipient.

Prior to sampling, the volume of the six-inch minus waste soil windrow was estimated by surveying its extent and height using GPS. These survey coordinates were superimposed over previously defined site elevation survey data and the volume of the six-inch minus stockpile was estimated.

Waste characterization sample locations were then randomly sited across the length and width of the waste soil windrow, and samples for characterization of radiological and chemical waste characteristics were collected from sample depths varying from 2 inches to 2 feet below grade surface. As the material contained in the waste soil windrow was comprised of soil and fill that had been handled and mixed several times (i.e., excavated, moved to the laydown area, scanned, hand sorted, picked up for processing through mechanical screen, laid out and sorted again if mechanical screen radiation scanner alarmed, picked up, and staged pending analysis), these materials were considered to be well mixed within the windrow. Since the number of radiological samples required exceeded the number of samples needed for conventional waste characterization purposes per the requirements of the receiving landfill, the locations of the radiological samples were used as the primary sample locations and the necessary conventional waste characterization samples were collected from selected radiological sampling locations that scattered throughout the windrow.

All waste characterization analytical results obtained were reviewed by the Army, Parsons, and Cabrera Services upon receipt and once the data were found not to contain any unanticipated levels of chemical or radiological contamination, it was provided to representatives of Seneca Meadows Landfill for review and pre-approval prior to it being loaded onto trucks for transport to the off-site facility for disposal. None of the analytical determinations showed evidence of TSCA regulated materials or levels of radiation that were not within the landfill's permitted levels to receive.

Waste characterization samples collected for chemical COCs were analyzed by CAS Inc for toxicity characteristics (TCLP VOCs [Method 1311 Zero Headspace Extraction{ZHE} /SW-846 8260B], TCLP SVOCs [Method 1311 Extraction/SW-846 8270C] and TCLP Metals [1311 Extraction/SW-846 6010C and 7470]); total organochlorine pesticides/PCBs (pesticides [SW-846-8081A], PCBs [SW-846-8082]); ignitability (flashpoint [SW-846 1010]); corrosivity (pH [SW-846 9045D]); reactivity (reactive cyanide [SW-846 9014], and reactive sulfide [SW-846 9034 modified]); free liquid (SW-846 9095A), and total solids (EPA 160.3 modified).

Chemical COC results of these determinations are provided in **Appendix C**. The chain-of-custodies for the waste disposal characterization samples are included in **Appendix E** and the case narratives for laboratory sample delivery groups are presented in **Appendix F**.

Waste characterization samples collected for radiological COCs were analyzed by GEL Laboratories, LLC (GEL) of Charleston, South Carolina for gross alpha and gross beta by EPA Method 900.0M, and selected radionuclides of interest (see discussion in **Section 3.4.6.2**, below) using gamma spectroscopy by EPA Method 901.1M. Radiological COC results of these determinations are provided in **Appendix C**. The chain-of-custodies for the waste disposal characterization samples are included in **Appendix E**.

3.4.6.2 Radiological Analyses

Once analytical results for the conventional chemical COCs were received and reviewed, and once necessary re-digs were performed (see discussion in **Section 3.4.10**) and subsequent confirmatory

sample results for chemical COCs received, reviewed and approved, confirmatory scanning and sampling and analysis for radiological COCs (RCOCs) was performed.

Radionuclide Identification

Immediately after the discovery of the radioactive components in the burial pits, three samples of material and four smear samples exhibiting activity above background levels were sent to GEL in Charleston, South Carolina for quick screen gamma spectroscopy analyses. Results from these samples were used to confirm the RCOCs for this project. **Table 3-2** presents and summarizes the data obtained from these analyses. Summary discussions of the key results are provided below.

- S12DS01: This sample consisted of the material identified during the initial baseline scanning survey of the surface footprint of Pit C2. The location was flagged and excavated using shovels - the source material was found approximately six inches below the ground surface. Measurements returned to background levels following its removal.

  Based on the detection of radionuclides associated with both the naturally-occurring uranium and thorium decay series, the material is assumed to be unprocessed. One historical mission of SEDA was the storage of valuable ores, including pitchblende ore (in SEAD-48) and columbite ore. With the rock's location in the surface soil it is unlikely it was intentionally placed in the area for burial. No additional similar material was found over the course of the excavation and/or screening process.

- S12DS02: This sample was collected from the vicinity several items that had a large white-colored light metal sleeve with above-background radiation levels, and appears to be the same type of material. The results indicate the presence of natural thorium (Thorium-232 [^{232}Th]) progeny. The items themselves were not identified, but thorium alloys with aluminum, magnesium, and other light metals are common in aircraft parts and other components that must maintain structural integrity in high temperatures.

- S12DS03: This sample consisted of a clump of clay with small pieces of metal or paint, apparently from a damaged radium dial or gauge. The detection of three progeny of Radium-226 (^{226}Ra) without detections of uranium decay series progeny above ^{226}Ra, such as Thorium-234 (^{234}Th) confirm the presence of radium.

Based on these results, a Canberra Inspector 1000 portable multi-channel analyzer (MCA) was mobilized to the site to further assist in identification of the radionuclides present in components or debris excavated from the burial pits. The Inspector 1000 system consisted of a Lanthanum Bromide detector to allow for quick identification of detected gamma energies. Measurements were conducted on excavated debris using the manufacturer's recommendations. A Cesium-137 (^{137}Cs) source was used during the measurement to provide a reference energy (661 kiloelectron Volt [keV]) to determine potential spectral shift due to temperature or other fluctuations in operating parameters.

Radionuclides of Concern

Based on laboratory gamma spectroscopy results as well as the onsite screening with the MCA, the primary RCOCs for this project were identified as ^{226}Ra and ^{232}Th with progeny in equilibrium assumed.

Site Release Criteria

The radiological release criteria established by the Army for the Disposal Pits were as shown below.

1) The level of residual radioactivity distinguishable from background at this site would result in a total effective dose equivalent (TEDE) to an average member of the critical group of 10 millirem per year (mrem/yr) or less as per NYSDEC standards (NYSDEC, 1993); and

2) The level of residual radioactivity represents an excess lifetime risk of cancer, at a point of exposure, to an average individual no greater than between 10^{-4} and 10^{-6}.

The Nuclear Regulatory Commission (NRC) applies a TEDE standard of 25 mrem/yr; the USEPA recommends a TEDE standard of 15 mrem/yr; for this site, a TEDE of 10 mrem/yr (a more restrictive criterion) based on the New York's Technical and Administrative Guidance Memorandum (TAGM) 4003 (NYSDEC, 1993) guide was selected.

Levels of residual radioactivity that correspond to the allowable radiation dose are calculated by analysis of various scenarios and pathways through which exposures could be reasonably expected to occur. The *Summary of Field Activities* (Cabrera, 2009) specified derived concentration guideline levels, or DCGLs, which are the concentration of residual radioactivity distinguishable from background that, if uniformly distributed throughout a survey unit, would result in a TEDE to an average member of a critical group equivalent to the allowable dose. These wide-area DCGLs were developed by Argonne National Laboratory (ANL) for use during the license termination effort at SEDA in 2003. These dose-based criteria did not properly account for the residual risk due to residual radioactivity above background at the site. Therefore, for the purposes of satisfying both dose- and risk-based criteria, the data from this survey of the final surfaces of the pits was included as the source term in site-specific dose and risk assessment using the computer code developed by ANL, *Residual Radioactivity (RESRAD), Version 6.5*.

Identification of Impacted Areas

Three impacted areas were identified during confirmation surveys (Pits A/B, Pit C1, and C2). Confirmation surveys of the final surfaces of these pits were based on MARSSIM guidance. Each pit was evaluated as a Class 1 survey unit [SU] in a fashion similar to a standard MARSSIM final status survey, except for a few key differences, which are described in **Section 3.5**. Burial pit sizes are provided in **Table 3-1**.

Background Reference Area

Background concentrations of ^{226}Ra and ^{232}Th and other naturally-occurring radionuclides were determined using the surface and subsurface data set collected during the SEAD-63 project conducted in 2004 (Plexus, 2005). Unlike SEAD-12, no radioactive items were discovered during the SEAD-63

excavation support. Gamma spectroscopy data for Actinium-228 (^{228}Ac), Bismuth-214 (^{214}Bi), Potassium-40 (^{40}K), and ^{234}Th, as well as gross alpha and beta results, were evaluated for statistical outliers and no anomalous data were identified. Therefore, the soils at SEAD-63 were considered unimpacted from a radiological perspective and these results were used as a background dataset for the Disposal Pit removal action. The summary statistics of the evaluated radionuclides are presented in **Table 3-3**.

Survey Design

The MARSSIM guidelines for sampling design for a Final Status Survey (FSS) were followed in determining the appropriate number of samples to be collected. The initial step is the determination of the relative shift using the following equation:

$$\text{Relative Shift} = \frac{\Delta}{\sigma} = \frac{DCGLw - LBGR}{\sigma}$$

Using the background data for ^{214}Bi and ^{228}Ac shown in Table 3-2, a combined σ was calculated to be 0.16 pCi/g. Using the sum of ratios and unity rule, the $DCGL_W$ is unity, and the lower bound of the grey region is set to 0.5 as a default value. A relative shift of 3.1 results, and from that relative shift, the random measurement probability (P_r) is determined to be 0.983039 from MARSSIM Table 5.2.

The following equation (MARSSIM Equation 5-1) was then used to determine the total number of samples in the survey unit/reference area pair:

$$N = \frac{\left(Z_{1-\alpha} + Z_{1-\beta}\right)^2}{3\left(P_r - 0.5\right)^2}$$

The terms $Z_{1-\alpha}$ and $Z_{1-\beta}$ both reflect the desired Type I and II error rates, both set at 0.05. The total number of samples was then divided by two and increased by a factor of 20%, per MARSSIM recommendations. The overall number of samples required per survey unit was calculated to be 10 samples.

The appropriate number of systematic samples within the pits was calculated to be 10 per 2000 square meters (m^2) Class 1 survey unit, or approximately 1.1 per 2500 square feet (ft^2). This frequency was met by utilizing the sampling points from the chemical sampling activity, which were collected at a frequency of at least 1 sample per 2500 ft^2 from the excavation floor and sidewalls. A grid of the pit areas consisting of 50 ft X 50 ft squares was established prior to the excavation activities and was used to guide sampling frequency. The grid is shown in **Figure 3-1**. A sample was also collected every 50 linear feet along the perimeter of each of the pits to ensure that area immediately surrounding each of the burial pits was not impacted by remedial activities.

Because of the nature of this remediation, these samples were co-located with chemical sampling locations on the basis of a square sampling grid in accordance with the *Radiological FSP* (Parsons, 2009) and the *Summary of Field Activities* (Cabrera, 2009). While the sample density was calculated in accordance with MARSSIM guidelines, the sample locations were not pre-selected based on a

systematic triangular grid as is advised in MARSSIM. Biased samples were collected based on gamma walkover survey (GWS) results as is described below.

Integrated Survey Strategy

Confirmation surveys of open land areas consisted of performing GWS to identify locations of residual contamination and collecting soil samples to be analyzed for the project RCOCs. Additional biased measurements and samples were obtained, as necessary, from locations where scans indicated the potential for residual contamination.

GWS was performed using a Ludlum Model 44-20 three inch by three inch sodium iodide (3x3 NaI) detector coupled to a Ludlum Model 2221 ratemeter. This detector was linked to a GPS receiver/datalogger so that activity measurements could be spatially referenced. Scanning was performed in accordance with MARSSIM protocol by walking straight parallel lines with the detector approximately 10 centimeters (cm) above the ground surface. Survey passes were approximately 0.5 m apart and the scan rate was approximately 0.5 m per second.

Data collected during surface gamma scans in the burial pits was recorded every second along with corresponding easting and northing GPS coordinates. The measurements were plotted and color-coded for visual review and evaluation with the coordinates of the highest measurement identified for possible biased sampling. The average and standard deviation were calculated for each SU to allow evaluation of the data outliers via Z-score. Z-scores represent the number of standard deviations the result lies from the mean, based on following formula:

$$Z - score = \frac{CountRate - Mean}{StdDeviation}$$

All areas exceeding three standard deviations above the average (i.e., Z-score greater than or equal to 3.0), were flagged for further investigation. A biased sample was collected at the location with the maximum Z-score in each burial pit.

Surface soil samples were also collected from burial pit surfaces at locations co-located with chemical sampling locations on a square sampling grid as described in **Section 3.5**. Following collection, soil samples were maintained under formal chain-of-custody procedures, sent to the offsite laboratory, and analyzed by gamma spectroscopy, with analytical results reported in units of pCi/g. At least 11 samples were collected in each SU.

All samples collected for radiological COC characterization were submitted to GEL Laboratories, LLC in Charleston, South Carolina and analyzed for gross alpha and gross beta by EPA 900.0/SW846 9310/SM 7110B Modified and selected radionuclides by EPA 901.1 Modified.

Raw analytical results from GEL are provided in **Appendix B**. Processed Final Status Survey results are provided in **Appendix D**. The chain of custodies for the confirmatory samples are included in **Appendix E**.

3.4.7 Remobilization to the Work Site

Subsequent to the receipt and assessment of the analytical results from the conventional chemical confirmatory soil samples, field crews and equipment were remobilized to the Burial Pits site to complete the removal and recovery of military-related items and other forms of debris. Field activities recommenced at the site on September 29, 2009 and work subsequently conducted included further excavation and processing of additional soil/debris from locations around three of the excavation pits (A, B, and C2); the load-out and disposal of waste and recycled materials from the work site; the performance of radiological scans at all completed excavation sites; the collection and analysis of confirmatory samples for radiological constituents of concern; geophysical surveys of all work areas and travel/haul roads using metal detectors (i.e., Schonstedts and EM-31) to locate and remove ("mag and dig") metallic debris objects that had fallen to and become buried in disturbed soils during excavation, loading, hauling, material processing and handling operations; the backfill or regrading of the excavation pit sites; disturbed area landscaping and seeding; and the final demobilization of all field equipment and personnel.

3.4.8 Additional Geophysical Surveys

The Army initially requested that the field crews perform additional visual and geophysical surveys of all of the excavation impacted areas (e.g., excavation area side perimeters areas, travel/haul roads, material handling and staging area, etc.) as part of site cleanup and restoration activities. As a first step in this process, Parsons mobilized a two man "mag + dig" team to the site, and these personnel conducted walkover surveys of all affected areas using a Schonstedt metal detector to locate debris that had fallen from construction equipment as it was excavated, loaded, transported, and processed around the excavation sites, the haul roads, and in the materials handling and staging areas. Each item identified during this process was subsequently recovered and reviewed by site personnel in accordance with established procedures (i.e., scanned for radiation; laid out for Army inspection; added to secured material, material to be recycled, or general debris stream for final disposition; etc.). Subsequent to the discovery of a large debris cache exterior to the original Pit C2 excavation (see discussion in **Section 3.4.10**), the Army requested that site geophysical surveys be expanded to include EM-31 surveys around each of the open excavation sites. Initially, the EM-31 surveys were limited to the excavation sites and a buffer zone that extended 25 - 35 laterally outwards from all of the excavation disturbed areas around each of the open pits. The EM-31 survey area was subsequently expanded to encompass all of the larger open area that defined the suspected location of the Burial Pits site (i.e., bounded by northern and eastern perimeter security fence of the WSA, by the southern wooded area, and by the north-south oriented row of trees that separated the suspected burial pit area from the material processing and staging area). Results of the area-wide EM survey that was completed by October 15th are provided in **Figure 3-5**, and this figure shows evidence of buried debris in the vicinity of Pit C2 and Pit A.

The final EM-31 survey was conducted along parallel survey lines that were spaced at 10-foot intervals throughout the open area. Monitoring well installations located in close proximity to the open excavations blinded the EM-31 survey equipment due to the presence on metal in the

construction, and limited the field crew's ability to make firm determinations as to the possible continuing presence of debris and other materials around these installations. To eliminate this interference, each of these wells was dug out by the excavator, and all well components were removed (see discussion in **Section 3.4.9**, below). EM-31 surveys then were re-performed around the locations of the excavated well installations and these data were used to confirm the absence of buried debris and objects in these areas. Results of the EM-31 survey were used to locate areas where expansions to pit excavations were required (i.e., Pit C2) and localized re-digs of spot items were needed. Final EM survey results reported on October 30, 2009 for the SEAD-12 work area are shown in **Figure 3-6**.

3.4.9 Monitoring Well Removal

Monitoring wells MW-12-7, MW12-8, MW12-10, MW12-11, MW12-12, MW12-13, MW12-14, MW12-15, MW12-33, and MW12-34, each of which is located in close proximity to one of the burial pit (i.e., Pits A, B, C1, or C2) sites, were excavated and removed in their entirety to eliminate the geophysical survey equipment blinding issues described above. All excavations made to remove the identified wells extended over the full depth of the overburden soil/fill that lay above competent bedrock in this portion of the SEAD-12 site. During the excavation and removal of each of the targeted wells, all installation components (i.e., sand pack, grout, well screen and upriser, protective cover, well collar, etc.) and surrounding native soils were removed and all excavated materials and debris were either disposed at the Seneca Meadows Landfill as soil cover material or C&D debris, or sent to the recycler as scrap metals (e.g., protective metal casing) once they were removed. Since each of the excavated well installations was located immediately adjacent to the larger open excavations where military-related items and other forms of debris had been recovered, the Army did not believe that the abandonment of the identified wells in this manner would result in the development of any higher level of preferential flow path between the surface and the underlying bedrock regime than the open excavation already represented. As such, once each well was excavated, removed, and the surrounding and underlying areas were cleared via EM survey, each of the former well locations was abandoned and backfilled in a manner equivalent to those used at the larger excavation pit sites. In the case of well installations in proximity to Pits A and B, each of the former wells were backfilled using soil from the "Overburden/C1" stockpile that was dumped and pushed into the open holes using bulldozers. At well location near Pits C1 and C2, the bulldozers pushed native soils that surrounded the open excavation sites back into the open holes and graded the areas to promote positive drainage away from the sites. Soil and fill used to backfill all of the excavations was compacted, prior to final grade, raking and re-seeding to establish a vegetative cover.

3.4.10 Additional Burial Pit Excavations

Additional excavations were conducted along the northern face of excavation Pit B, in a larger area around Pit C2, and at an isolated debris cache located to the south of Pit A. Details of this additional excavation work is provided below.

Additional Pit B Excavations

Two subsequent sequences of excavation and confirmatory sampling and analysis for conventional COCs were performed along the northern face of Pit B during early October 2009 (i.e., October 1 and October 8). Each of these excavations removed a three- to five-foot slice of soil along the entire length of and depth of the Pit B's northern excavation face. These excavations were initiated as a result of the review of confirmatory soil data that showed that there were levels of aroclor-1254 in excess of NYSDEC's Unrestricted Use SCO (100 μg/Kg) in the sidewall and perimeter samples collected from locations S12EXSW-O-8-01 and S12EXPR-O-8-01 (see **Figure 3-2**). Once the initial redig at Pit B was completed, confirmatory samples S12EXSW-O-8-14 and S12EXPR-O-8-14 were collected and submitted for rapid turnaround time analysis of polychlorinated biphenyls. When results for both of these replacement samples were received and reviewed, they again showed elevated levels of aroclor-1254, so a second sequence of excavation followed by the repeat collection and analysis of replacement sidewall and perimeter samples (i.e., S12EXSW-O-8-05 and S12EXPR-O-8-05) from this face of the pit's excavation face. The results of the reanalysis of samples for PCBs showed acceptable levels of aroclor-1254, and all other PCB congeners after the second redig at Pit B.

Materials removed during these subsequent excavations at Pit B were again moved to the material handling and processing area where they were laid out, scanned for evidence of radiation in excess of background levels, and surveyed for evidence of intermingled military-related items or other forms of debris. Military-related items and other debris were not noted in these soils, and no elevated levels of radiation were associated with any of this soil based on real-time scanning performed.

Pit C2 Excavations

As part of the initial "mag +dig" surveys, the survey team identified a large metal anomaly beneath the surface of the ground to the northeast of Pit C2 (in grid cell J3). When this anomaly was investigated, a large metal object was uncovered, which subsequently was removed using the excavator (due to its size). During this removal operation, a larger cache of buried debris was uncovered beneath the initial object and as a result, a satellite excavation extending into grids I3, I4, J3 and J4 (including benching) was created adjacent to Pit C2 from which approximately 70 cy of material was excavated, and transported to the materials handling and processing area, where it was laid out on plastic, scanned and processed to remove all radiological items, identified military-related items, and other forms of miscellaneous debris. Once all debris and items of interest were recovered and secured, the waste soil was staged for subsequent disposal at the off-site landfill.

Once the EM-31 surveys were performed around Pit C2, additional buried objects were identified in previously unexcavated areas immediately surrounding Pit C2 (in grid cells I2 and J2), at other locations between Pit C1 and C2, and to the south-southeast of Pit A. **Figure 3-5** presents the results of the EM-31 surveys conducted after the initial excavations at each of these were cleared and samples were collected. Each of the identified areas showing an EM-31 response suggesting buried objects were subsequently investigated by field crews. Investigation of anomalies identified in grid cells I2 and J2 resulted in the excavation of another 300 cy of material from grid cells G2, H2, I2, J2,

K2, G3, H3, I3, H4, I4, and J4 (including stability benching, see **Figure 3-7**), all of which was transported to the materials handling and processing area where it was laid out on plastic, scanned for evidence of radiation, manually sorted, debris and soil separated, recovered debris presented for inspection by Army personnel, and then segregated as either radiological materials (secured in B-25 boxes), military-related items secured by the Army, or added to the recycle, C&D/miscellaneous debris stream, or added to a soil stockpile for load out to the local off-site landfill. Additional excavations around Pit C2 took place during the period from October 5 to October 13, 2009. Confirmatory sampling and analysis for COCs and RCOCs were performed in the expanded pit area on October 5, October 7, and October 15, 2009. The extent of the additional excavation in Pit C2 can be seen in **Figure 3-7**.

Pit A Excavation

When the anomaly to the south-southeast of Pit A was excavated, it was found to be surficial in nature and to contain only C&D debris (fence posts, concrete, and chain link fence), which was added to the C+D waste debris stream.

3.4.11 Final Verification of Extent of Excavation

At the conclusion of the excavation of the pits, approximately 1,037 cy of material had been excavated from Pit A, approximately 349 cy of soil/debris had been removed from Pit B, roughly 1,639 cy of material had been excavated from Pit C1, and approximately 2,376 cy of soil/debris had been excavated from Pit C2. Additional information (e.g., perimeter of deep excavation, perimeter of sloped excavation, total area, and maximum depth) pertinent to each of the excavation sites is summarized in **Table 3-1**. Details of the excavations are also displayed in **Figure 3-6**. The locations of all of the final confirmatory soil samples are shown on **Figure 3-8** through **3-10**.

3.4.12 Load-Out of Waste Soil and Debris and Recycle Materials

Military–related items

Military-related items and debris recovered from the excavation sites included non-radioactive and radioactive materials. Recovered, non-radioactive military-related items were disfigured or dismantled prior to being added to waste streams going to the landfill as C&D or added to the recycle stream that was sold and shipped off-site to a metal recycler for subsequent reclamation (see discussion below). Military-related items that were found to be radioactive were disposed by the Army as low-level radioactive waste at Energy Solutions LLC in Utah.

Waste Soil and C&D and other Miscellaneous Debris

Concurrent to the excavation and removal of additional soil from the northern face of Pit B, the field crews began the load out of waste soil from burial pit excavations A, B, and C2 that had been staged along the western edge of the materials processing and staging area adjacent to the "jug handle" truck turnaround. Results from the disposal characterization samples for conventional and radiological COCs were provided to personnel of Seneca Meadows Landfill for review and approval. Based on their review of the data provided, the landfill approved the six-inch minus cut from burial pit

locations A, B and C for disposal as cover material and authorized the Army to proceed with the transport of this material to the landfill site. Miscellaneous debris and C&D debris were also accepted for disposal within the landfill.

Load out of the original six-inch minus waste soil windrow began on September 30, 2009 and was initially completed by October 2, 2009. Additional soil and debris was loaded out thereafter as needed based on the excavation and processing of additional soil and debris from Pits A, B, and C2. All soil and debris was removed by October 29, 2009. Parsons subcontracted with Riccelli Enterprises, Inc. to transport and dispose of the excavated non-hazardous soil cover material, C&D Debris, and miscellaneous debris at the Seneca Meadows Landfill. At the completion of the removal action, more than 5,420 tons of cover soil and debris was transported to, and disposed at, Seneca Meadows Landfill. Information pertinent to the load out and shipment of soil and debris to the Seneca Meadows Landfill is provided in **Appendix J**.

Recyclable Materials

Compliance with the EPA Region II "Clean and Green" policy was demonstrated through the recycling of materials. Riccelli Enterprises, Inc. also transported recyclable metals that were removed from the SEAD-12 burial pit locations to Luffman Metal Recyclers in Seneca Falls New York. Scrap metal excavated from the site were segregated into varying categories of waste metals (e.g., aluminum, stainless, ferrous, copper, etc.) and were loaded into roll-off containers which were then transported to Luffman's. By the end of the work, more than 122 tons of mixed metal scrap was sent to Luffman's for recycle. Information pertinent to the recycle of metal to the Luffman Metal Recyclers in Seneca Falls NY is also provided in **Appendix J**.

3.4.13 Water Removal

Approximately 17,000 gallons of water was recovered from the disposal pit excavations over the duration of the removal action. This water was pumped from the excavation sites into a Bakers tank, where it was mixed with approximately 50 gallons of wastewater generated at Building 803 as part of the RCRA Closure activity performed at this location during July 2009. One water sample was collected and submitted to Columbia Analytical Service, Inc for determination of TAL and TCL analytes (metals, VOCs, SVOCs, pesticides and PCBs). The analytical data for sample WW1006-1 was submitted to the Seneca County Water/Sewer District for their approval. Approximately 17,000 gallons of water were discharged to the Sewer District. The complete analytical results for the water samples are included as **Appendix K**.

3.4.14 Site Restoration

No off-site borrow material was used to backfill or regrade the disposal pits. Pits A and B and associated monitoring well locations were backfilled using soil from the "Overburden/C1" stockpile. Analytical results for these soils are discussed in **Section 3.5.1** Overburden / C1 Stockpile discussion, below. Excavations at Pits C1 and C2, and monitoring well locations associated with these pits were backfilled by pushing native soil from high areas surrounding the excavation areas back into the excavation locations and grading to promote positive drainage away from the sites. During the

backfill and regarding operations, the temporary silt fence located to the east, north, and northwest of the Overburden/C1 stockpile was removed and disposed at the licensed landfill. Additionally, excavation site stabilization benches, temporary soil berms, and storm water diversion swales created around each of the excavation pit sites were also regraded to promote positive flow throughout the former work areas.

Once all of the excavation sites were backfilled and graded, all areas were raked and seeded on November 2 and 3, 2009 with winter wheat to promote vegetation and to prevent erosion.

The erosion and run-off controls established between the work/support/laydown areas and the wooded area and creek to the south and the drainage ditches to the west along Service Road No. 1 were left in place, pending the revegetation of the work/support area sites.

3.5 ANALYTICAL RESULTS

3.5.1 Conventional Chemical Analyses

Confirmatory Soil Sampling Results

Pit A

Thirteen (13) confirmatory soil samples, including three floor, five sidewall, and five perimeter samples were collected from Pit A after the completion of the initial excavation in July 2009. Summary results for these samples are provided in **Table 3-6**. The full data set for these samples is provided in **Appendix B**. The location of the final confirmatory soil samples is shown in **Figure 3-8**.

Thirty-one contaminants of potential concern (COPCs) were identified in one or more of the 13 confirmatory samples collected from Pit A, including eight VOCs, one SVOC, one PCB, one organochlorine pesticide, and 20 metals. Of the 31 COPCs identified, only two metals, chromium (1 time) and nickel (7 times) were observed at concentrations that exceeded NYSDEC's Unrestricted Use SCO levels. The range of concentrations observed for chromium in soil ranged from a minimum of 15.1 milligrams per Kilogram (mg/Kg) to a maximum of 46.7 mg/Kg, with a mean of 20.1 mg/Kg and a 95th percentile upper confidence limit (95th UCL) of the arithmetic mean of 24.5 mg/Kg, which is below the NYSDEC Unrestricted Use SCO for chromium of 30 mg/Kg. The range of concentrations noted for nickel in the Pit A soil samples varied from a minimum of 25.4 mg/Kg to a maximum of 39.6 mg/Kg, with a mean concentration of 31.2 mg/Kg and a 95th UCL value of 33.65 mg/Kg. The NYSDEC Unrestricted Use SCO for nickel is 30 mg/Kg. Comparison of the mean and 95th UCL nickel values in the remaining Pit A soils are generally consistent with the nickel values found in Seneca specific background samples.

Based on the limited number of compounds (i.e., two) that were detected at concentrations above their respective Unrestricted Use SCO levels, and the fact that while nickel was detected more than once at a concentration above its SCO the 95th UCL concentration found for all confirmatory samples from this pit was 33.7 mg/Kg which is generally consistent with the Seneca background concentration for nickel in soil, the Army determined that no further excavations were required at Pit A.

Pit B

Ten (10) confirmatory samples, including one floor, four sidewall, and five perimeter (four samples and a duplicate) were originally collected from Pit B.

Twenty-four (24) COPCs were detected in one or more confirmatory samples characterized from Pit B, including two VOCs, one PCB, two organochlorine pesticide, and three metals. Of these 24 COPCs identified, one PCB (Aroclor-1254 – 2 times), two organochlorine pesticides (4,4'-DDE – 2 times; 4,4'-DDT – 1 time), and one metal (nickel – 3 times) were observed at concentrations that exceeded NYS's Unrestricted Use SCO levels. Of further note was that all of the observed exceedances for the PCB and the organochlorine pesticides, and one of the exceedances for nickel were collocated in two samples collected from the sidewall and perimeter on the north face of Pit B. Based on this observation, additional excavation was performed along this pit face once the field crew returned to the burial pit sites to remove the contaminated soil.

Confirmatory results from the first subsequent excavation at Pit B continued to show evidence of aroclor-1254 at concentrations in excess of the State's Unrestricted Use SCO in both the sidewall and perimeter samples (S12EXSW-O-8-14 and S12EXPR-O-8-14, respectively), so this process was repeated a second time. Confirmatory data from the second additional excavation sequence (samples S12EXSW-O-8-05 and S12EXPR-O-8-05, respectively) showed that the aroclor-1254 were not detected at concentrations in excess of NYSDEC's Unrestricted Use SCO levels.

At the conclusion of excavations at Pit B only 22 COPCs were found in the final confirmatory samples collected from Pit B, and of these COPCs the only contaminant that was observed to be present at concentrations in excess of its NYSDEC Unrestricted Use SCO goal was nickel. The range of concentrations noted for nickel in the Pit B varied from a minimum of 20.9 mg/Kg to a maximum of 34.9 mg/Kg, with a mean concentration of 27.7 mg/Kg and a 95th UCL value of 30.1 mg/Kg. The NYSDEC Unrestricted Use SCO for nickel is 30 mg/Kg. In comparison the mean and 95th UCL nickel values in the Pit B soils are slightly lower than those found in Seneca specific background samples.

Based on the findings that nickel was the only compound observed to exceed NYSDEC Unrestricted Use SCO levels, and that this occurred in fewer than half of the confirmatory soil samples collected, and that the 95th UCL calculated for all of the final data at the site showed close agreement with the Unrestricted Use SCO (30.12 mg/Kg versus 30 mg/Kg) the Army determined that no further excavations were required at Pit B.

Summary results for the final samples collected from Pit B are provided in **Table 3-7**. The full data set for these samples is provided in **Appendix B**, **Table 1C**. Analytical results for the samples that were excavated are provided in **Appendix B**, **Table 2**. The location of the final confirmatory soil samples is shown in **Figure 3-8**.

Pit C1

Twenty-one (21) confirmatory samples were originally collected from Pit C1; these included three floor samples, nine sidewall samples (eight samples and a duplicate), and nine perimeter samples

(eight samples and a duplicate). Summary analytical results for these samples are provided in **Table 3-8**. The full data set for samples collected from Pit C1 is provided in **Appendix B**, **Table 1C**. The location of the final confirmatory soil samples is shown on **Figure 3-9**.

Thirty-four (34) COPCs were detected in one or more confirmatory samples collected from Pit C1, including six VOCs, five SVOCs, three organochlorine pesticide, and 20 metals. Of these 34 COPCs, three organochlorine pesticides (4,4'-DDD – 1 time, 4,4'-DDE 2 times; and 4,4'-DDT – 2 times), and five metals (chromium, copper, manganese and zinc – 1 time each; and nickel – 8 times) were detected at concentrations that exceeded their respective NYSDEC Unrestricted Use SCO levels. Estimated 95th UCLs for four of the metals (i.e., chromium, copper, manganese, and zinc) computed for Pit C1 data were all lower than their respective NYSDEC Unrestricted Use SCO values. The estimated 95th UCL for nickel (i.e., 35.1 mg/Kg) was higher than its NYSDEC SCO value (i.e., 30 mg/Kg) but generally consistent with the 95th UCL computed for nickel in background soils at Seneca (34 mg/Kg). With reference to the organochlorine pesticide species, all five detections and noted exceedances were collocated in two separate perimeter samples collected from the southern end of the overall excavation.

Based on the determination that nickel was the only compound observed to exceed its NYSDEC Unrestricted Use SCO level in more than 10 percent of the samples collected, and that this occurred in fewer than half of the confirmatory soil samples collected, and that the 95th UCL calculated for all of the final data at the excavation was generally consistent with background concentrations for nickel at the Depot, the Army determined that no further excavations were required at Pit C1.

Pit C2

At the conclusion of excavations at Pit C2, 43 confirmatory soil samples were collected and analyzed for conventional chemical COCs. These included eight floor samples (six samples and two duplicates), 15 perimeter samples, and 20 sidewall samples (19 samples and a duplicate). Excavation floor samples were not collected in grid cells I2 and J3 because the excavations in these areas extended to bedrock. Paired sidewall and perimeter samples were not collected at locations S12EXSW-J-2-02 and S12EXSW-I-3-04 due to the gentle slope of the excavations that were present at these locations. A perimeter sample was not collected from grid cell I-2-03 where a sidewall sample (i.e., S12EXSW-I-2-03) was collected from a limited excavation that was opened to remove a cache of debris that was identified during geophysical surveys conducted as part of the final removal action verification activities. Summary analytical results for these samples are provided in **Table 3-9**. The full data set for these samples is provided in **Appendix B**, **Table 1C**. Analytical results for the samples that were excavated are provided in **Appendix B**, **Table 2**. The approximate location of the final confirmatory soil samples is shown in **Figure 3-10**. The actual placement of sample locations on the map has been moved from survey coordinate locations to enhance readability and understanding.

Thirty-eight (38) COPCs were detected in one or more confirmatory samples collected from Pit C2, including nine VOCs, three SVOCs, one PCB, five organochlorine pesticides, and 20 metals. Of these 38 COPCs, only three metals and three pesticides were detected at concentrations in excess of

NYS Unrestricted Use SCO values in any samples. Nickel (15 times) and manganese and zinc (1 time, each) were the three metals detected at concentrations that exceeded their respective NYSDEC Unrestricted Use SCO levels. The single exceedance for manganese was found at a level of 1630 mg/Kg, and was found in sample S12EXPR-I-2-02. The estimated 95th UCL for manganese for samples from Pit C2 was 557 mg/Kg, which is well below NYSDEC's Unrestricted Use SCO value of 1,600 mg/Kg. The single exceedance for zinc was found at a level of 118 mg/Kg, and was found in sample S12EXSW-J-4-01. The estimated 95th UCL for zinc for samples from Pit C2 was 60.2 mg/Kg, which is well below NYSDEC's Unrestricted Use SCO value of 109 mg/Kg. Sample concentrations reported for nickel in samples from Pit C2 ranged from a minimum of 11 mg/Kg to a maximum of 48 mg/Kg, with a mean value of 29.2 mg/Kg and an estimated 95th UCL level of 30.8 mg/Kg, which is just above the NYS Unrestricted Use SCO of 30 mg/Kg, and slightly lower than the level of nickel found in background soils at the Depot.

With reference to the three pesticides, alpha-BHC was detected in four samples and two of these samples contained concentrations that exceeded its NYSDEC Unrestricted Use SCO value of 20 µg/Kg. Beta-BHC was detected in one sample, at a level of 63 µg/Kg which exceeds its NYS Unrestricted Use SCO of 36 µg/Kg. Comparably, delta-BHC was detected in three samples with one concentration measured at a maximum of 61 µg/L as compared to its Unrestricted Use SCO value of 40 µg/Kg. Based on the assessment of this data, excavations were determined to be complete at Pit C2.

Overburden / C1 Stockpile

Concurrent to the collection of confirmatory samples from the historic disposal pit excavation sites, samples of soil from the stockpile containing stripped overburden and the sub 6-inch cut of processed soil from the Burial Pit C1 excavation were collected and submitted to the laboratory for chemical analysis. All of these samples were submitted to CAS Inc. in Rochester NY and each of these samples was characterized for the same list of analytes as were characterized in the confirmatory samples collected from the excavation sites (discussed above). Prior to the collection of samples from the stockpile, a GPS survey of the stockpile was performed and the approximate volume of overburden/C1 material contained in the windrow was estimated to be 2,200 – 2,400 cy. Samples for characterization were collected at a rate of one per every 200 cy of soil (or less). The full analytical data for conventional COCs are provided in **Appendix B**, **Table 3C**.

Twelve soil samples were collected and analyzed from the Overburden/C1 stockpile after the completion of the preliminary excavations at the historic burial pit sites. Summary analytical results for these samples are provided in **Table 3-10**. Thirty-four contaminants of potential concern (COPCs) were detected in one or more of the collected samples C2, including three VOCs, 11 SVOCs, one PCB, and 19 metals. Of the 34 COPCs identified, only nickel (5 times) was ever detected at concentrations in excess of its NYSDEC Unrestricted Use SCO level (30 mg/Kg). The maximum detection observed for nickel was at a level of 32.3 mg/Kg. The estimated 95th UCL for nickel for samples from the overburden/C1 stockpile was 30.5 mg/Kg, which is only slightly above

the NYSDEC's Unrestricted Use SCO value. Based on the assessment of the data, the Army determined that the "Overburden/C1" stockpile was suitable for use as backfill at the sites.

3.5.2 Radiological Survey Results

A summary of the Radiological Survey results are presented below. Complete analytical data are provided in **Appendix B**, **Table 3R**. A full discussion of the Radiological Survey process for radiological contaminants of concern is provided in **Appendix D.**

The impacted areas of SEAD-12 consist of Pits A/B and Pits C1 and C2. Pit C1 and C2 results were combined into one data set (Pit C) to maintain consistency with the Risk Assessment that was performed at SEAD-12 in 2000. Ten samples were collected from clean overburden material overlying the actual burial pit locations. These clean overburden soils/fill were excavated from the top 2.5 feet at Pit A and B, the top 0.5 feet at Pit C Area 1 north, and the top 3 feet at Pit C Area 2 south and set aside for temporary staging (Parsons, 2009). Because these soils were intermixed during the backfill and restoration and used to backfill Pit A/B, the overburden sample results were added to the Pit A/B evaluation to represent the current condition of the backfilled pit.

Confirmation survey soil sample data from 2009 was combined with previous SEAD-12 radiological sample data from the original baseline risk assessment (BRA) to develop an updated risk/dose model for the site. A detailed description of this assessment is provided in **Section 7.0**. Analytical data for the BRA are included in **Appendix D**, **Attachment C**.

Systematic soil sample summary results for the pit surveys are provided in **Appendix D, Table 6-1**. Biased soil sample summary results for the pit surveys are provided in **Appendix D, Table 6-2**.

Pit A/B

Confirmation survey activities in SEAD-12 Pit A/B included a GWS and collection of 22 systematic surface soil samples. Pit A/B is 564 m^2 in area. Three biased soil samples were collected based on the results of the GWS. Biased sample S12EXSW-N-10-01 was collected at the location of highest gamma activity along the northeast sidewall of Pit A. The GWS is displayed in **Appendix D**, **Figure 7-1**. Systematic and biased sample locations are displayed in **Appendix D**, **Figure 7-2**.

Pit C

Confirmation survey activities in SEAD-12 Pit C (consisting of Pits C1 and C2) included a GWS and collection of 50 systematic surface soil samples. Pit C is 2,903 m^2 in area. Additional biased soil sampling was performed based on the results of the GWS. Biased sample S12EXSW-N-10-01 was collected at the location of highest gamma activity along the southwest sidewall of Pit C1. Biased sample S12EXSW-E-1-01 was collected at the location of highest gamma activity on the excavation sidewall of Pit C1. Biased sample S12EXFL-K-3-01 was collected at the location of highest gamma activity on the excavation floor of Pit C2. GWS results for pits C1 and C2 are displayed in **Appendix D**, **Figures 7-3** and **7-5**, respectively. Systematic and biased sample locations for pits C1 and C2 are displayed in **Appendix D**, **Figures 7-4** and **7-6**, respectively.

3.6 CONSTRUCTION COSTS

The total construction costs for the RA at SEAD-12 were approximately $1,225,000. The cost breakdown is as follows:

Engineering/Oversight	$295,000
Construction	$815,000
Analytical Laboratory	$115,000

4.0 UPDATED HUMAN HEALTH RISK ASSESSMENT

Human health risk assessments for Disposal Pits A/B and C were prepared and included in the Final SEAD-12 Remedial Investigation (RI) Report in August 2002. Potential carcinogenic risks and non-carcinogenic hazard indices were estimated for four current and future recreational/conservation receptors and an adult, child, and lifetime resident based on exposure to site surface and subsurface soils, groundwater, surface water, and sediments. The media-specific datasets used for estimating risks and hazard levels associated with groundwater, surface water and sediment exposures were based on SEAD-12 site-wide data that were collected during the RI and the earlier Expanded Site Investigation (ESI) of the area. The datasets used for surface and subsurface soils were based on Disposal Pit area-specific data that were collected from Disposal Pit A/B and Disposal Pit C during the RI and ESI.

Soils within Disposal Pits A/B and C were excavated and disturbed during the removal action conducted to recover and secure military-related items. More than 5,400 tons of material excavated from these Disposal Pits were characterized and disposed at a licensed, off-site landfill during the removal action, while more than 130 tons of mixed recyclable metals were recovered and sent to a metal recycler for recovery, and more than 13 tons of military-related items were secured by the Army and disposed of.

New chemical and radiological data for soil that remains at the excavated burial pit sites was obtained from each of the former Disposal Pit locations and these data have been discussed and summarized in earlier sections of this report. The newly collected chemical results have been compared to State of New York unrestricted use soil cleanup objective (SCOs) levels. Similarly, the newly collected radiological results have been assessed relative to background levels of radioactivity that are present at another burial pit location in the general vicinity of the SEAD-12 Disposal Pits where no radiological wastes or debris was identified. These comparisons suggest that site soils at each of the former SEAD-12 burial pit locations achieve the soil cleanup objectives defined by the State of New York, and as such unrestricted use might be allowed; however, radiological results suggest that the levels of ^{226}Ra in the vicinity of Disposal Pits A/B and C may be elevated relative to background, while ^{232}Th levels are generally consistent with those previously reported for the SEAD-63 burial site.

To more fully assess the potential risks and hazards that may still be present the SEAD-12 Radiological Waste Burial Site Disposal Pits, the Army has updated the human health risk assessments previously reported for these locations in the SEAD-12 RI Report. The technical memorandum providing specific details of the updated risk assessment conducted for the chemical contaminants in soil is provided in its entirety as **Appendix H** of this report. Complete details of the radiological constituent risk assessment update that has been prepared is contained in **Appendix D**, **Section 7** and **Attachments C – G** of this report (*Radiological Confirmation Survey Report* [Cabrera, 2011]). The following discussion presents and summarizes the findings and conclusions of the updated human health risk assessments that have been prepared.

The datasets that have changed based on the performance and completion of the military-related item removal action are the site-specific chemical and radiological soil datasets that were used for Disposal

Pits A/B and C. Datasets for groundwater, surface water, and sediment remain unchanged because no new data for samples from these media were collected as part of the removal action performed.

The prior soil datasets used for Pit A/B and C were individually replaced by a new total soil dataset prepared for Pit A/B and C. These datasets are comprised of analytical results that were collected during the RI or ESI and which are outside of the area of the work sites that have been excavated combined with new analytical data that were collected during excavation confirmatory sampling and backfill characterization and qualification activities performed. Confirmatory soil sample results from historic Disposal Pits A/B locations have been merged with backfill characterization sample results for the Overburden/C1 Stockpile that was used as backfill in this location and RI and ESI soil sample data from beyond the excavation sites to update this dataset. As assembled, the Disposal Pit A/B soil dataset contains results from a maximum of 60 soil samples that were collected from the area of this historic burial site. Confirmatory soil sample results collected from locations within excavations opened for removal of military-related items from Pits C1 and C2 (collectively Pit C) have now been combined with historic ESI and RI soil sample results to yield a dataset that now contains results from 85 samples.

4.1 SITE-SPECIFIC DATA EVALUATION CONSIDERATIONS

The RI Report (Parsons, 2002) and the *SEAD-12 Construction Completion Report* (Parsons, 2011) provide data on the nature and extent of radiological constituents present at the SEAD-12 site. These site constituents were designated based on the operational history of each area, including the chemicals and radionuclides known or suspected to have been used at each specific area.

4.1.1 Identification of Chemical Constituents of Potential Concern

Non-radiological (i.e., chemical) contaminants found in soil evaluated in this risk assessment (i.e., Contaminants of Potential Concern [COPCs]) were selected by comparing maximum detected concentrations (MDCs) left at an exposure point location (i.e., Disposal Pit A/B or C) with USEPA Regional Screening Level (RSLs) for residential soil (June 2011 Version). Published RSL values for carcinogenic chemical compounds were used at USEPA's listed value, which corresponds to a target cancer risk of 1×10^{-6}; comparator RSLs for non-carcinogenic chemical compounds were reduced by a factor of 10 (i.e., 0.1 times the listed RSL value), which corresponds to a hazard quotient of 0.1. Chemicals with concentrations below the comparator RSLs were eliminated from the list of COPCs evaluated in the updated risk assessments. Chemicals with no available screening values and chemicals with detected concentrations above the screening values were retained as COPCs. In addition, all members of a chemical class that had any member selected as a COPC were also retained as COPCs (e.g., all detected carcinogenic polycyclic aromatic hydrocarbons [cPAHs] were retained as COPCs if any one cPAH was identified as a COPC based on the aforementioned screening process), if they were detected at any level in a Disposal Pit's soil dataset.

Fifty six (56) soil contaminants, including 10 VOCs, 19 SVOCs, five pesticide/PCBs and 22 metals were initially evaluated as COPCs for Disposal Pit A/B. After the screening of the Pit A/B COPCs, three cPAHs and seven metals were retained as COPCs, and due to the selection of three cPAHs, four

other cPAHs that were also detected in the soil at Disposal Pit A/B, but which were not observed to exceed screening values, were also retained as "chemicals of the same group" (CSG) for further evaluation in the risk assessment. In addition, three other SVOCs and four other metals were also retained as COPCs in the risk assessment based on the determination that no comparator RSL screening value existed for them.

Comparably, 58 soil contaminants, including nine VOCs, 18 SVOCs, seven pesticides and 24 metals/cyanide were initially evaluated as COPCs for Disposal Pit C. Based on screening versus RSL comparator values, four cPAHs, one organochlorine pesticide, and nine metals were retained as COPCs. Four other SVOCs, one organochlorine pesticide, and four metals were also retained for further evaluation based on the determination that no comparator RSL screening value existed for them. Due to the retention of the four cPAHs, the other three cPAHs were also retained as "chemicals of the same group" (CSG), and one additional organochlorine pesticide was retained since it was an isomer of the two other organochlorine pesticides that were retained.

Data for the identified metal COPCs for Pit A/B and C were then compared to SEDA background soil concentrations found for the same metals to assess whether there was any indication that the metals found at the disposal pit excavation site could be attributed to the release of material from activities historically conducted in the area of concern (AOC), or could be associated with natural conditions. This comparison had been used and allowed during the risk assessment performed during the 2002 RI, and was repeated in the update to ensure that data processing procedures used in both risk evaluations were equivalent. The comparison to background was performed using the Wilcoxon-Mann-Whitney (WMW) Test provided in the USEPA's ProUCL Software package (version 4.01.004). This analysis procedure was used in place of the Wilcoxon Rank Sum test that was applied to the SEAD-12 datasets during the SEAD-12 RI.

The results of the WMW Test for the 11 Pit A/B metals retained indicate that mean concentrations for six of the 11 retained metals are lower than comparable values reported for sample concentrations in the SEDA background dataset. Therefore, the concentrations of these six metals in Disposal Pit A/B cannot be distinguished from background concentrations and there is no definitive indication that a contaminant release has occurred at the site. The WMW analysis for four other metals (i.e., calcium, potassium, selenium, and thallium) indicate that levels found in the vicinity of former Disposal Pit A/B are higher than those identified in the background soil, so these metals are retained as COPCs for further analysis under the risk assessment. The WMW results for sodium provided conflicting information as the results indicate that all of the tested hypotheses (i.e., site equals background, site greater than or equal to background, site less than or equal to background) were true. However, since it is not mathematically possible for two datasets to be greater than and less than each other at the same time it is assumed that the sodium concentrations found at Disposal Pit A/B and the background are equal, and that no release of sodium is likely to have occurred at Disposal Pit A/B. Therefore, based on risk assessment pre-screening and background evaluations, 14 COPCs (i.e., 10 SVOCs, four metals) were evaluated for soil in the updated risk assessment for Disposal Pit A/B.

The results of the WMW Test for the 13 Pit C metals retained indicate that mean concentrations of eight of the retained metals are lower than comparable values reported for sample concentrations in the SEDA background dataset. Therefore, effects from these metals cannot be distinguished from those of background conditions, and these metals are removed as COPCs. WMW Test results for the other five metals indicate that residual Pit C concentrations were higher than background, so these metals are retained as COPCs in the risk assessment. Therefore, based on risk assessment pre-screening and background evaluations, 19 COPCs were evaluated for soil in the updated risk assessment for Disposal Pit C.

Screening of chemical COPCs in other media (groundwater, surface water, and sediment) of interest at SEAD-12 were performed in a similar manner during the original RI.

4.2 IDENTIFICATION OF RADIOLOGICAL CONSTITUENTS OF POTENTIAL CONCERN (ROPCS)

In this section, the methodology used to select ROPCs is presented. ROPCs differ from site constituents in that the ROPCs are the constituents that have been detected at the site that have gone through an extensive screening process and are retained for quantitative analysis in the risk assessment. Four different types of screenings were performed to identify ROPCs for the SEAD-12 site. The following sections summarize the screening processes.

4.2.1 Data Reduction

For radiological constituents, any daughter product with a half-life of less than 180 days was not evaluated during this assessment. A six-month cutoff half-life was selected in the radiological dose and risk model. The risk model assumes that these decays products (daughters) are in secular equilibrium with respect to the parent radionuclide. Therefore, their contributions are already incorporated in the dose conversion factor (DCF) and risk coefficients of the parent. Due to this,

- Actinium-228 ([^{228}Ac] half-life = 6 hr), daughter product of Radium-228 (^{228}Ra), was evaluated as ^{228}Ra.
- Lead-214([^{214}Pb] half-life = 27 minutes) and Bismuth-214 ([^{214}Bi] half-life = 20 minutes), daughters of ^{226}Ra, were not inputted as separate source terms in the model.
- Lead-212 ([^{212}Pb] half-life = 11 hours), Bismuth-212 ([^{212}Bi] half-life = 61 minutes), and Thallium-208 ([^{208}Tl] half-life = 3 minutes), daughters of Thorium-228 (^{228}Th) were not inputted as a separate source terms in the model.
- Thorium-227 ([^{227}Th] half-life = 19 days), Radium-223 ([^{223}Ra] half-life = 11 days) and Lead-211 ([^{211}Pb] half-life = 36 min) are daughter products of Actinium-227 (^{227}Ac), and none of these were inputted as separate source terms in the model.
- Thorium-234 ([^{234Th}] half-life = 24 days), daughter product of Uranium-238 (^{238}U), was not inputted as a separate source term.
- The half-life of Lead-210 (^{210}Pb) is 22.3 years. After a thorough analysis of the data, of the 20 of 42 samples where ^{210}Pb was detected, the uncertainty associated with those results were

usually 75-100% of the result. In the 22 of the 42 samples where ^{210}Pb was not detected, the results averaged 18.42 pCi/g. In these same results, the ^{226}Ra values averaged 1.62 pCi/g. Since ^{226}Ra decays directly to ^{210}Pb, the results would be expected to be much closer to a 1:1 ratio in soils. Gamma spectroscopy does not provide accurate results for ^{210}Pb in soils due to the difficulty in detecting its low energy (49 kev) gamma photon when it decays. The more common and accurate method to analyze for ^{210}Pb is alpha spectroscopy for polonium-210 (^{210}Po), which is a daughter product of ^{210}Pb. Given these reasons, ^{210}Pb sampling results were not used to determine the EPC for ^{210}Pb. The EPC for ^{210}Pb was set equal to that for ^{226}Ra during the dose and risk evaluation for the disposal pits.

4.2.2 Weight-of-Evidence Screening

The weight-of-evidence screening was performed for all radiological constituents that passed the data reduction screening. If the frequency of detection for a radionuclide in a medium is five percent (5%) or less (i.e., a minimum of one detection out of 20 analytical results), generally, the radionuclide is excluded from further evaluation. This rationale is consistent with USEPA's RAGS guidance (USEPA, 1989). Under this screening, radiological constituents that were detected in less than 5% of the samples from a given medium may be artifacts in the data due to sampling, analytical, or other problems, and may not be related to site activities. These constituents were not included in the assessment.

4.2.3 Background Screening

The background screening was performed for all radiological constituents that passed the first two screenings. This screening consisted of comparing the maximum detected concentration against background sample criteria. Background samples were collected during the BRA, and these results are included in **Attachment C** of Cabrera's Report (**Appendix D**). If the maximum detected concentration was below background criteria, the site constituent was not considered for risk screening. However, if the site constituent was present at concentrations above background criteria, that site constituent was retained for risk screening.

4.2.4 Risk-Based Screening

Risk-based screening for radionuclides present in soil cannot be performed as there are no soil screening values for radionuclides available in the guidance documents supplied by NYSDEC and USEPA. However, risk-based screening was performed for radiological constituents that are present in the groundwater and surface water. Under the risk screening, the maximum detected concentration of the radionuclide was compared against their corresponding USEPA maximum contaminant level (MCL). Any radionuclide that exceeded the MCL was retained as a ROPC for the Site.

4.3 EXPOSURE ASSESSMENT

This section describes the receptors and exposure pathways evaluated in the updated risk assessment. The objectives of the exposure assessment were to estimate the magnitude, frequency, duration, and routes of potential human exposures to COPCs and ROPCs at the Disposal Pit AOCs. Potential receptor groups are identified in the exposure assessment and estimates of exposure or chemical and

radionuclide intake are calculated based on assumptions regarding exposure pathways and exposure parameters. The following sections of the report summarize the exposure assessment process utilized during this risk assessment.

4.3.1 Receptors

The human health risk assessment previously conducted for the Disposal Pits in the 2002 RI Report was completed based on the assumption that land within the AOC would be used for recreational or conservation purposes. Since the submittal of the 2002 RI, SCIDA has re-designated use of the land within SEAD-12 for use as future institutional and training areas. In addition, a tenant has leased a portion of SEAD-12 and is currently using the property for commercial purposes (telecommunications/data warehousing). Nevertheless, the Army updated the risk assessment for Disposal Pits A/B and C in SEAD-12 on the basis that the land will be used for conservation/recreational purposes. The selection of the conservation/recreational activities use for this property makes the risk assessment prepared more conservative (i.e., more stringent because it applies restrictive exposure assumptions) than would one that assumes use of the property for institutional/training purposes, which is more aligned with commercial purposes. In addition, a future 30-year resident (for COPCs) and a future 30-year resident farmer (which assumes consumption of homegrown produce, meats, and dairy products affected by site ROPCs) has been evaluated to assess potential risks and hazards to receptors under the unrestricted use scenario. The residential receptors are provided to address the State of New York's goal for site remediation to "restore the site to pre-disposal conditions, to the extent feasible and authorized by law". Both the resident and resident farmer scenarios assume that six years of the 30-year duration are experienced as a child, 0 to 6 years of age, while 24 years of the 30-year exposure period are lived as an adult (age 18 to 42 years). Therefore, for this update of the SEAD-12 risk assessment the following receptors were evaluated:

1. Current site worker,
2. Future park worker,
3. Future recreational visitor (child),
4. Future construction worker,
5. Future adult and child resident (for hazard assessment), and
6. Future lifetime resident (for COPC carcinogenic risk assessment) and future resident farmer (for ROPC carcinogenic risk assessment and dose assessment).

4.3.2 Identification of Exposure Pathways

Exposures are estimated only for pathways that are considered plausible and complete. A complete exposure pathway possesses the following four elements:

1. a source and mechanism for chemical or radionuclide release,
2. an environmental transport medium,
3. an exposure point, and
4. a human receptor and a feasible route of exposure at the exposure point.

A pathway cannot be completed unless each of these elements is present. **Figure 4-1** illustrates the completed exposure pathways for SEAD-12 Disposal Pit AOCs.

4.3.3 Sources and Receiving Media

Historic maintenance, testing, storage, and disposal operations conducted within the former WSA are the source of potential chemical and radiological contaminants that have been found present at, and within the vicinity of, the Disposal Pit AOCs. Soil may be impacted directly as a result of these operations. Groundwater may be affected due to leaching of potential contaminants in the soil. Sediment and surface water may be affected due to run-off from the affected disposal areas.

4.3.4 Integration of Exposure Pathways

The proper framework of an exposure pathway involves a source, transport medium, exposure point, and an exposure route. The pertinent exposure pathways for SEAD-12 are summarized in **Figure 4-1**. According to RAGS (USEPA, 1989a), a pathway is considered incomplete if one or more of these components is not present. Hence, if there is not a complete pathway, there can be no risk resulting from that theoretical pathway. For the purposes of this updated risk assessment, current and future human exposure pathways have been identified as potential pathways which meet the criteria for an exposure pathway.

The following pathways were not quantified based on the rationale below:

1. Exposure to surface water and sediment while swimming on-site were considered to be unrealistic exposure pathways because the depth of drainage ditches is at most only a few inches. Only occasional, incidental contact with surface water and sediment are evaluated.
2. Ingestion and dermal contact with soil by current off-site area residents was eliminated from the risk assessment based on the unlikely occurrence of a trespasser at SEAD-12. Perimeter security fences remain in place around SEAD-12 and the commercial tenant occupying land to the north and northwest of the former disposal pits controls access to the area via a security force. Land to the south of the former Disposal Pits is controlled by the Army, the SCIDA, and the Seneca County Sheriff's Department.
3. The most realistic current on-site exposure scenario is the site worker scenario. Because the assumptions are based on present data, it was determined that modeling a future site worker would yield no different risks than the current land use scenario.

4.3.5 Summary of Exposure Pathways Quantified

The pathways presented reflect the current onsite and the projected future onsite use of the former Disposal Pit Sites and the larger area of SEAD-12. This section presents the rationale for including exposure pathways in this risk assessment.

Direct Gamma Radiation

External gamma is an important pathway of exposure for radiological constituents, and therefore, it was quantified in this evaluation. This pathway is not applicable for chemical constituents (COPCs).

Inhalation of Particulate Matter in Ambient Air

Surface soil particles may become airborne via wind erosion or mechanical disturbances, or chemicals that are adsorbed onto soil particles may volatilize and be inhaled by receptors present at the site. Therefore, inhalation exposure to dusts and vapors in ambient air was assessed for all current and future onsite receptors for both COPCs and ROPCs.

Incidental Ingestion of On-Site Soils

Humans routinely ingest small amounts of soil or soil-like materials each day, primarily as a result of hand-to-mouth activity. As a rule, young children ingest larger quantities of such materials than do older children and adults, exclusive of construction workers. Soil ingestion is frequently an important pathway of exposure and therefore, was quantified for COPCs and ROPCs in this risk evaluation.

Dermal Contact to On-Site Surface Soils

During the course of daily activities, an on-site worker, recreational visitor, construction worker, or resident/resident farmer could have dermal contact with site soils. Dermal contact with soils could result in absorption of COPCs through the skin, therefore dermal adsorption is usually considered as complete pathway for chemicals; however, ROPCs are typically metals and do not easily pass through the skin, and as such, the dermal pathway was not evaluated for ROPCs.

Ingestion of Groundwater

The shallow groundwater aquifer underlying SEAD-12 is not currently used as a drinking water source. The shallow groundwater aquifer present throughout SEAD-12 and SEDA as a whole, has routinely been proven inadequate with respect to both yield and quality, affected by wide seasonal variations of storm event fed replenishment and the known quality impacts arising from the native soil metals content of the Devonian shale-derived clay/till strata that underlies the Site. Therefore, it is unlikely that a groundwater supply well will be installed in the future for use by future users of the site as an alternative municipal potable water supply exists and distribution lines are present in the area of SEAD-12. Nonetheless, since groundwater use is not prohibited or restricted via an institutional control, the Army has assumed that wells will be installed on site and used to provide potable water; this provides a degree of conservatism to any risk or hazard level predicted in the risk assessment. Therefore, groundwater use is considered a complete pathway and data from the on-site wells are used to calculate exposure concentrations. Exposure via ingestion of groundwater containing COPCs and ROPCs was assessed for a future outdoor park worker, a future recreational visitor, and a future resident / resident farmer.

Inhalation and Dermal Contact (Submersion) with Groundwater while Showering

Recreational visitors and residents may come into contact with groundwater while taking daily showers. These receptors may be exposed to COPCs contained in groundwater during showering by dermal contact and volatile chemicals that partition into the air via inhalation. Therefore, this is considered a complete pathway and COPC data from the on-site wells are used to calculate exposure

concentrations. Exposure via inhalation of groundwater and dermal contact (submersion) was assessed for a future recreational visitor. These pathways were not evaluated for ROPCs.

Incidental Dermal Contact to Surface Water and Sediment

There are drainage ditches throughout SEAD-12. Surface water runoff captured in these ditches and the associated wet soil, or sediment, may contain COPCs that have been mobilized from the AOCs. Park workers, recreational visitors, and residents may contact and have their skin exposed to surface water or sediment and be exposed to COPCs that are contained in these media. Therefore, exposures to surface water and sediments COPCs via dermal contact were assessed for a future recreational visitor, a future outdoor park worker and a future resident. Potential impacts from a park worker's dermal contact with surface water containing ROPCs was also evaluated assess potential short-term effects that may be present.

Incidental Ingestion of Surface Water and Sediment

Exposure to surface water and sediment while swimming on-site were considered to be unrealistic pathways of exposure because the depth of drainage ditches is at most only a few inches. As a conservative approach, accidental ingestion of surface water and sediment was considered for only onsite residential receptor scenario. However, exposure to surface water and sediment while wading were evaluated for a downstream receptor in Reeder Creek.

When the drainage ditches are dry, there is potential for contact with the sediment contained in the ditches. While dermal contact with this sediment has been addressed above, there is also the potential that a future resident/resident farmer might ingest some of this sediment (similar to soil ingestion). Ingestion exposure to sediment would be limited, since the sediment would often be covered by surface water or snow. Exposure to sediment by ingestion was assessed quantitatively for a future resident only.

4.4 UPDATE OF COPC RISK CHARACTERIZATION RESULTS

Risk characterization results for soil samples were only updated to estimate potential risk and hazard level changes that have resulted due to changes in COPCs and contaminant concentrations present at Disposal Pits A/B and C due to the completion of the removal action and new post-action soil sampling that was performed. Estimated carcinogenic risks and non-carcinogenic hazard levels predicted during the SEAD-12 Remedial Investigation arising from exposure to SEAD-12 groundwater, surface water, and sediment have only been updated to address new toxicity or reference dose concentrations that may have occurred since the *Remedial Investigation Report at the Radiological Waste Burial Sites (SEAD-12)* (Parsons, 2002) was issued. Radiological risk characterization results have been updated for all media of interest (soil, surface water, sediment, groundwater) due to the collection of the new analytical results for soil, and the evolution and advancement of the RESRAD model that has occurred since the 2002 RI Report was issued.

A detailed discussion of the updated risk assessment process employed to estimate risk and hazard levels due to COPCs remaining at the SEAD-12 site are summarized in **Appendix H** (*Technical Memorandum, Updated Risk Assessment, Radiological Waste Burial Sites*) of this Report. A detailed

discussion of the update of the risk assessment conducted for the ROPCs is provided in **Appendix D** (Cabrera, 2011), **Section 7**, with supporting data and information provided in **Attachments C** through **G** of that document. The discussions presented below in the remainder of this Section present and summarize the findings of these two separately performed operations.

The USEPA-recommended limit for the non-carcinogenic hazard index (HI) is 1.0. The USEPA upper limit for the cancer risk level is $1x10^{-4}$ and its preferred limit is $1x10^{-6}$ or lower.

4.4.1 Risk Assessment Update - COPCs

4.4.1.1 Disposal Pit A/B

The table presented below summarizes the calculated reasonable maximum exposure carcinogenic risks and the non-carcinogenic hazard indices for all receptors due to all chemical (non-radiological) exposure scenarios considered in this risk assessment for Disposal Pits A/B.

Receptor	Hazard Index	Cancer Risk
Current Site Worker	2.1E-04	3.6E-08
Outdoor Park Worker	1.2E-01	2.0E-05
Recreational Child Visitor	3.1E-01	2.0E-05
Construction Worker	1.1E-02	4.7E-08
Adult Resident	9.6E-01	--
Child Resident	2.8E+00	--
Lifetime Resident	--	7.0E-04

Current Site Worker

Three chemical exposure routes were evaluated for the site worker. The total cancer risk from all chemical exposure routes is below the USEPA target range for the RME. Likewise, the total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Outdoor Park Worker

Six chemical exposure routes were evaluated for the outdoor park worker. The total cancer risk from all chemical exposure routes is within the USEPA target range for the RME. The total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Recreational Visitor (Child)

Eight chemical exposure routes were evaluated for the child recreational visitor. The total cancer risk from all chemical exposure routes is within the USEPA target range for the RME. The total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Construction Worker

Three chemical exposure routes were evaluated for the construction worker. The total cancer risk from all chemical exposure routes is below the USEPA target range for the RME. Likewise, the total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Resident

Nine chemical exposure routes were evaluated for the future resident. For the RME, the total cancer risk from all chemical exposure routes, 7.0×10^{-4}, exceeds the USEPA target range. The total non-cancer hazard index from all chemical exposure routes for the adult resident is below, while the child resident's hazard index exceeds (HI = 2.8) USEPA's preferred limit of 1.

Dermal Contact with groundwater and surface water are the exposure routes responsible for the calculated RME cancer risk. The chemical that drives both of the noted carcinogenic risk levels is benzo(a)pyrene: cancer risk for dermal contact to groundwater equals 3.3×10^{-4}; cancer risk for dermal contact to surface water equals 2.2×10^{-4}.

The adult and child resident's elevated HI are primarily driven by dermal contact with surface water, with other significant impacts from ingestion of groundwater, and lesser contributions from dermal contact and inhalation of with groundwater. The non-carcinogenic hazard quotient due to the presence of chrysene in surface water is the contaminant most responsible for the noted HI increases; chrysene impact was not quantified in the RI because no dermal RfD was identified. The noted hazard indices increase for the adult and child resident is due to ingestion of cobalt in the groundwater, which was not quantified in the RI risk assessment. The noted increase in the HI levels due to dermal contact with groundwater is also attributable to cobalt.

4.4.1.2 Disposal Pit C

The next table summarizes the calculated reasonable maximum exposure carcinogenic risks and the non-carcinogenic hazard indices for all receptors due to all chemical (non-radiological) exposure scenarios considered in this risk assessment for Disposal Pits A/B.

Receptor	Hazard Index	Cancer Risk
Current Site Worker	2.6E-04	2.2E-07
Outdoor Park Worker	1.2E-01	2.2E-05
Recreational Child Visitor	3.1E-01	2.0E-05
Construction Worker	1.0E-02	1.7E-07
Adult Resident	9.6E-01	--
Child Resident	2.8E+00	--
Lifetime Resident	--	7.0E-04

Current Site Worker

Three chemical exposure routes were evaluated for the current site worker at Pit C. The total cancer risk from all chemical exposure routes is below the USEPA's target range of $1 \times 10^{-4} - 1 \times 10^{-6}$, based on a RME. Likewise, the total non-cancer hazard index from all exposure routes is less than 1.

Future Outdoor Park Worker

Six chemical exposure routes were evaluated for the outdoor park worker at Pit C. The total cancer risk from all chemical exposure routes is within the USEPA's target range for the RME. The total non-cancer hazard index from all exposure routes is less than 1 for the RME.

Future Recreational Visitor (Child)

Eight chemical exposure routes were evaluated for the child recreational visitor at Pit C. The total cancer risk from all chemical exposure routes is within the USEPA's target range for the RME. The total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Construction Worker

Three chemical exposure routes were evaluated for the future construction worker at Pit C. The total cancer risk from all chemical exposure routes is below the USEPA's target range for the RME. Likewise, the total non-cancer hazard index from all exposure routes is less than one for the RME.

Future Resident

Nine chemical exposure routes were evaluated for the future resident. For the RME, the total cancer risk from all chemical exposure routes, 7.0×10^{-4}, exceeds the USEPA target range. The total non-cancer hazard index from all chemical exposure routes for the adult resident is below, while the child resident's hazard index exceeds (HI = 2.8) USEPA's preferred limit of 1.

Dermal Contact with groundwater and surface water are the exposure routes responsible for the calculated RME cancer risk. The chemical that drives both of the noted carcinogenic risk levels is benzo(a)pyrene: cancer risk for dermal contact to groundwater $= 3.3 \times 10^{-4}$; cancer risk for dermal contact to surface water 2.2×10^{-4}.

The adult and child resident's elevated HIs are primarily driven by dermal contact with surface water, with other impacts from ingestion of groundwater, and lesser contributions from dermal contact and inhalation of with groundwater. The quantitation of a non-carcinogenic hazard quotient due to the presence of chrysene in surface water is the contaminant most responsible for the noted HI increases; chrysene impact was not quantified in the RI because no dermal RfD was identified. The noted hazard indices increase for the adult and child resident is due to ingestion of cobalt in the groundwater, which was not quantified in the RI risk assessment. The noted increase in the HI levels due to dermal contact with groundwater is also attributable to cobalt.

4.4.2 Risk Assessment Update - ROPCs

4.4.2.1 Disposal Pit A/B

The table presented below summarizes the anticipated dose and cancer risk that results due to receptor exposure to ROPCs in all media at Disposal Pit A/B. The State of New York's threshold radiation dose is 10 mrem/year. The USEPA's recommended cancer risk range is $1 \times 10^{-4} - 1 \times 10^{-6}$ with a preference for lower risk levels. Review of the summary data presented below indicates that all anticipated radiological dose levels are below the identified guidance range, while the anticipated cancer risk arising from exposure to ROPCs at the Disposal Pit site range from a high of 1.1E-05 for

the resident farmer (within the USEPA's recommended range) to levels below the USEPA's recommended range for the current site worker, the recreational visitor and the construction worker.

Receptor	Dose[1]	Cancer Risk
Current Site Worker	0.02	4E-07
Outdoor Park Worker	0.30	3E-06
Recreational Child Visitor	0.11	2E-07
Construction Worker	0.74	2E-07
Lifetime Resident Farmer	1.9	1.1E-05

1 Units for Dose are mrem/yr; guidance value limit is 10 mrem/yr

4.4.2.2 Disposal Pit C

The table presented below summarizes the anticipated dose and cancer risk that results due to receptor exposure to ROPCs in all media at Disposal Pit C. Review of the summary data presented below indicates that all anticipated radiological dose levels are below the identified guidance range, while the anticipated cancer risk arising from exposure to ROPCs at the Disposal Pit site range from a high of 4.1E-05 for the resident farmer (within the USEPA's recommended range) to levels below the USEPA's recommended range for the current site worker and the construction worker.

Receptor	Dose[1]	Cancer Risk
Current Site Worker	0.05	9E-07
Outdoor Park Worker	0.7	1E-05
Recreational Child Visitor	0.3	2E-06
Construction Worker	0.7	5E-07
Lifetime Resident Farmer	1.9	4.1E-05

1 Units for Dose are mrem/yr; guidance value limit is 10 mrem/yr

4.4.3 Cumulative Assessment of Site Hazards, Dose, and Cancer Risk Levels

4.4.3.1 Disposal Pit A/B

The table presented below summarizes the anticipated non-carcinogenic hazard, dose, and cancer risk levels that result due to receptor exposure to COPCs and ROPCs in all media at Disposal Pit A/B. The State of New York's threshold radiation dose is 10 mrem/year. The USEPA's recommended cancer risk range is $1 \times 10^{-4} - 1 \times 10^{-6}$ with a preference for lower risk levels, while its recommended non-carcinogenic hazard level is 1. Review of the summary data presented below indicates that all anticipated radiological dose levels are below the identified guidance range, while the anticipated non-carcinogenic hazard indices for all receptors except the child resident are below USEPA's preferred limit of 1. The anticipated carcinogenic risks for all of the conservation/recreation receptors evaluated are within or below the USEPA's recommended risk range, while the lifetime resident's/resident farmer's estimated cancer risk exceeds USEPA's preferred upper limit.

Receptor	Hazard Index	Dose[1]	Cancer Risk
Current Site Worker	2.1E-04	0.02	4.4E-07
Outdoor Park Worker	1.2E-01	0.30	2.3E-05
Recreational Child Visitor	3.1E-01	0.11	2.0E-05
Construction Worker	1.1E-02	0.74	2.5E-07
Adult Resident	9.6E-01	--	--
Child Resident	2.8E+00	--	--
Lifetime Resident/Resident Farmer	--	1.9	7.1E-04

1 Units for Dose are mrem/yr; guidance value limit is 10 mrem/yr

4.4.3.2 Disposal Pit C

The table presented below summarizes the anticipated non-carcinogenic hazard, dose, and cancer risk levels that result due to receptor exposure to COPCs and ROPCs in all media at Disposal Pit C. Review of the summary data presented for Pit C below indicates that all anticipated radiological dose levels are below the identified guidance range, while the anticipated non-carcinogenic hazard indices for all receptors except the child resident are below USEPA's preferred limit of 1. The anticipated carcinogenic risks for all of the conservation/recreation receptors evaluated are within or below the USEPA's recommended risk range, while the lifetime resident's/resident farmer's estimated cancer risk exceeds USEPA's preferred upper limit.

Receptor	Hazard Index	Dose	Cancer Risk
Current Site Worker	2.6E-04	0.05	1.12E-06
Outdoor Park Worker	1.2E-01	0.7	3.2E-05
Recreational Child Visitor	3.1E-01	0.3	2.2E-05
Construction Worker	1.0E-02	0.7	6.7E-07
Adult Resident	9.6E-01	--	--
Child Resident	2.8E+00	--	--
Lifetime Resident/Resident Farmer	--	1.9	7.41E-04

1 Units for Dose are mrem/yr; guidance value limit is 10 mrem/yr

Review of the preceding six tables indicates the estimated child resident's non-carcinogenic hazard indices and the lifetime resident's/resident farmer's carcinogenic risk levels exceed USEPA preferred limits. Both of these exceedances result primarily due to the exposure of the child or lifetime resident's exposure to chemical, and not radiological, constituents. The three most significant exposure pathways contribution to the child resident's elevated non-carcinogenic hazard index level are dermal contact with surface water (1.6), ingestion of groundwater (0.55), and dermal contact with groundwater (0.42). The lifetime resident's cancer risk is impacted by their dermal contact with groundwater (4.3E-04), and their dermal contact with surface water (2.5E-04).

With reference to the child resident's non-carcinogenic hazard index, the chemicals responsible for the 1.6 HI reported for dermal contact with surface water included Aroclor-1242 and chrysene. Arochlor-1242 was detected in two samples, and chrysene was detected in one of the surface water samples collected during the RI. Neither of these compounds are very soluble in surface water, so it is likely that there detection in any surface water sample results occurs due to the presence of soil particles in the sample that is being analyzed. Furthermore, the single chrysene detection was reported as an estimated concentration and was found in the duplicate of a sample-duplicate pair for which a non-detect value was reported for the sample. This further suggests that sampling errors may contribute to the value reported. Finally, both of the Aroclor-1242 results were found in surface water sample locations that are isolated from the Disposal Pit locations, and where it is unlikely that surface water runoff from the disposal pits could have entered the affected drainage channels. The single chrysene detection was found at a sample location that is hydraulically upgradient of the Disposal Pit sites, so it is likely that this material, if actually present, was released from a location not associated with the historic disposal pit operations.

Dermal contact to groundwater containing di-n-octylphthalate was the next highest contributor to the elevated HI that is noted for the child resident. This compound was detected in six out of 89 groundwater samples characterized during the RI, each time in a different well, and always at concentrations that were reported as estimated values. These wells are spread throughout the SEAD-12 site, although each of these wells was sampled at least twice during the RI, the phthalate was only detected in one of the two samples. Similarly, while ingestion of groundwater containing total dichloroethene was also noted as a significant contributor to the child's elevated HI, it was only detected in one well, once, and neither of its daughter isomers (cis- and trans-1,2-dichloroethylene) were ever noted in any other well at the SEAD-12 site. The single sample it was found in was collected from MW12-37, which was previously located next to Building 813/814 where a trichloroethene plume was found. This plume was remediated during the supplemental RI that was completed in 2004 and 2005.

Therefore, based on this information the elevated non-carcinogenic HI reported for the child resident over-estimates the true level of potential hazard present in the area of the SEAD-12 Disposal Pits.

The lifetime resident's elevated cancer risk results primarily due to dermal with groundwater (4.3E-06) and dermal contact with surface water (2.5E-06), both of which contain cPAH compounds. As noted above, it is unlikely that cPAHs readily are soluble in either surface water or groundwater, so it is more probable that their presence in the samples collected during the RI results from the capture of some amount of particulate that has these material sorbed onto the particles captured during the sampling process. Closer examination of the groundwater data indicate that four cPAHs contribute to the estimated cancer risk, but of these three were detected one each, while the other was detected in two samples collected from two separate well. All of the measured levels in groundwater were estimated, and for benzo(a)pyrene which was detected twice, it was not detected in the well when it was sampled the second time. Three cPAHs are the primary contributors to the noted carcinogenic risk arising from dermal contact with surface water, and again each of these was only detected in one sample (all collocated).

The removal of these overestimates of carcinogenic risks for the lifetime resident reduces the estimated level of carcinogenic risk to a level of approximately 1E-04, which is consistent with the upper level of USEPA's preferred risk range.

4.5 RISK CHARACTERIZATION RESULTS FOR LEAD EXPOSURES

Determination of receptor exposure to lead was not performed as part of this risk assessment since lead was not identified as a contaminant of concern in any of the datasets analyzed during this assessment.

4.6 UNCERTAINTY ASSESSMENT

The methodology used in this risk assessment is consistent with USEPA risk assessment guidance documents. All risk assessments involve the use of assumptions, judgments, and imperfect data to varying degrees. This results in uncertainty in the final estimates of risk. Assumptions built into the risk assessment in general, overestimate rather than underestimate potential risks, but occasionally can result in underestimating risk. In the following section, an evaluation is presented of the sources of uncertainty in the assessments and the relative influence of these sources on the results of the evaluation. The results of the assessments are presented in terms of the potential for adverse effects based upon a number of conservative assumptions. The tendency to be conservative is an effort toward protecting health. Uncertainty can be found at all phases in the risk assessment: in the analytical data, the exposure assessment, the toxicity assessment, and the risk characterization. Where uncertainty does exist, the BRA uses conservative assumptions to ensure that the outcome will be protective.

For example, there is uncertainty in the initial selection of substances used to characterize exposures and risk on the basis of the sampling data and available toxicity information. Other sources of uncertainty are inherent in the toxicity values for each substance and the exposure assessments used to characterize risk. Finally, additional uncertainties are incorporated into the risk assessment when exposures to several substances across multiple pathways are summed. Areas of uncertainty in each risk assessment step are discussed below.

4.6.1 Uncertainty in Data Collection and Evaluation

Uncertainties in the data collection/evaluation step of the risk assessment focus on determining whether enough samples were collected to characterize the risk, and if sample analyses were conducted in a qualified manner to maximize the confidence in the results. Results of the sample analyses were used to develop a database that includes a complete list of the chemicals by media and their representative concentrations used in the risk assessment. The sampling and analysis for this risk assessment included soil, surface water, sediment, and groundwater components of the comprehensive RI effort that was undertaken at the site in the 1998 to 2002 time frame, and focused confirmatory soil sampling that took place as part of the RA. Therefore, the samples collected and characterized were not collected randomly but were collected either from areas of the site known or suspected to be contaminated (RI samples) or from areas where the sampling and analysis effort focused on the attainment of an acceptable cleanup level. This type of non-random sampling biases

the data collected, in the case of the RI toward overestimating chemical concentrations from the site, as opposed to the RA sampling where lesser levels of contamination are sought.

The judgmental bias in the sample collection also limits the applicability of statistics to the database. Because the statistics used to calculate the upper limit of the 95th-percentile confidence interval assume that the data represents a randomly distributed population, and the database does not, there is inherent uncertainty in the application of statistics. Collection of non-random, judgmental samples was necessary to characterize the nature and extent of contamination that is an objective of the site investigations and actions.

All chemicals detected that were potentially site-related were retained in this assessment. Chemicals that were never detected were eliminated from the assessment. This practice may slightly underestimate risks due to low levels (i.e., below the sample quantitation limit) of eliminated chemicals. Since the RI samples were collected at areas where concentrations were expected to be high, it is very unlikely that any chemicals were present at the site at health-significant levels and not detected in at least one sample. However, if this did occur, this assumption will underestimate risk. The 95th UCLs were used to calculate site-related risks. Since that assumption implies chronic exposure to the 95th UCL concentration, this assumption is likely to overestimate risk.

For surface water, sediment, and groundwater data collected during the RI, if a chemical was detected, it was retained in the risk assessment regardless of how frequently it was detected. To calculate the upper limit of the 95th-percentile confidence interval, chemicals were assumed present in all samples in a media. When the chemical was not detected in a sample, one-half of the SQL was used. Especially for chemicals that were detected in only a few samples, the upper limit of the 95th-percentile confidence interval probably greatly overestimates the amount of the chemical present and, consequently, the risk from the chemical.

Comparatively, all soil data collected during the RI and RA and used to comprise the dataset for the risk evaluation, if a chemical was detected, it was retained in the risk assessment regardless of how frequently it was detected. The EPC for this media was based on the USEPA's ProUCL software package, where either the highest of the recommended UCL values was used as the EPC, or in the event that the recommended UCL value exceeded the maximum detected at the site, the maximum was substituted in its place. This computational and selection process probably leads to the overestimation of the chemical present and, consequently, the risk predicted from the chemical in soil.

The database also includes a number of data validation flags, indicating uncertainty in the reliability of the performance of the analyses done by the laboratory. Flagged data were retained following RAGS guidance.

4.6.2 Uncertainty in Exposure Assessment

There are inherent uncertainties in predicting future land uses and future chemical concentrations. Future land use scenarios were based on current plans for redevelopment of this portion of SEDA. Current land uses were identified by characterizing the site's physical setting.

A large part of the risk assessment is the estimation of risks for a broad set of exposure scenarios and pathways. If exposure does not occur, no risks are present. This assessment does not factor in the probability of the exposure occurring. For certain pathways, exposure may be extremely unlikely. For example, the future park worker, the future recreational visitor and the future resident all are assumed to ingest groundwater under exposure pathways assessed even though it is unlikely that such future use will ever be needed or realized due to the presence of an alternative, non-groundwater derived source of potable water at the site.

Once pathways are identified, exposure point concentrations must be estimated. There is always some doubt as to how well an exposure model approximates the actual conditions receptors will be exposed to at a given site. Key assumptions in estimating exposure point concentrations and exposure assumptions and their potential impact on the assessment are described in the following paragraphs.

There are many factors that determine the level of exposure for each exposure pathway. These factors include inhalation rates, ingestion rates, exposure frequencies, exposure durations, body weight, etc. The values for these exposure factors must be selected by the risk assessor to represent each receptor. For the RME scenarios particularly, upper bound values were selected for each exposure factor. In the calculations of RME exposure, these multiple upper-bound exposure factor estimates compound to yield intakes and absorbed doses that overestimate likely exposure levels.

There is further uncertainty in the quantitative dermal exposure assessments for soil and sediment, since these assessments have been limited to just five compounds with credible dermal absorption factors. Many other compounds were measured in soil and sediment that might be absorbed through the skin, although reliable quantitative absorption factors are not available. Ignoring this larger group of chemicals results in quantitative exposure estimates (absorbed doses), which underestimate the true potential exposures from dermal contact. Consequently, any risk associated with these compounds is also underestimated.

There is considerable uncertainty in the quantitative dermal exposure assessments for surface water (during swimming or wading) and groundwater (during showering). USEPA has cautioned that its recommended approach for calculating dermal exposures to organic chemicals in water may be overly conservative. USEPA expressed concern that for some compounds its model estimates absorbed dose from dermal exposure during showering that are much greater than the dose from ingestion of 2 L/day of water. USEPA further states that model validation is difficult due to a lack of data. This effect is most notable for compound with high estimated Kp values (Kp > 0.1 cm/hr), such as PCBs and PAHs. Consequently, risks associated with these compounds may be overestimated.

There is also uncertainty associated with using oral toxicity values to calculate dermal risks. As seen in the literature, there are differences between oral and inhalation absorption efficiencies. These differences vary and will likely cause either underestimation or overestimation of dermal risks. The efficiencies are generally within 1 order of magnitude of each other, so the uncertainty introduced is less than 1 order of magnitude.

The EPCs derived from the measured chemical concentrations are assumed to persist without change for the entire duration of each exposure scenario. It is likely that some degradation would occur over time, particularly for some of the organic compounds that would reduce the current concentrations. Therefore, this steady state assumption tends to overestimate exposure levels.

4.6.3 Uncertainty in Toxicity Assessment

Of the chemicals of potential concern, a number had no reference dose or slope factors. Several of these compounds have toxicity information such as weight of evidence classification indicating a strong potential for adverse health effects, particularly lead. The absence of toxicity values of these chemicals tends to underestimate risks.

There is considerable uncertainty inherent in the toxicity values for both carcinogens and noncarcinogens. Many of the studies are based on animals and extrapolated to humans, and in some cases, subchronic studies must be used to assess chronic effects. Most cancer slope factors are calculated using a model that extrapolates low dose effects from high dose animal studies. Because toxicity constants are generally based on the upper limit of the 95th-percentile confidence interval or incorporate safety factors to compensate for uncertainty, chemical-specific risks may be overestimated.

Toxicity information was not available for dermal exposure; hence, several assumptions had to be made which may tend to over- or underestimate risk. Oral toxicity values were used without adjustment to calculate risks from dermal exposure because the USEPA has not derived toxicity values for this route of exposure. However, values found in the literature (Owen, 1990) indicate that the uncertainty associated with using oral absorption to estimate dermal absorption is likely less than one order of magnitude. This is due to the lack of scientific studies available to quantify dermal toxicity and carcinogenic potential for the vast majority of priority pollutants and because chemical specific information needed to convert ingested dose to absorbed dose is not available.

4.6.4 Uncertainty in Risk Characterization

Uncertainties in the toxicity assessment are compounded under the assumption of dose additivity for multiple substance exposure. That assumption ignores possible synergisms and antagonisms among chemicals, and assumes similarity in mechanisms of action and metabolism. Synergism is the amplification of one chemical's toxic effect by the presence of a second chemical. For example, it is known that smokers also exposed to asbestos have higher lung cancer incidence than either smokers or asbestos workers alone. Ignoring synergism to the extent that it may occur at environmental levels tends to underestimate risk. Antagonism is the reduction of one chemical's toxic effect by the presence of a second chemical. For example, certain foods (such as broccoli) contain chemicals believed to be anti-carcinogenic. Ignoring antagonism tends to overestimate risk. Risks summed for chemicals having various weight-of-evidence classifications as well as different target organs may also tend to overestimate risk.

4.6.5 Uncertainty Pertaining to Dermal Risks from PAHs in Water

There is considerable uncertainty associated specifically with dermal exposures PAHs in groundwater and surface water at SEAD-12. Areas of uncertainty are discussed below:

1. Low frequency of detection. Benzo(a)pyrene was detected in just two of 89 groundwater samples and one of 52 surface water samples. The statistical treatment of these datasets to develop EPCs is highly uncertain, since it is dominated by "non-detect" values and the underlying distributions cannot be determined. Potential exposures to compounds detected so sporadically cannot be characterized with confidence.

2. Compound detected in one of two sampling rounds. Benzo(a)pyrene in groundwater was detected in just one of two sampling rounds from the same two set of wells. Therefore, its presence is unconfirmed in the second set of tests. Benzo(a)pyrene in surface water was detected in the first study phase, the ESI, but not in the second study, the RI.

3. Concentrations reported below the Sample Quantitation Limit (SQL). The detected results for benzo(a)pyrene in both groundwater and surface water were estimated values below the SQL. Identification and quantitation near the analytical detection is highly uncertain, and these results may be artifacts of the analytical process.

4. Dermal exposure modeling is highly uncertain. USEPA believes that its recommended model for estimating absorbed doses of organic compounds from dermal contact with water may overestimate true potential doses, with factors used here being even more conservative than recent guidance. This would tend to further discount the risk associated with dermal exposure to benzo(a)pyrene (future risk assessment calculations will utilize the lower adherence factor values). Absorbed doses from dermal exposure that greatly exceed the ingestion dose from the same water are counterintuitive and do not appear to be realistic. The model has not been adequately validated.

5.0 VARIATIONS FROM THE PLANNED WORK ACTIONS

The Army issued the *Draft Work Plan for Removal Action at the Radiological Waste Burial Pits Sites (SEAD-12)* (Work Plan) on May 12, 2009. The USEPA issued comments on the Work Plan on July 9, 2009. Mobilization to the site and field work associated with the removal action began on July 13, 2009, before there was time to respond to USEPA comments, prepare revisions to the Work Plan, and reissue the Work Plan for further review and approval. The decision to move forward with the field activity prior to responding to comments received was predicated on the Army's desire to move forward with the process of securing military-related items that were presumed to be buried at the site, and to take advantage of the summer and fall seasons when construction could most readily be performed. This decision was based in large part by the Army's knowledge that the planned excavation sites had previously been characterized during CERCLA site investigations and had been shown not to pose any unacceptable level of human health or ecological risk or threat.

The Army acknowledges that once field work began it became apparent that the historic burial pits contained a greater number and a wider variety of military-related items than had been anticipated prior to the work. In addition, certain of the recovered military-related items also were found to contain sufficient levels of radiation to warrant their continued management as low-level radioactive materials, pending their final demilitarization, dismantling, and their future disposal at a low-level radioactive disposal site. These materials continue to be held by the Army at the SEDA, pending their transfer to another Army contingent that is responsible for the ultimate declassification and release/disposal of such items.

As is documented and described throughout **Section 3** of this report, many modifications were made to the field operations originally planned as defined in the Draft Work Plan to address issues resulting from the discovery of the greater number and wider variety of military-related items than had been expected. Such modifications included the mobilization of additional field equipment and personnel (e.g., screening plant's radiation scanner array, field gamma spectrometer unit, health physicist, "mag and dig" team, EM-31, etc.) to deal with the increased number of military-related items recovered and the determination that much of it showed evidence of low-levels of radiation.

It is essential to note that with the exception of the 13.25 tons of military-related components that were secured by the Army and subsequently transfer for demilitarization and disposal as low-level radioactive waste, no evidence of hazardous waste was identified in any of the materials excavated from the historic disposal pits. The preceding section does indicate that finite levels of hazardous chemical substances were identified in the excavated soils and debris, but all of the identified levels identified were found to be below levels that the State of New York defines as being suitable for unrestricted use, or that are consistent with SEDA background levels for selected metals (e.g., nickel). Furthermore, there were no instances when competent or corroded drums or containers were recovered from the burial pits. There was also no evidence that municipal type trash or debris (e.g., paper waste, trash bags, miscellaneous cans, etc.), in the excavated burial pits.

General observations made during the excavation of these pits continue to suggest that the disposal of the materials at the burial pit locations were planned events, ones which were intended to secure

military-related items in a means that was normal (i.e., landfilled) during the period from the 1940s into the 1960s and 1970s. Visual evidence suggested that many of the buried items had been partially disfigured or dismantled prior to their placement in the burial pits, and that the accumulated total debris cache had been physically compacted to fit within defined burial pits.

After the excavation and recovery and separation of military-related items from other forms of C&D and miscellaneous debris, well characterized discrete waste and recycle streams were created and handled in the field. Military-related items with residual levels of radiation above local background levels were collected and disposed of as low-level radioactive waste. Other non-radioactive, military-related items were successfully dismantled or disfigured and were either sent off-site for disposal as miscellaneous debris at Seneca Meadows Landfill, or placed into the recycle stream for the recovery of metal content. Waste soils, possibly containing quantities of miscellaneous debris smaller than 6 inches in size, and known levels of hazardous chemical and radiological constituents were also sent to the Seneca Meadow Landfill where they have now been disposed, as cover material, in a controlled and monitored environment. Finally, other soils excavated from the burial pits that have been characterized and documented to contain levels of hazardous constituents that are consistent with or below New York State soil cleanup objectives that allow for continuing unrestricted use or surrounding background levels were used as fill at two of the historic burial pits (Pits A and B).

As a result of the completion of this removal action, the Army believes that no further action is required at the sites of the former burial pits within SEAD-12. The accumulated data indicates that materials that were left on site allow for the future use of this area for unrestricted use. Other areas within the greater bounds of SEAD-12 (e.g., area of former volatile organic compound groundwater plume near building 813/814) require continuing review and future actions, and these continuing plans will be addressed and discussed and defined in the pending Proposed Plan and Record of Decision for SEAD-12.

6.0 POST-CONSTRUCTION ACTIVITIES

Post-construction maintenance consists of periodic inspections of the site to determine if the areas of the historic burial pits and the associated work and support areas have reestablished vegetative growth. Seeding was completed by November 3, 2009. The site will be inspected during the spring or early summer of 2010 to determine the growth of vegetation.

7.0 CONCLUSIONS AND RECOMMENDATIONS

The Army conducted a removal action at the historic Radiological Waste Burial Pit site within the northeastern portion of SEAD-12 between July 13, 2009 and November 3, 2009. The objective of this work was to excavate material contained within the pits and allow the Army to examine the contents so that military-related items could be identified, removed, and secured, pending final demilitarization, dismantling, and disposal. The Army's motivation for removing the historic military-related items was to prevent them from being accessed by potential future owners or users of the SEAD-12 property, thereby allowing the property to be transferred for future beneficial reuse. Prior CERCLA investigations of the burial pit sites had indicated that military-related items were commingled with other debris, but that the combined disposed materials did not pose any unacceptable risk or threat to the environment or human health. The removal action also allowed the Army to more thoroughly examine and characterize other materials that had been placed in the pits to further ensure that previously unidentified hazardous substances were not contained, and that the historic disposal pits did not represent a potential future source of contaminant release.

Based on the completion of the removal action, the Army is now able to report that:

- Approximately 5,400 cy of soil were excavated from four historic burial pits of interest (i.e., Pits A, B, C1, and C2) within SEAD-12. Of the total quantity of material excavated from the pits, 5,423 tons of waste and debris was transported to the Seneca Meadows Landfill in Seneca Falls, New York for disposal in a regulated facility that is subject to continuing monitoring of environmental conditions. Most of the SEAD-12 material transported to the landfill (greater than 5,350 tons) was approved for use as cover material within the landfill, with the balance being disposed as C&D or miscellaneous debris.
- Approximately 122 tons of assorted scrap metals, including aluminum, iron, stainless steel, and copper, were transported to Luffman Metal Recyclers in Seneca Falls, New York for future sale to metal refiners.
- Approximately 13.25 tons of military-related items were disposed of at Energy Solutions LLC, Utah. These items were characterized and shown to contain low-levels of radioactive material.
- Seventeen thousand (17,000) gallons of water, including decontamination liquids, and groundwater and storm water that were pumped out of the excavations were characterized for chemical and radiological contaminants and were approved for disposal within the Seneca County Sewer District Number 2 wastewater treatment plant.
- Post excavation geophysical surveys of the work area showed that previously identified underground anomalies indicative of buried material caches had been removed and that there was no indication that buried debris was present anywhere within the former Radiological Waste Burial Pit area in the northeastern section of SEAD-12.
- Approximately 2,300 cy of overburden soil surrounding the deeper excavations and fill from Pit C1, which was found to contain principally C&D and miscellaneous debris, were characterized

for chemical and radiological contaminants and were found to be suitable for use as backfill at the excavation sites.

- Analytical results from 85 confirmatory soil samples collected from the base, sidewalls, and perimeter of the burial pit excavations were collected and characterized for chemical and radiological constituents. The results of the chemical analyses were compared to State of New York Unrestricted Use soil cleanup objective levels, and were found to be consistent with and below established guidance levels that allow for unrestricted use. The results of the radiological analyses were used as the basis of a RESRAD risk analysis, and the results indicated that the areas were suitable for release for unrestricted use.
- The update of the SEAD-12 human health risk assessment based site soil samples that remain in proximity to the former burial sites indicates that there is no unacceptable levels of carcinogenic risk or non-carcinogenic hazards associated with the levels of chemicals that are now documented to remain in the soil at the locations of former Disposal Pits A/B and C. Therefore, the levels of risk and hazard that remain at the sites of the excavations are equivalent to those previously identified during the Remedial Investigation of SEAD-12, which were previously accepted by the agencies based on the risk management and uncertainty discussion presented in the SEAD-12 Remedial Investigation Report.

As a result of the performance and completion of the removal action, the Army contends that all military-related items previously buried within the disposal pits have been removed. In addition, no hazardous waste were found to be present within the former disposal pits, and residual levels of chemical and radiological substances that are present at the former burial pit sites are sufficiently low as to allow for future unrestricted use and unlimited exposures. Based on this determination, it is the Army's intention to move forward with the preparation and submittal of a Proposed Plan and Record of Decision for SEAD-12, which will call for no further action at the burial pits site, but which will address other locations within the SEAD-12 site where land use controls are required.

Notes:

(1) Mean and minimum value calculated for compounds that do not exceed Unrestricted Use SCOs or EPA RSL Residential (1/10th non-carcinogenic) based on detected concentrations only.
If compound found at concentrations above Unrestricted Use SCO or EPA RSL Residental (1/10th NC), mean value derived from ProUCL version 4.00.04.

(2) 95th upper confidence limit of the arithmetic mean as defined by ProUCL version 4.00.04.

(3) Highlights for exceedance and the 95th UCL was computed:
- Yellow highlights are for compounds found to exceed NYSDEC Unrestricted Use Soil Cleanup Objective levels.
- Orange highlights are for compounds found to exceed EPA Regional Screening Levels for Residential (1/10th for non-carcinogenics).

Zinc	MG/KG	8	8	70.9	59.2	51.9		109	0		2,300	0	

Notes:

(1) Mean and minimum value calculated for compounds that do not exceed Unrestricted Use SCOs or EPA RSL Residential (1/10th non-carcinogenic) based on detected concentrations only.
If compound found at concentrations above Unrestricted Use SCO or EPA RSL Residental (1/10th NC), mean value derived from ProUCL version 4.00.04.

(2) 95th upper confidence limit of the arithmetic mean as defined by ProUCL version 4.00.04.

(3) Highlights for exceedance and the 95th UCL was computed:
- Yellow highlights are for compounds found to exceed NYSDEC Unrestricted Use Soil Cleanup Objective levels.
- Orange highlights are for compounds found to exceed EPA Regional Screening Levels for Residential (1/10th for non-carcinogenics).

Table 3-8

Notes:

(1) Mean and minimum value calculated for compounds that do not exceed Unrestricted Use SCOs or EPA RSL Residential (1/10th non-carcinogenic) based on detected concentrations only.
If compound found at concentrations above Unrestricted Use SCO or EPA RSL Residental (1/10th NC), mean value derived from ProUCL version 4.00.04.

(2) 95th upper confidence limit of the arithmetic mean as defined by ProUCL version 4.00.04.

(3) Highlights for exceedance and the 95th UCL was computed:
- Yellow highlights are for compounds found to exceed NYSDEC Unrestricted Use Soil Cleanup Objective levels.
- Orange highlights are for compounds found to exceed EPA Regional Screening Levels for Residential (1/10th for non-carcinogenics).
- Grey highlights are for compounds found to exceed both NYSDEC Unrestricted Use SCO levels and EPA Regional Screening Levels for Residential (1/10th for non-carcinogenics).

(4) Limited number of detects (less than 4 data points, 10-15 is recommended) used for 95th UCL calculation; most conservative recommended ProUCL value was used.

(5) Single detection used as 95th UCL value

INGESTION	NA	NA	NA	C	NA	C/R
DERMAL CONTACT	NA	C	NA	C	NA	C

C Pathway considered to pose potential chemical risk
R Pathway considered to pose potential radiological risk
NA Not applicable to receptor

Notes:
1. Additional exposure pathways considered for radiological constituents (using RESRAD) are plant, meat, and milk ingestion.
2. Site receptors exposed to total soil for chemical constituents (COPCs).
3. The Future Construction Worker receptor suface and total soil for radiological constituents (ROPCs).
4. For radiological parameters, submersion rather than dermal contact is considered.

Daily Report for SEAD-12 Removal Action
(W912DY-08-D-0003 TO #03; Job 746762)

Date	**Day**	**Weather Conditions**
Monday, June 29, 2009	Monday	Scattered rain/Thunderstorms, temperature in the 60's

Personnel On-Site (use Table, Insert, Rows above or below to add extra spaces**)**
Working Hrs 0600 – 1630 hrs

Affiliation	**Position**	**Name**	**Time or Hours**
Parsons	**Construction Manager**	**B. McAllister**	**12 hours**
	Site Manager	**Tom Andrews**	**10 hours**
	Tech	**Brendan Baranek-Olmstead**	**10 hours**

Equipment On-Site (use Table, Insert, Rows above or below to add extra spaces)

Type	**#**	**Type**	**#**	**Type**	**#**
Excavator	0	Dozer	0	Haul Trucks	0
Loader	0	Flat Bed Truck	0	Skid Steer	0
Cat Folk w/ bucket	0	Screening Plant	0	Water Storage	0
Generator	0	Pump	0		
Trimble Surveying	1	Dust Monitors 2x	0		
Port-a-John	0				

Health and Safety:
PPE Level(s) D

Tool Box Meeting **Time:** 0630 hours

Slips/Trips/Falls, hydration, sun screen, check for ticks, avoid contact with vegetation such as poison ivy.

Work Performed:

Laid out the site limits of SEAD-12 disposal pits A/B, C, and support area so that it can be mowed and sprayed to reduce the presence of poison ivy.
Base station was setup on SEAD-12A 1994 and QC checked on monument SEAD-12A-1 1994.

Sampling

No samples were collected.

Tool Box Meeting **Time:** 0630 hours

Discussed hazards of poison ivy exposure and importance of wearing safety vests

Work Performed:

Completed construction on 200 feet of road and two entrance ways with culverts for the truck turnaround.
Started excavation in Test pit A & B.
Approximately 600 cys were excavated, laid down, and tested for radiological signatures.
Radioactive material that appeared to be luminous dials was set aside.

Removed several pieces of classified material and set aside for Army inspection.
Overburden was contaminated with debris.

Sampling

No samples were taken.

Tool Box Meeting **Time:** 0630 hours

Discussed hazards of poison ivy exposure and importance of wearing safety vests

Work Performed:

Completed excavation of pit A & B.
Today 1200 cys of soil was excavated from Pit A, and in total approximately 1770 cys were excavated.
Pit A was photographed after the excavation was completed.
Approximately 500 cys of soil were excavated from Pit B.
Any radioactive material or classified material encountered was set aside.
Most overburden was contaminated with debris, however clean overburden was set aside.

Classified material was moved to a storage building.
Parsons/St George provided a flat bed since the Army did not have one as promised.
Plan to move screen plant to site next week, additional equipment will be required

Tool Box Meeting **Time:** 0630 hours

Discussed hazards of poison ivy exposure and importance of wearing safety vests

Work Performed:

Continued to screen C-1 material and move the final C-1 cut was to the overburden pile as per Tom Battaglia's orders.
Tom Battaglia said the Pit A, B, and C-2 should be screened and combined into one stockpile and no testing for disposal is to occur until all material is screened.
The dozer and cat fork lift were demobilized.
Third scrap box and roll off for debris disposal arrived on site.
It was decided that metal will be separated into Steel, Aluminum, and Ferrous.

Sampling
Excavations were sampled for clearance.

Health and Safety:
PPE Level(s) D

Tool Box Meeting **Time:** 0630 hours

Discussed hazards of poison ivy exposure, slips/trips/falls, and the importance of wearing safety vests

Work Performed:

Continued screening the material.
Separated large scrap and debris from piles prior to screening.
Army requests that all boxes be dumped and scanned piece by piece for radioactivity.
Collect any radiological material and set aside in secured B-25 boxes.
Once scanned, repack non-rad pieces of scrap metal for recycle and non-rad C&D for disposal at landfill.

Sampling

No samples were taken.

Tool Box Meeting **Time:** 0630 hours

Working in slippery conditions due to rain last night and working level of skid steer bucket. Ergonomics of hand held instruments using proper handle for the Ludlum 4020

Work Performed:

Parsons instructed St. George to use the excavator and lay out the >6" material so Cabrera could scan the pile. The estimated 50cy of material was scanned by both Patty Retka and Landon Collins in both directions with no items encountered above background.
The Army representative John Cleary then started visual inspection of the scrap metal that is staged on the ground. As the inspection and scanning occurred two laborers from St. George removed any questionable items that were identified by either Cabrera or the Army. Material was segregated by metal type and any identifiable electronic components such as thermal batteries or capacitors were removed.

These items were being placed in a separate location to be transported to Building 814 for storage and identification.
At 0800, two additional 40cy roll off boxes were delivered by Riccelli trucking. These will be used to store the scanned and inspected material as it is scanned by Cabrera and inspected by the Army.
At 1200 the first of the three empty 40cy roll off boxes was filled and the second one was in the process of being filled. Less than five items were removed from the first 40 cy of scrap metal including two dials and three potential magnesium thorium alloy items.
Building 803 was cleaned out and the staged rinsing water and collected debris was moved to the storage area to be sampled for disposal.
At 1230 received approval from the Army and COE that the screening plant could be demobilized. Second 40cy roll off is 3/4 full and no additional items were identified for removal from this roll off. St George has emptied the contents of the first two roll off boxes filled on 8/6 to remove thermal batteries and capacitors. This material was already inspected by the Army and scanned for radiological levels, and the only reason for re-inspecting the material was to remove batteries and capacitors.

Sampling
Samples for disposal characterization, Analytical composition and Gross A/B along with Gamma Spec are complete with the exception of confirmation samples within the excavated area for Gross AB and Gamma Spec. These sample locations and frequencies have yet to be determined since we are waiting for analytical results to determine if further excavation is required.

Tool Box Meeting **Time:** 0630 hours

Heavy equipment hand signals and high visibility PPE
Work Performed:
Ben McAllister, Michael Pierson and Landon Collins (Cabrera) are onsite to collect soil samples for Radiological testing. Seven samples were collected from the remaining excavated areas in pit C1 and pit C2. Trimble surveying equipment was setup and calibrated along with daily calibration of the 4420 Fiddler. Samples were labeled and COC generated for offsite shipment. St George services and Riccelli trucking are removing the offsite disposal material.

St George Enterprises loaded for shipment to the disposal facility 60 trucks provided by Riccelli trucking. This material was brought to Seneca Meadows for disposal. An estimated 1683.85 tons was reported by Riccelli Trucking at the end of the day.

Parsons has requested approval from the Army to bring in a off road haul truck to move the additional excavated backfill material from pit B and move backfill from the overburden/C1 pile to the pit A and pit B area. The approval of this truck will reduce the time to backfill and also reduce the disturbed area that will need to be re-vegetated after the backfill is complete. Both Army and USACOE representatives have approved the addition of the off road haul truck via telephone call and in person to Parsons Rep. Cabrera services conducted the post excavation radiological survey of the pit A area and area surrounding perimeter of pit B. An additional hot spot was identified in pit A that was excavated by hand and found to be a 6" by 3" piece of mag-thor alloy. This was removed and placed in the B-25 box currently at the site to store identified material. The area of the removal was scanned after the item was removed and found to be below background post removal.

Sampling

Seven soil samples from the excavation area C1 and C2 were collected and will be submitted for analyzes for Gross Alpha Beta content and Gamma Spec. The analysis of these samples will be provided by General Engineering Laboratories, Charleston SC.

Disposal
Army Representatives approved the removal of the first of 8 roll off containers containing recyclable scrap metal from the excavation and subsequent screening operation. Today the first of the 8 containers was removed from the site by Luffman Scrap metal. This 25cy container full of ferrous scrap metal and mixed stainless steel was removed. The representative from Luffman gave a preliminary appraisal of the dirty aluminum and mixed metal of between .34 and .22 cents per pound due to the presence of other metals within the aluminum. This preliminary appraisal was conveyed by telephone to Army representatives, who provided the verbal the approval to remove the remainder of the scrap aluminum and C&D debris tomorrow.

Disposal (Use right click, update field function to total Cumulative numbers)

1 container of ferrous recyclable metal 25cy.

Poison Ivy Decon procedures

Work Performed:
St George Enterprises loaded for shipment to the disposal facility 30 trucks provided by Riccelli trucking. An estimated 1000 tons was loaded and hauled offsite. Actual totals will be provided Monday by Riccelli Trucking

Riccelli trucking also hauled off site one roll off container of C&D and three of the five remaining roll off containers of recyclable metal. The recyclable metal was brought to Luffmann scrap metal of Seneca Falls, also hauled offsite by Luffmann srcap metal were two additional roll off containers of aluminum recyclable metal.

Mobilized to the site was one Komatsu off road haul truck to move the overburden backfill material to pit A and B and one Komatsu dozer to place the backfill. The Army is comfortable with overburden backfill results so that backfilling can be completed if regulatory approval is not received by Monday.

Sampling

67 soil samples from the excavation area pit A, B, C1 and C2 were submitted for analysis for Gross Alpha Beta content and Gamma Spec. The analysis of these samples will be provided by General Engineering Laboratories, Charleston SC.

Scanning
Cabrera scanned the remainder of the C1and C2 excavation and the entire lay down area with the Fidler 4420 in conjunction with the Pro XRS GPS to create a figure of the scanned area. One Hot spot was identified in the C2 excavation where a radium dial was found in the bottom of the C2 excavation. This dial was removed by Cabrera and placed in the B-25 box for storage. The area where the dial was removed was than rescanned after the removal and found to be at or below background levels.

Tool Box Meeting **Time:** 0600 hours
Avoiding Slip Trip Falls

Work Performed:
St George Enterprises backfilled by grading area A that was approved to backfill by USACOE. The Parsons dig team identified an area in the C2 area northeastern grid J3 with buried metal debris that could not remove by hand. When the excavator was brought in to remove this item upon removal an additional disposal pit was found that was separated from the C2 excavation. This additional area was excavated with the excavator and 6 truck loads of material estimated at 70 cy were brought to the lay down area and placed on plastic. The additional area measured 20X30 and is approximately 7 feet deep. Upon discovery of this additional area USACOE was notified and the removal and stockpiling was approved. As part of the approval USACOE rep requested that additional geophysical surveys of all excavated area be conducted before any more areas are backfilled. St George Enterprises agreed to take Tuesday off to

facilitate the additional survey of the excavated area and will work Wednesday, Thursday Friday 10 hours. In addition to this removal Em-31 Geophysical survey was conducted on the C2 area to identify any other disposal areas that may be located within the C2 area. Geophysical survey was conducted over the unexcavated area of C2 and the 25 feet of perimeter surrounding the excavation. During this survey two additional areas to the west in grids J2 and I2 were identified in the geophysical survey. These areas will be investigated tomorrow with the excavator and one St George operator.

Sampling
3 soil samples from the additional excavation area in the northeastern area of pit C2 were submitted for analysis for TCL-VOC, TCL-SVOC, Pets PCB, TAL-Metals and Gross Alpha Beta content and Gamma Spec. The analysis of these samples will be provided by Columbia Analytical Services for the analytical analysis and General Engineering Laboratories, Charleston SC for the radiological analysis.

Scanning
Cabrera scanned the remainder of the haul roads and additional C2 excavation area with the Ludlum 4420 in conjunction with the Pro XRS GPS to create a figure of the scanned area. One hot spot was identified in the material excavated from the additional C2 excavation. The source of the hot spot was removed by Cabrera and placed in the B-25 box for storage and future disposal. The remainder of the material will be scanned when the additional excavated material is laid out by St. George to be scanned by Cabrera.

Disposal (Use right click, update field function to total Cumulative numbers)

1 container of recyclable metal removed by Riccelli and brought to Luffmann Scrap Metal.

Tool Box Meeting **Time:** 0600 hours
Avoiding repetitive motion injuries

Work Performed:
With approval of USACOE the two additional areas identified in the previous days geophysical survey to the southwest of area C2 in grid J2 and I2 were excavated This additional area was removed with the excavator and the 20 truck loads of material estimated at 300 cy were brought to the lay down area and placed on plastic. Upon discovery of this additional area USACOE was notified and the removal and stockpiling was approved. St George Enterprises agreed to take Wednesday off to facilitate the additional survey of the excavated area and will work Thursday Friday 10 hours. In addition to this removal Em-31 Geophysical survey was conducted on the C1 area to identify any other disposal areas that may be located within the C1 area.

Daily Report for SEAD-12 Removal Action

(W912DY-08-D-0003 TO #03; Job 746762)

Sampling

5 soil samples from the additional excavation area in the Southwestern area of pit C2 were submitted for analysis for TCL-VOC, TCL-SVOC, Pets PCB, TAL-Metals and Gross Alpha Beta content and Gamma Spec. The analysis of these samples will be provided by Columbia Analytical Services for the analytical analysis and General Engineering Laboratories, Charleston SC for the radiological analysis.

Scanning

Cabrera scanned the additional C2 excavation area grid J2 and I2 with the Ludlum 4420 in conjunction with the Pro XRS GPS to create a figure of the scanned area. Material with elevated readings was identified in the excavated material from the southwest J2, I2 area of the C2 excavation. This material was brought to the lay down area to be scanned and hand sorted by Parsons dig team and Cabrera on Thursday.

Mag and Dig

The Parsons dig team removed surface and subsurface metal from 1 acre of the screening plant area and removed any metal that was identified. The team also checked the additional C2 areas for remaining metal before the excavator was moved from the site.

Geophysical Data Collection

Parsons collected EM-31 geophysical data over the entire C1 area consisting of an area 300 by 150 feet. This data was corrected for GPS lag and time corrected and provided to Parsons Geophysicist to process and map.

Disposal (Use right click, update field function to total Cumulative numbers)

1 container of recyclable metal removed by Riccelli and brought to Luffmann Scrap Metal.

Tool Box Meeting **Time:** 0700 hours
Safety Glasses

Work Performed:
Parsons completed collection of EM-31 Geophysical data in the excavated area and pick up data gaps from previous surveys. Samples were collected from Grid I2 and J2 the additional area excavated to the SW of C2. The area outside the excavated area was gridded out for upcoming EM-31 geophysical survey. The dig team completed .5 acres of surface metal removal and moved all removed items to the staging area to be scanned by Cabrera Services.
Cabrera Services scanned with the Ludlum 4420 the remainder of the I2 and J2 grids with no readings above background detected.

Sampling

.

Five samples from the I2 and J2 area were collected for chemical analysis, three sidewall samples, one floor sample and one perimeter; these samples were shipped to CAS for expedited turnaround. Samples from the I2, J2 and I3 area were shipped to General Engineering Labs for Gross alpha beta and gamma spec analysis. Along with these samples, five samples that had previously arrived at General engineering broken were recollected and shipped to General Engineering labs for Gross Alpha Beta and Gamma Spec analysis.

Disposal (Use right click, update field function to total Cumulative numbers)

Tool Box Meeting **Time:** 0700 hours
Frisk out procedure with GM

Work Performed:
In addition to the collection of geophysical data, 11 truckloads of material were shipped to the disposal facility. The material was loaded by St. George Enterprises into trucks provided by Riccelli trucking. The estimated 370 cy of material removed from area of Pit C2 in grids I2, J2 and J3 was laid out in the staging area in 8" lifts and scanned by Cabrera Services and Parsons dig team to remove debris.

Disposal
An additional 5 feet of the northern wall of the Pit B excavation was removed and brought to the staging area to be loaded out to the disposal facility. This material was removed based on the sample results of the perimeter sample S12EXPR-O-8-04 analyzed for PCBs. A result of 189 ug/Kg was returned from the lab that is 89.0 ug/Kg above the NYSDEC standard for Unrestricted Use. This material was added to the

staged area B material being loaded out to the disposal facility from the first 5 foot removal on the northern wall of area B

Geophysical Investigation
Parsons performed geophysical data collection on 2.5 acres of the additional area located outside the previously identified excavation area of SEAD 12. The data are being collected on 10 foot lane spacing using the Geonics EM-31 electromagnetic detector being operated in Vertical dipole mode. The additional data are being collected to identify potential anomalies that were not identified in the original 1996 survey.

The geophysical investigation of the excavated area has identified an additional area of investigation to the south east of the original Area A excavation area within the boundaries of the previously identified removal. When this area was investigated it was found be construction debris, fence posts, concrete and a well rusted chain link fence that had been previously buried in this area. At the time the material was removed USACOE Rep was informed and requested that the material along with associated construction debris be brought to the staging area and separated from the remainder of the C2/B material being stored and sorted there. The fence posts and concrete was removed from the overlying soil and the remainder of the material was staged in a pile in the lay down area.

Scanning and Sorting of Area C2 material
Cabrera Services in conjunction with Parsons dig team and St. George personnel scanned and sorted debris from the J2, J3 and I2 material removed from the Pit C2 area on Tuesday. The material was pushed out on plastic in the lay down area and all debris hand sorted to remove items identified by Cabrera Services as having radiological readings above background. Any items identified by Cabrera were moved to the B25 box for disposal and all other debris that was removed during the hand sort was laid out on plastic to be inspected by the Army when the scanning and sorting of this material is complete.

Cabrera Services scanned with the Ludlum to identify above background material while Parsons and St George personnel used hand shovels and the skid steer to remove the remaining debris from the laid out material. All recyclable metal was removed and sorted from the non recyclable trash in the lay out area.

Sampling.
No samples collected today

Tool Box Meeting **Time:** 0700 hours
Proper handling and storage of TLD badges

Work Performed:
In addition to the collection of geophysical data 4 truckloads of material was shipped to the disposal facility. The material was loaded by St. George Enterprises into trucks provided by Riccelli trucking.

The remaining 170 cy of material removed from area C2 in grids I2, J2 and J3 was laid out in the staging area in 8" lifts and scanned by Cabrera services and Parsons dig team to remove debris.

Disposal
4 trucks from Riccelli were loaded out with the remainder of the Pit B excavated material from yesterday

Geophysical Investigation
Parsons performed geophysical data collection on 4.5 acres of the additional area located outside the previously identified excavated area of SEAD 12. This data is being collected on 10 foot lane spacing using the Geonics EM-31 electromagnetic detector being operated in Vertical dipole mode. This additional data is being collected to identify potential anomalies that were not identified in the original 1996 survey.

The geophysical investigation of the excavated area has identified an additional area of investigation to the south east of the original Area A excavation area within the boundaries of the previously identified removal.

Individual targets from the Geophysical mapping in the excavated area were laid out to be investigated on Monday

Scanning and Sorting of Area C2 material
Cabrera Services in conjunction with Parsons dig team and St. George personnel scanned and sorted debris from the J2, J3 and I2 material removed from C2 on Tuesday. The material was pushed out on plastic in the lay down area and all debris hand sorted to remove items identified by Cabrera services as having readings above background. Any items identified by Cabrera were moved to the B25 box for disposal and all other debris that was removed during the hand sort was laid out on plastic to be inspected by the Army when the scanning and sorting of this material is complete.

Cabrera Services scanned with the Ludlum to identify above background material while Parsons and St George personnel used hand shovels and the skid steer to remove the remaining debris from the laid out material. All recyclable metal was removed and sorted from the non recyclable trash in the lay out area.

Sampling.
Two samples for PCB analysis method 8082 were submitted to CAS from the northern wall of the Pit B excavation. This area had an additional 5 feet of material removed yesterday to capture the material with elevated PCB results returned from the lab..

Tool Box Meeting **Time:** 0700 hours
Safe work procedures using hand tools

Work Performed:
Material from the additional C2 area at anomaly numbers P2, P3, P4, P5 was laid out in the staging area in 8" lifts and scanned by Cabrera services and Parsons dig team to remove debris. Military related debris was sorted from construction debris and laid out for inspection by the Army on Tuesday. The additional area excavated was surveyed for volume and elevation coordinates were provided to the office for sample quantity and volume estimation.

Disposal
None Today

Geophysical Investigation

Individual targets from the Geophysical mapping P2, P3, P4, P5 were investigated. In this additional excavation military related debris was removed from three of the four areas investigated and construction debris was removed from the fourth. The USACOE rep was informed of the additional excavation that was taking place in grids J1, J2, K1and K2. Parsons was instructed to continue the removal and take the debris to the lay down area to be sorted and scanned. This material was excavated with the overburden stockpiled on site and five truckloads of debris taken to the lay down area.

Scanning and Sorting of Area C2 material

Cabrera Services in conjunction with Parsons dig team and St. George personnel scanned and sorted debris from the J1, J2, K11, K2 grids removed from the C2 additional excavation. The material was pushed out on plastic in the lay down area and all debris hand sorted to remove items identified by Cabrera services as having readings above background. Any items identified by Cabrera were moved to the B25 box for disposal and all other debris that was removed during the hand sort was laid out on plastic to be inspected by the Army when the scanning and sorting of this material is complete.

Cabrera Services scanned with the Ludlum 4420 to identify above background material while Parsons and St George personnel used hand shovels and the skid steer to remove the remaining debris from the laid out material. All recyclable metal was removed and sorted from the non recyclable trash in the lay out area.

Tool Box Meeting **Time:** 0700 hours
Cold Work Procedures

Work Performed:
Material from the additional C2 area at anomaly numbers P2 to S3 was laid out in the staging area in 8" lifts and scanned by Cabrera Services and Parsons dig team to remove debris. Military related debris was sorted from construction debris and laid out for inspection by the Army. The additional area excavated was surveyed for volume and elevation coordinates were provided to the office for sample quantity and volume estimation. Material from the overburden stockpile was staged outside the C2 and B excavations to expedite backfilling and open the area under the stockpile for geophysical data collection.

Disposal
None Today

Geophysical Investigation

Individual targets from the Geophysical mapping P2 to S3 were investigated. In this additional excavation military related debris was removed from the excavated area and moved to the lay down area. The USACOE rep was informed of the additional excavation that was taking place in grids J4, J3, I4 and I3. Parsons was instructed to continue the removal and take the debris to the lay down area to be sorted and scanned. This material was excavated with the overburden stockpiled on site and 6 truckloads of debris taken to the lay down area to be sorted and scanned.

Scanning and Sorting of Area C2 material
Cabrera Services in conjunction with Parsons dig team and St. George personnel scanned and sorted debris from the J4, J3, I4 and I3 grids removed from the C2 additional excavation. The material was pushed out on plastic in the lay down area and all debris hand sorted to remove items identified by Cabrera services as having readings above background. Any items identified by Cabrera were moved to the B25 box for disposal and all other debris that was removed during the hand sort was laid out on plastic to be inspected by the Army when the scanning and sorting of this material is complete. Army Rep John Cleary was onsite to provide over site of the scrap metal sorting. A 40 cy roll off container was filled with the removed scrap metal and is ready to be taken off site.

Cabrera Services scanned with the Ludlum 4420 to identify above background material while Parsons and St George personnel used hand shovels and the skid steer to remove the remaining debris from the laid out material. All recyclable metal was removed and sorted from the non recyclable trash in the lay out area.

Health and Safety:
PPE Level(s) D

Tool Box Meeting **Time:** 0700 hours
Cold Work Procedures

Work Performed:
Material from the additional C2 area at anomaly numbers P2 to S3 was laid out in the staging area in 8" lifts and scanned by Cabrera Services and Parsons dig team to remove debris. Military related debris was sorted from construction debris and laid out for inspection by the Army. The additional area excavated was surveyed for volume and elevation coordinates were provided to the office for sample quantity and volume estimation. Material from the overburden stockpile was staged outside the C2 and B excavations to expedite backfilling and open the area under the stockpile for geophysical data collection.

Disposal
A second water storage tank was brought in to transfer the stored ground water and move the current water storage tank out of the geophysical investigation area. The analytical results of the sampled water have been received and will be provided to Romulus water dept for possible disposal.

Geophysical Investigation
Geophysical targets S5, S6, S7 were investigated and found to be related to surface debris. S6 was a pipe that was located at the surface in the C1 area. Geophysical targets S6 and S7 were associated with asphalt and construction debris that remains on the edge of the C excavation area. Geophysical data was collected in the area under the overburden stockpile, in the area between C1 and C2 where the water storage tank was removed.

Scanning and Sorting of Area C2 material
Cabrera Services in conjunction with Parsons dig team and St. George personnel scanned and sorted debris from the J4, J3, I4 and I3 grids removed from the C2 additional excavation. The material was pushed out on plastic in the lay down area and all debris hand sorted to remove items identified by Cabrera services as having readings above background. Any items identified by Cabrera were moved to the B25 box for disposal and all other debris that was removed during the hand sort was laid out on plastic to be inspected by the Army when the scanning and sorting of this material is complete. Army Rep John Cleary was onsite to provide over site of the scrap metal sorting. A 40 cy roll off container has been filled and was removed from the site.

Cabrera Services scanned the recyclable metal with the Ludlum 4420 to identify above background material. All recyclable metal was removed and sorted from the non recyclable trash in the lay out area. This metal once inspected by the Army was scanned by Cabrera with the Ludlum 4420 than placed in the scrap roll off. Any material identified during the scanning of the recyclable metals to be above background was placed in the B25 box and will be moved to the storage building once full.

Sampling.

No Samples collected today

Disposal (Use right click, update field function to total Cumulative numbers)
One 40 cy roll off of recyclable metal sent to Luffmann metal recyclers.

Scanning and Sorting of material

Daily Report for SEAD-12 Removal Action

(W912DY-08-D-0003 TO #03; Job 746762)

The scanning and sorting of C2 material has been completed and all remaining soil loaded out for offsite disposal. One 25cy roll off container was shipped offsite for recycling at Luffmann metal recyclers completing the scanning and sorting of excavated material.

Sampling.

Seven samples were collected from the C2 excavation area from grids J4, I4and I3 and shipped to Life Sciences labs for analysis of VOC, SVOC, Metals +cn, Pesticides, and PCB's for 4 day turn around. Samples were also sent to General Engineering Labs for Gross Alpha Beta and Gamma spec analysis on a 14 day turnaround. Two samples were collected from the northern side of the J3 grid after 12 inches of material was removed from the face of the excavation. This material was removed due to the presence of pesticides detected in samples SW-I-3-01, SW-I-3-02 and SW-I-3-03. The excavated material was removed and directly loaded to trucks to the disposal facility. Once the material was removed one sample was collected and submitted for pesticide analysis with a 4 day turnaround.

Disposal (Use right click, update field function to total Cumulative numbers)
One 25 cy roll off of scrap metal 35 trucks of soil brought to the disposal facility

Tool Box Meeting **Time:** 0700 hours
Hand protection and work glove use

Work Performed:
Backfill of the Area B excavation using staged overburden soil. The excavator, large dozer and haul truck were used to fill in this excavation. Water in the excavation was pumped to the water storage tank and the hole was backfilled and compacted using the Komatsu 65 dozer. The area between excavation Area A and Area B was graded to drain to the west. Parsons received approval from Romulus water department to discharge the stored ground water to the Water Treatment Plant #2. A water truck will be brought to the site to transport the 17,000 gallons of stored water to the water treatment plant. Cabrera services have scanned out the small Komatsu dozer and Komatsu skid steer. These two pieces of equipment will be removed from the site tomorrow.

Disposal
A conference call with Parsons, Army and Cabrera Services was conducted to agree on the removal of additional material from the C2 area in the K3 grid where sample results returned above average results. The participants of the call made the decision to remove an additional 24 cubic yards of material to

remove any remaining above background material. As the removal of the 24 cubic yards of material is conducted Cabrera services will continually scan the area to detect any potential above background material.

Geophysical Investigation
None
Scanning and Sorting of Area C2 material
Cabrerra Services scanned the K3 grid where sample results returned a above background results. No above background material detected.

Sampling
No Samples collected today

Work Performed:
Backfill of the Area C2 excavation using staged overburden soil, the excavator and large dozer were used to fill in this excavation. Parsons received approval from Romulus water department to discharge the stored ground water to the Water Treatment Plant #2. A water truck was brought to the site to transport the 17,000 gallons of stored water from the water storage tanks to the water treatment plant. Cabrera Services has scanned out the large Komatsu dozer, Cat 325 excavator and the haul truck. These three pieces of equipment will be removed from the site tomorrow.

Disposal
Two truckload of material was removed from the floor of the K3 grid in excavation area C2. Cabrera Services scanned the material prior to it being removed in 8 inch lifts. The material removed was direct loaded into trucks that brought it to the disposal facility. The entire area was scanned after the material was removed and no above background readings were detected. Once the 24cy of material was removed the area was backfilled and graded to drain to the north.

Geophysical Investigation
None

Scanning and Sorting of Area C2 material
Cabrerra Services scanned the K3 grid as material was removed in 8 inch lifts where sample results had identified an above background result. No above background material detected during any of the scans.

Sampling
Swipe samples for PCBs were conducted on the water storage tanks prior to them being removed from the site. Swipes were collected in the presence of the rental company representative and will be analyzed for PCBs using method 8082. One sample was collected from the floor of grid K3 (S12EXFL-K-3-02) this sample will be submitted for Gross Alpha Beta and Gamma spec analysis. It has been agreed that the area will be backfilled prior to receiving the results from the lab.

Work Performed:
Cabrera demobilization and shipped all equipment and sources to office. Parsons performed final electromagnetic surveys over the backfilled A, B and C2 areas to confirm that all metal material had been removed from the area. All EM and surveying equipment demobilized and office closed up. Demaria Landscaping Inc. will be onsite during the next available weather window to broadcast seed the disturbed area to stabilize the soil for the winter. The landscaper will return in the spring to repair any areas that do not vegetate this late in the season. This will be the final daily report for the field effort of this project.

Disposal
None

Geophysical Investigation
EM-31 MKII survey of areas A, B and C2 to confirm the complete removal of items associated with this removal action. The surveys were conducted in Vertical mode with 5 foot lane spacing used.

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the Inplace samples representing current site conditions
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Note:
(Q) = Qualifer
(U) = Uncertainty
U = Analyte was analyzed for, but not detected above the MDL, MDA, or LOD.
UI = Gamma Spectroscopy − Uncertain identification
Americium-241 and Cobalt-60 were not analyzed for these samples, but were presented to allow for cross comparison.

(1) The dataset of samples consists of the excavated samples taken from Pit B.
The overburden C1 samples were not included in this dataset.
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table.
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation.

Notes:
(1) The dataset of samples consists of the overburden C1 samples
The Inplace samples were not included in this dataset
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Notes:
(1) The dataset of samples consists of the overburden C1 samples
The Inplace samples were not included in this dataset
(2) NYSDEC's Unrestricted Use Soil Cleanup Objective, 6 NYCRR Part 375-6.8(a).
(3) Sample/Duplicate pairs are evaluated as separate and discrete samples in this table
(4) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs

U = compound was not detected
J = the reported value is an estimated concentration
UJ = the compound was not detected; the associated reporting limit is approximate
R = the analytical result was rejected during data validation

Note:
(1) The project plan called for utilizing the 609 keV Bi-214 gamma energy for quantifying Ra-226. Direct quantification of Ra-226 via gamma spectroscopy is prone to errors and high levels of uncertainty.
(Q) = Qualifer
(U) = Uncertainty
U = Analyte was analyzed for, but not detected above the MDL, MDA, or LOD.
UI = Gamma Spectroscopy − Uncertain identification
Americium-241 and Cobalt-60 were not analyzed for these samples, but were presented to allow for cross comparison.

Notes:
(1) These results have not been validated. Laboratory qualifiers shown.
(2) Hazardous Waste Regulatory Levels for Toxicity Characteristic
(3) A bolded and outlined cell indicates a concentration that exceeded the site-specific CUGs.

U = compound was not detected
J = the reported value is an estimated concentration

1.0 INTRODUCTION

Cabrera Services, Inc. (CABRERA) has prepared this *Radiological Confirmation Survey Report* for Parsons Infrastructure & Technology Group Inc. (Parsons), which was tasked under United States Army Corps of Engineers (USACE) Contract Number (No.) W912DY-08-D-0003, Task Order No. 0003, to perform a Removal Action (RA) of classified military-related materials and other debris from Disposal Pits A/B and C that are located at the Radiological Waste Burial Pit Sites (SEAD-12) within the former Seneca Army Depot Activity (SEDA) in Seneca County, New York. After the RA was completed, a confirmation survey of the remediated areas was performed to facilitate the release of the site for unrestricted use. Finally, a dose and risk assessment was performed to determine the risk attributable to the level of residual radioactivity distinguishable from background at the site.

Parsons prepared a project Work Plan (Parsons, 2009) under the assumption that the excavation would proceed in a manner similar to that performed by Plexus (with support from CABRERA) at SEAD-63 in 2004 (Plexus, 2005).

The excavation in SEAD-12 in 2009 resulted in the discovery of multiple radioactive military items, including dials containing radium and presumed facsimiles of classified system components containing thorium. Some limited contamination of soils, consisting of small dial fragments, was observed. CABRERA provided health physics support during the excavation of the disposal pits at SEAD-12. This included screening excavated soil in 1-foot lifts and removing any radioactive items before the soils were characterized and then either shipped off-site for disposal or used as backfill at the Site. The confirmation survey of the disposal pits was performed in accordance with the *Radiological Field Sampling Plan* (*FSP*; Parsons, 2009). Due to the discovered radiological items within the excavation, this confirmation survey was updated as described in the technical memorandum *Summary of Field Activities* (CABRERA, 2009), which is included in Attachment A of this report.

1.1 Background and Site History

The SEDA is located approximately 40 miles south of Lake Ontario, near Romulus, New York as shown on Figure 1-1. The SEDA previously occupied approximately 10,600 acres of land located in the Towns of Varick and Romulus in Seneca County, New York. The former military facility was owned by the United States (US) Government and operated by the Army between 1941 and approximately 2000, when the SEDA military mission ceased. Since 2000, more than 8,250 acres of land have been transferred from the Army to other public and private parties for reuse.

The mission of SEDA primarily entailed the management of munitions and included:

- Receiving, storing, and distributing ammunition and explosives;
- Providing receipt, storage, and distribution of items that support special weapons; and,

- Performing depot-level maintenance, demilitarization, and surveillance on conventional ammunition and special weapons.

SEAD-12 is located in the north central portion of SEDA within the former Weapons Storage Area (WSA), which is also known as the "Q" Area. As shown on Figure 1-1, SEAD-12 originally was originally defined by two separate areas designated as SEAD-12A located in the northeast corner of the WSA, and SEAD-12B located northeast of Buildings 803, 804, and 805 near the north central border of the Depot. SEAD-12A encompassed an area measuring approximately 1,000 feet (ft) long by 1,000 ft wide (approximately 93,000 square meters [m^2]), and contains Disposal Pits A/B and C. SEAD-12B encompassed an area measuring approximately 300 ft long by 300 ft wide (approximately 8,400 m^2), which was suspected to contain a buried 5,000 gallon underground storage tank and a small dry waste pit.

The bounds of SEAD-12 were increased to include approximately 360 acres of land after the completion of the Expanded Site Inspections in 1995. This decision was based on the similarity of the chemicals found at SEAD-12A and SEAD-12B, and the Army's knowledge of the general history and use of the Q Area, which suggested similar constituents could exist throughout the larger area.

The portion of SEAD-12 located north of Service Road No. 2 was used for disposal of laboratory and maintenance wastes, and military components. The northern portion of SEAD-12 also includes Buildings 802 through 807, 810, 812 and 825 which were part of the WSA facility at SEDA. The eastern, western, and southern portions of SEAD-12 are primarily open fields and include Buildings 813 through 817, 819, and 823. These buildings were also part of the former WSA facility at SEDA.

The area designated as SEAD-12 excludes the area of SEAD-63, the Miscellaneous Components Burial Site, which is located along the western boundary of the former Q Area (see Figure 1-1). A Non-Time Critical Removal Action was performed for SEAD-63 in 2004, resulting in the removal of 5,100 tons of soil and debris. A record of decision for No Further Action at SEAD-63 was submitted by the Army in September 2006, approved by the US Environmental Protection Agency (USEPA) with concurrence from the New York State Department of Environmental Conservation (NYSDEC), and the solid waste management unit is closed under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

1.2 Previous Radiological Studies

A remedial investigation (RI) was initiated at the expanded SEAD-12 in 1997 and the results were documented in the *Final RI Report* (Parsons, 2002). The RI investigation consisted of: geophysical, radiological, and soil gas surveys; sampling and analysis of subsurface and surface soils, groundwater, surface water, and sediment. The RI included the investigation of the entire 360-acre site, and included the focused analysis and summary of the resulting data on nine potential release areas that were defined based on their historic operations and use. Based on the results of the RI, three subareas of SEAD-12 (i.e., Disposal Pit A/B and Disposal Pit C [former SEAD-12A], and the Former Dry Waste Disposal Pit [former SEAD-12B]) were identified as most likely to pose a continuing threat to human health and the environment, and were carried through the entire risk assessment process. The results of the 2002 RI suggested that potential future risks due to chemical and radiological contaminants at each of these three subareas were within or below USEPA's preferred carcinogenic risk and non-carcinogenic hazard ranges, but further information suggested that military-related items and debris was likely to be present in the area of the former SEAD-12A (Disposal Pit A/B and C). The areas of Disposal Pit A/B, and C, which was further divided into Pit C-1 and C-2, are shown in Figure 1-2.

As part of the RI, seventy-seven (77) surface and subsurface soil samples were analyzed for radionuclides in the Disposal Pit A/B area, with 17 re-sampled to clarify the reported detection of Plutonium-239/240 (^{239}Pu/^{240}Pu) in the samples. Radiological soil sampling detected six isotopes (Bismuth-214 [^{214}Bi], Lead-210 [^{210}Pb], Lead-214 [^{214}Pb], Radium-223 [^{223}Ra], Radium-228 [^{228}Ra], and Tritium [^{3}H]) at levels that statistically exceeded background; however no isotopes exceed the background plus the derived concentration guideline level (DCGL) developed by Argonne National Laboratory (ANL) for use during the license termination effort at SEDA in 2003 (ANL, 2003). The re-sampling confirmed that the levels of the ^{239}Pu/^{240}Pu detections observed during the initial sampling event were a function of the detection limit and not actual levels present.

Ninety-eight (98) surface and subsurface soil samples were analyzed for radionuclides in the Disposal Pit C area with 13 re-sampled to clarify the reported detection of ^{239}Pu/^{240}Pu in samples. Radiological soil sampling detected six isotopes (^{214}Bi, ^{210}Pb, ^{223}Ra, ^{226}Ra, ^{228}Ra, and ^{3}H) at levels that statistically exceeded background; however no isotopes exceed the background plus DCGL. The re-sampling confirmed that the levels of the ^{239}Pu/^{240}Pu detections observed during the initial sampling event were a function of the detection limit and were considered false positives.

Shortly after beginning the SEAD-12 Removal Action in 2009 the discovery of the multiple radioactive military items, including dials containing radium and/or thorium, and presumed facsimiles of classified system components containing thorium, prompted the collection of three samples of material and four smear samples with activity detected above background. These samples were sent to GEL Laboratory LLC in Charleston, South Carolina, for quick screen gamma spectroscopy analyses involving gamma spectroscopy analysis without incorporating a delay time for ingrowth of isotopic progeny. The results were used to confirm the suspected radionuclides contaminants of concern (RCOCs) for this project. Table 1-1 lists the samples and detected results.

Table 1-1. Gamma Spectroscopy Quick Screen Results

SAMPLE ID	MATERIAL	DETECTED RADIONUCLIDES (1)
S12DS01; S12WS04	Brown sandstone material	Elevated natural uranium (^{238}U) progeny: ^{214}Bi (250 pCi/g); ^{214}Pb (249 pCi/g); ^{210}Pb (243 pCi/g) Elevated natural thorium (^{232}Th) progeny: ^{228}Ac (408 pCi/g); ^{212}Bi (258 pCi/g); ^{212}Pb (368 pCi/g); ^{208}Tl (157 pCi/g)
S12DS02; S12WS03	White metal piece	Elevated natural thorium (^{232}Th) progeny: ^{228}Ac (1,080 pCi/g); ^{212}Bi (685 pCi/g); ^{212}Pb (1,120 pCi/g); ^{208}Tl (403 pCi/g)
S12DS03; S12WS02	Clump of mud with paint/metal flakes	Radium (^{226}Ra) progeny: ^{214}Bi (2,080 pCi/g); ^{214}Pb (1,470 pCi/g); ^{210}Pb (1,960 pCi/g)
S12WS01	Smear of excavated component	No radionuclides reported as detected.

(1) Bi = bismuth; Pb = lead; Ac = actinium; Tl = thallium; Ra = radium.

A discussion of the samples with reported detections appears below:

- S12DS01: This sample consisted of the material identified during the initial baseline scanning survey of the surface footprint of Pit C-2. The location was flagged and excavated using shovels - the source material was found approximately six inches below the ground surface. Measurements returned to background levels following its removal.

  Based on the detection of radionuclides associated with both the naturally-occurring uranium and thorium decay series, the material is assumed to be unprocessed. One historical mission of SEDA was the storage of valuable ores, including pitchblende ore (in SEAD-48) and columbite ore. With the rock's location in the surface soil it is unlikely it was intentionally placed in the area for burial. No additional similar material was found over the course of the excavation and/or screening process.

- S12DS02: This sample was collected from the vicinity several items that had a large white-colored light metal sleeve with above-background radiation levels, and appears to be the same type of material. The results indicate the presence of natural thorium (Thorium-232 [^{232}Th]) progeny. The items themselves were not identified, but thorium alloys with aluminum, magnesium, and other light metals are common in aircraft parts and other components that must maintain structural integrity in high temperatures.

- S12DS03: This sample consisted of a clump of clay with small pieces of metal or paint, apparently from a damaged radium dial or gauge. The detection of three progeny of ^{226}Ra without detections of uranium decay series progeny above ^{226}Ra, such as Thorium-234 (^{234}Th) confirm the presence of radium.

To further assist in identification of the radionuclides present in components or debris, a Canberra Inspector 1000 portable multi-channel analyzer (MCA) was brought onsite. The Inspector 1000 system consisted of a Lanthanum Bromide detector to allow for quick identification of detected gamma energies. Measurements were conducted on excavated debris using the manufacturer's recommendations. A Cesium-137 (^{137}Cs) source was used during the measurement to provide a reference energy (662 kiloelectron Volt [keV]) to determine potential spectral shift due to temperature or other fluctuations in operating parameters.

1.3 Radiological Contaminants of Concern

Based on the field gamma spectroscopy results as well as the onsite screening with the MCA, the primary RCOCs for this project were determined to be ^{226}Ra and ^{232}Th with progeny in equilibrium assumed. A more detailed description of the determination of the RCOCs is provided in Section 4.3.

1.4 Objectives

USACE desires to decommission this site so it can be reused for other purposes without restrictions. In order to accomplish this, the confirmation survey data were compiled, combined with existing soil, groundwater, surface water, and sediment radiological data available from prior site studies, and these data were included as inputs to a residual dose and risk assessment. This dose and risk assessment was performed to confirm the following:

1) The level of residual radioactivity distinguishable from background at this site would result in a total effective dose equivalent to an average member of the critical group of 10 millirem per year (mrem/yr) or less as per NYSDEC standards (NYSDEC, 1993); and

2) The level of residual radioactivity represents an excess lifetime risk of cancer, at a point of exposure, to an average individual no greater than between 10^{-4} and 10^{-6}.

This page intentionally left blank

2.0 RADIOLOGICAL REMEDIAL SUPPORT SURVEYS

2.1 Equipment Release Survey Methodology

Fixed and removable activity surveys were performed on equipment before it was demobilized from the site. The alpha-beta counting instrumentation used to perform equipment release surveys during the SEAD-12 project is summarized in Table 2-1.

Table 2-1. Survey Instrumentation

INSTRUMENT	DETECTOR AREA	ALPHA EFFICIENCY	BETA EFFICIENCY
Ludlum 43-10-1/ 2929	100 cm^2 smear	0.3652	0.1814
Ludlum 43-89/ Ludlum	126 cm^2	0.1608	0.0664

In addition, equipment was qualitatively checked by scanning with a Ludlum 44-9 Geiger-Mueller (GM) pancake-type probe.

Each smear was collected over approximately 100 square centimeters (cm^2) of surface area and counted using a Ludlum Model 2929 alpha-beta smear counter. Surface contamination limits are listed in Table 2-2. One-minute direct static counts were collected on the pieces of machinery using a Ludlum Model 2224-1 scaler/rate meter with Ludlum Model 43-89 alpha/beta scintillator.

The release criteria from US Nuclear Regulatory Commission (NRC) Regulatory Guide 1.86 (NRC 1974) were used for evaluating fixed and removable activity levels. The acceptable contamination limits are summarized in Table 2-2. All equipment survey measurements were less than the contamination limits in Table 2-2.

Table 2-2. Acceptable Levels of Surface Contamination

RADIONUCLIDE[1]	ACCEPTABLE SURFACE CONTAMINATION LEVELS (dpm/100 cm^2)		
	REMOVABLE[2][5]	AVERAGE[2][3]	**MAXIMUM**[2][4]
Transuranics, ^{226}Ra, ^{227}Ra, ^{230}Th, ^{228}Th, ^{231}Pa, ^{221}Ac, ^{125}I, ^{129}I	20	100	300
Th-Natural, ^{232}Th, ^{90}Sr, ^{223}Ra, ^{224}Ra, ^{232}U, ^{126}I, ^{131}I, ^{133}I	200	1,000	3,000
U-Natural, ^{235}U, ^{238}U, and associated decay products	1,000 α	5,000 α	15,000 α
Beta-Gamma emitters (radionuclides with decay modes other than alpha emission or spontaneous fission) except ^{90}Sr and others noted above.	1,000 β γ	5,000 β γ	15,000 β γ

(1) Where surface contamination by both alpha- and beta-gamma emitting nuclides exists, the limits established for alpha- and beta-gamma emitting nuclides should apply independently.

(2) As used in this table, disintegrations per minute (dpm) means the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.

(3) Measurements of average contaminant should not be averaged over more than 1 square meter. For objects of less surface area, the average should be derived for each object.

(4) The maximum contamination level applies to an area not more than 100 square centimeters (cm^2).

(5) The amount of removable radioactive material per 100 cm^2 of surface area should be determined by wiping that area with dry filter or soft absorbent paper, applying moderate pressure, and assessing the amount of radioactive material on the wipe with an appropriate instrument of known efficiency. When removable contamination on objects of less surface area is determined, the pertinent levels should be reduced proportionately and the entire surface should be wiped.

2.2 Soil Screening Methodology

To accomplish the objective of identifying and removing all discrete radioactive debris in excavated soils, such as luminescent radium dials and small (less than 6 inch) pieces of metal containing or contaminated with ^{226}Ra, ^{232}Th, or ^{238}U, the soil was radiologically scanned on multiple occasions. Two scans were performed manually by the radiological support technician using the audio output from a scintillation detector with a 3 inch by 3 inch sodium iodide crystal activated with thallium (3x3 NaI[Tl]) coupled to a digital rate meter. These scans occurred during the initial excavation and stockpiling of the soil, and as the soil was loaded into the screen plant for physical sizing. If a discrete source was detected by this method, it was removed from the host soil and placed in a secure area for subsequent disposition. A third radiological scan was performed on materials from Pits A, B and C2 by an automated conveyor monitoring system which was mounted over the 6 inch minus soil material exiting the screen plant. By scanning the soil multiple times, it was believed that there was a high probability that all of the discrete radioactive debris had been identified and removed. The purpose of the following is to describe the physical assembly of the automated conveyor monitoring system, its method of calibration, and an estimate of its sensitivity.

2.2.1 Conveyor System Physical Assembly

The automated conveyor monitoring system has been successfully used by CABRERA at several similar sites, specifically the remediation of military base landfills contaminated with depleted uranium. The system employed was a Ludlum Model 4609-3 single channel analyzer coupled to three, independently operated and controlled, 3x3 NaI(Tl) detectors, as shown in Figure 2-1. The three detectors were mounted above the belt, and perpendicular to the direction of belt movement, with a centerline spacing of approximately 6 inches. With the belt loaded with soil, the distance from the top of the soil to the bottom of a detector was approximately 3 to 4 inches. A metal screen was placed across the belt to protect the detectors from any clumps of soil that might otherwise hit the detector and cause false elevated readings. The belt had a width of about 2 ft, and was operated at a speed of approximately 6 ft /second.

When the count rate exceeded a user-defined set point, the automated conveyor monitoring system triggered both a visual and audio alarm. When this occurred, the conveyor operator manually stopped the conveyor, and the suspect soil was manually scanned with a 3x3 NaI(Tl) detector coupled to a digital rate meter for the offending debris. The suspect soil was manually scanned either in the dump truck, or was spread in a thin layer on a polyethylene sheet.

In many cases, the radioactive debris was easily identified and removed for disposition. However, in some instances, no discrete debris was located and it was assumed that the elevated count rate reported by the automated conveyor monitoring system was due to the variation of naturally occurring radionuclides in the soil.

A laptop personal computer (PC) was used to monitor each detector's count rates, input parameters and system alarms. While the system can operate without the PC, use of the PC allowed the system operator to closely observe its performance, and particularly to note the segment count when the system alarmed. As will be discussed, the alarm set points were adjusted to maximize system sensitivity causing the system to false alarm on the natural variation in soil composition. By noting the alarm count, the system operator was able to anticipate whether discrete debris or natural background variation was likely the cause.

2.2.2 System Energy Calibration

The 4609-3 Counter software has a function known as HV Plateau. This function is used to determine the correct operating voltage (or HV) for an individual or group of detectors. The HV Plateau function will take background counts at different HV intervals (set by the user) for each of the three detectors. After the background counts have completed, the software will take source counts on each of the three detectors.

An energy calibration was done by centering the 662 keV peak from a 0.01 uCi ^{137}Cs source into channel 662. This was accomplished by running the HV Plateau function from 500v to 1200v in 25v increments. The lower discriminator was then adjusted to 40, and the upper discriminator was disabled. By unselecting the window mode, the system would be sensitive to all photons with energy above 40 keV.

2.2.3 System Sensitivity

Since a primary calibration source in units of pCi/g was not available, a quantitative distributed or volumetric calibration was not possible. Instead, a qualitative calibration was performed using radioactive debris extracted from the suspect soil. The alarm set points were selected by monitoring the range of count rates reported for each detector over varying types of soil composition, and selecting an alarm set point that was slightly above the normal variation in count rate. The system collected counts in 0.5 second intervals. At a belt speed of 6 ft/second, the linear length of soil being assayed on the belt in any counting interval was therefore about three (3) ft. For soil free of radioactive debris on the belt, the gross count rates per detector over each 0.5 second interval ranged from about 150 to about 250. The alarm set points were set to 290 counts/ 0.5 seconds for the two detectors on the edge of the belt, and to 300 counts /0.5 second for the center detector. This slight difference was to adjust for the more favorable counting geometry of the center detector.

A radium dial and a piece of metal containing thorium which had been extracted from the host soil by one of the scanning processes were used to qualitatively test the reliability and sensitivity of the system. The system was tested multiple times during each day by placing these items on a moving belt loaded with soil and verifying the system would alarm as the items passed beneath each detector. In multiple tests, these items always alarmed the system with 0.5 second counts of between 400 to 600, depending on detector location relative to the item on the belt.

The radium dial had an exposure rate of about 90 microroentgen per hour (µR/h) at 4 inch distance, exclusive of background, and the piece of thorium metal had an exposure rate of 9 µR/h at 4 inch distance, exclusive of background. The background exposure rate was about 7 µR/h, therefore the system was able to reliably alarm at about twice background in this configuration. The counting system was then checked with the radium dial and thorium metal placed on an empty moving belt. In this geometry, the sources were now approximately 7 inches from the detector. In every case, the sources correctly alarmed the system. Finally, the sources were placed on the bottom of the belt, and about 4 inches of soil cover was placed over the sources to attenuate the photon source strength. By this technique, it was believed that the maximum sensitivity of the system was attained using actual debris items collected from the site. Instrument response was reliable over all source configurations.

3.0 CONFIRMATION SURVEY DESIGN

A confirmation survey was planned and conducted for each of the burial pits (Pits A/B, C-1, and C-2) associated with impacted outdoor soil areas. The survey was prepared in accordance with the *Radiological FSP* (Parsons, 2009) and the *Summary of Field Activities* (CABRERA, 2009) which is included in Attachment A of this report. The survey was established with the guidance presented in MARSSIM and following the data quality objective (DQO) process in order to ensure all impacted areas were surveyed with the necessary rigor that corresponds with the contamination potential. The DQO process includes the following seven steps:

Step 1: State the problem

Step 2: Identify the decisions

Step 3: Identify inputs to the decisions

Step 4: Define the study boundaries

Step 5: Develop a decision rule

Step 6: Specify the decisions

Step 7: Optimize the survey design

The following sections provide the design of the confirmation survey including survey planning parameters, instrumentation, measurement and sampling procedures, and the data quality assessments that were implemented.

3.1 Site Release Criteria

As described in Section 1.4 of this report, the release criteria for the SEDA site are as follows:

1) The level of residual radioactivity distinguishable from background at this site results in a total effective dose equivalent to an average member of the critical group of less than 10 mrem/yr as per NYSDEC standards (NYSDEC, 1993); and

2) The level of residual radioactivity which represents an excess lifetime risk, at a point of exposure to an average individual is no greater than between 10^{-4} and 10^{-6}.

The NRC applies a TEDE standard of 25 mrem/yr; the USEPA recommends a TEDE standard of 15 mrem/yr; for this site, a TEDE of 10 mrem/yr (a more restrictive criterion) based on the Technical and Administrative Guidance Memorandum (TAGM) 4003 guide was selected (NYSDEC, 1993).

Levels of residual radioactivity that correspond to the allowable radiation dose are calculated by analysis of various scenarios and pathways through which exposures could be reasonably expected to occur. The *Summary of Field Activities* (CABRERA, 2009) specified derived concentration guideline levels, or DCGLs, which are the concentration of residual radioactivity distinguishable from background that, if uniformly distributed throughout a survey unit, would result in a TEDE to an average member of a critical group equivalent to the allowable dose. These wide-area DCGLs were developed by Argonne National Laboratory (ANL) for use during the license termination effort at SEDA in 2003. These dose-based criteria did not properly account for the residual risk due to residual radioactivity above background at the site. Therefore, for the purposes of satisfying both dose- and risk-based criteria, the data from this survey of the final surfaces of the pits was included as the source term in site-specific dose and risk assessment using the computer code developed by ANL, *Residual Radioactivity (RESRAD), Version 6.5*.

3.2 Identification of Impacted Areas

Three impacted areas were identified during confirmation surveys (Pits A/B, Pit C-1, and C-2). Confirmation surveys of the final surfaces of these pits were based on MARSSIM guidance. Each pit was evaluated as a Class 1 survey unit [SU] in a fashion similar to a standard MARSSIM final status survey, except for a few key differences, which are described in Section 3.5. Burial pit sizes are provided in Table 3-1.

Table 3-1. Land Area Survey Units

IMPACTED OUTDOOR AREAS	IMPACTED AREA SIZE (SQUARE METERS)	MARSSIM RECOMMENDED CLASS 1 SURVEY UNIT LIMITS (SQUARE METERS)
Pit A/B	564	Up to 2,000
Pit C-1 (North Section)	1,341	
Pit C-2 (South Section)	1,562	

3.3 Background Reference Area

Background concentrations of ^{226}Ra and ^{232}Th and other naturally-occurring radionuclides were determined using the surface and subsurface data set from the SEAD-63 project conducted in 2004 (Plexus, 2005). Burial pits were excavated at SEAD-63 with health physics support in a similar fashion to SEAD-12. Unlike SEAD-12, however, no radioactive items were discovered during the SEAD-63 excavation support. Gamma spectroscopy data for ^{228}Ac, ^{214}Bi, Potassium-40 (^{40}K), and ^{234}Th, as well as gross alpha and beta results, were evaluated for statistical outliers and no anomalous data were identified. Therefore, the soils at SEAD-63 were considered to be unimpacted from a radiological perspective and soil sample data from the remediation was used as a background data set. The summary statistics of the evaluated radionuclides are presented in Table 3-2. These values were used to calculate the number of sampling locations as described in Section 3.5.

Table 3-2. SEAD-12 Soil Background Concentrations

RADIONUCLIDE	NUMBER OF MEASUREMENTS	AVERAGE (pCi/g)(1)	STANDARD DEVIATION (pCi/g)	MINIMUM (pCi/g)	MAXIMUM (pCi/g)
^{214}Bi (^{226}Ra)	35	0.6	0.1	0.0	0.8
^{228}Ac (^{232}Th)	35	1.0	0.2	0.0	1.3
^{40}K	35	25.1	2.1	21.0	29.4
^{234}Th	35	1.0	0.4	0.4	2.1
Gross Alpha	35	11.0	2.5	6.2	20.9
Gross Beta	35	26.5	4.9	12.5	42.6

(1) pCi/g = picocuries per gram.

(2) Soil background concentrations presented in this table are from the radiological survey conducted at SEAD-63 (Plexus, 2005).

3.4 Reference System

A reference coordinate system was utilized for confirmation survey measurements and sampling locations. Soil sample locations were referenced to global positioning system (GPS) coordinates (Central New York Planar) obtained using hand-held GPS units.

3.5 Survey Design

The MARSSIM guidelines for sampling design for a FSS were followed in determining the appropriate number of samples to be collected. The initial step is the determination of the relative shift using the following equation:

$$\text{Re}lative\ Shift = \frac{\Delta}{\sigma} = \frac{DCGLw - LBGR}{\sigma}$$

Using the background data for ^{214}Bi and ^{228}Ac shown in Table 3-2, a combined σ was calculated to be 0.16 pCi/g. Using the sum of ratios and unity rule, the $DCGL_W$ is unity, and the lower bound of the grey region is set to 0.5 as a default value. A relative shift of 3.1 results, and from that relative shift, the random measurement probability (P_r) is determined to be 0.983039 from MARSSIM Table 5.2.

The following equation (MARSSIM Equation 5-1) was then used to determine the total number of samples in the survey unit/reference area pair:

$$N = \frac{\left(Z_{1-\alpha} + Z_{1-\beta}\right)^2}{3\left(P_r - 0.5\right)^2}$$

The terms $Z_{1-\alpha}$ and $Z_{1-\beta}$ both reflect the desired Type I and II error rates, both set at 0.05. The total number of samples was then divided by two and increased by a factor of 20%, per MARSSIM recommendations. The overall number of samples required per survey unit was calculated to be 10 samples.

The appropriate number of systematic samples within the pits was calculated to be 10 per 2000 square meters (m^2) Class 1 survey unit, or approximately 1.1 per 2500 square feet (ft^2). This frequency was met by utilizing the sampling points from the chemical sampling activity, which were collected at a frequency of at least 1 sample per 2500 ft^2 from the excavation floor and sidewalls. A grid of the pit areas consisting of 50 ft X 50 ft squares was established prior to the excavation activities and was used to guide sampling frequency. The grid is shown in Figure 3-1. A sample was also collected every 50 linear feet along the perimeter of each of the pits to ensure that area immediately surrounding each of the burial pits was not impacted by remedial activities.

Because of the nature of this remediation, these samples were co-located with chemical sampling locations on the basis of a square sampling grid in accordance with the *Radiological FSP* (Parsons, 2009) and the *Summary of Field Activities* (CABRERA, 2009). While the sample density was calculated in accordance with MARSSIM guidelines, the sample locations were not pre-selected based on a systematic triangular grid as is advised in MARSSIM. Biased samples were collected based on gamma walkover survey (GWS) results as is described in Section 3.6.1.

3.6 Integrated Survey Strategy

Confirmation surveys of open land areas consisted of performing GWS to identify locations of residual contamination and collecting soil samples to be analyzed for the project RCOCs. Additional biased measurements and samples were obtained, as necessary, from locations where scans indicated the potential for residual contamination.

GWS was performed using a Ludlum Model 44-20 three inch by three inch sodium iodide (3x3 NaI) detector coupled to a Ludlum Model 2221 ratemeter. This detector was linked to a GPS receiver/datalogger so that activity measurements could be spatially referenced. Scanning was performed in accordance with MARSSIM protocol by walking straight parallel lines with the detector approximately 10 centimeters (cm) above the ground surface. Survey passes were approximately 0.5 m apart and the scan rate was approximately 0.5 m per second.

Data collected during surface gamma scans in the burial pits was recorded every second along with corresponding easting and northing GPS coordinates. The measurements were plotted and color-coded for visual review and evaluation with the coordinates of the highest measurement identified for possible biased sampling. The average and standard deviation were calculated for each SU to allow evaluation of the data outliers via Z-score. Z-scores represent the number of standard deviations the result lies from the mean, based on following formula:

$$Z - score = \frac{CountRate - Mean}{StdDeviation}$$

All areas exceeding three standard deviations above the average (i.e., Z-score greater than or equal to 3.0), were flagged for further investigation. A biased sample was collected at the location with the maximum Z-score in each burial pit.

Surface soil samples were also collected from burial pit surfaces at locations co-located with chemical sampling locations on a square sampling grid as described in Section 3.5. Following collection, soil samples were maintained under formal chain-of-custody procedures, sent to the offsite laboratory, and analyzed by gamma spectroscopy, with analytical results reported in units of pCi/g. At least 11 samples were collected in each SU.

3.7 Gross Alpha/Beta Concentrations

All samples analyses included gross alpha and gross beta concentrations. Average gross alpha and gross beta concentrations from survey groups are compared with average background concentrations in Table 3-3. Elevated gross alpha or beta concentrations not corresponding with elevated RCOC concentrations could indicate the presence of previously unidentified radionuclides. No SEAD-12 sample group average for gross alpha or gross beta was elevated more than one standard deviation above background values.

Table 3-3. Gross Alpha and Gross Beta Averages

SAMPLE GROUP	NUMBER OF MEASUREMENTS	AVERAGE GROSS ALPHA (pCi/g)	AVERAGE GROSS BETA (pCi/g)
Background	35	11.0	26.5
Overburden	10	10.8	25.1
Disposal	13	13.0	27.3
Pit A	15	10.3	21.5
Pit B	11	10.7	28.6
Pit C-1	22	10.1	22.9
Pit C-2	42	11.0	30.6

4.0 INSTRUMENTATION AND CALIBRATION

4.1 Confirmation Survey Field Instrumentation

Gamma scans were performed in Class 1 land area SUs with a Ludlum Model 44-20 3x3 NaI detector coupled to a Ludlum Model 2221. The 3x3 NaI detector scan MDC for natural thorium is 1.1 pCi/g and the scan MDC for natural radium is 1.5 pCi/g. The scan MDC calculations for each detector are provided in Attachment B.

4.2 Radiological Screening Instrumentation

Radiological screening instrumentation is described in detail in Section 2.0.

4.3 Off-Site Laboratory Instrumentation

FSS soil samples were prepared, submitted, and analyzed at GEL Laboratory LLC in Charleston, South Carolina. Soil samples were analyzed by gamma spectroscopy, allowing for 7 day ingrowth for progeny, and results reported in units of pCi/g. In the approved technical memorandum *Summary of Field Activities* (CABRERA, 2009), ^{226}Ra was to be measured indirectly by the 609 keV gamma emission of its progeny Bismuth-214 (^{214}Bi) with an assumption of 50% equilibrium in soil of the Radon-222 (^{222}Rn) daughter products (due to losses resulting from radon gas emanation) at the time of sealing of the sample. This method was included in the plan after receiving feedback from commercial radiochemistry laboratories that 50% or more of ^{222}Rn daughter products are retained at the time of sealing in soils, especially those soils containing ^{226}Ra contamination in the form of paint chips and small pieces of debris. As a conservative measure in the evaluation of the radiological soil sample data, only 25% equilibrium of ^{222}Rn daughter products was assumed at the time of sealing, and the mean of the ^{214}Bi results and the Lead-214 (^{214}Pb) results was calculated and reported as the ^{226}Ra result. Detailed explanation of derived sample concentration results are presented in footnotes to the Confirmation Survey result tables in Attachment C.

^{232}Th was measured by surrogate analysis of photon emissions from Actinium-228 (^{228}Ac); the second daughter progeny of ^{232}Th under an assumption of secular equilibrium.

5.0 REMEDIAL SUPPORT SURVEY RESULTS

Release surveys were performed as described in Section 2.1. The release surveys performed are summarized on Table 5-1.

Table 5-1. Summary of Equipment Release Survey Results

SURVEY ID	DESCRIPTION	DATE	RANGE OF ACTIVITY MEASUREMENTS		
				FIXED (dpm/100cm^2)	REMOVABLE (dpm/100cm^2)
002	Dump Truck 38495JY	07/21/09	Alpha Beta	0 to 19.7 -741 to -215	0 to 2.7 -41 to 36
003	Flatbed Trailer	07/21/09	Alpha Beta	0 to 14.8 -873 to -586	0 to 2.7 -44 to 22
004	Bulldozer #7106	07/22/09	Alpha Beta	-4.9 to 9.9 -514 to 0	-1.4 to 2.7 -44 to 63
005	Fork Lift MHT00221	07/22/09	Alpha Beta	-4.9 to 29.6 -430 to 311	-1.4 to 1.4 -58 to 17
006	Rolloff # 21	08/03/09	Alpha Beta	N/A; Measurements with GM (44-9) at background levels	N/A
007	M60 Conveyor Belt 18-12-037	08/04/09	Alpha Beta	-9.9 to 14.8 -992 to -263	0 to 4.1 -19 to 47
008	Articulated Dump Truck 006	08/06/09	Alpha Beta	-4.9 to 9.9 -1076 to -227	-1.4 to 2.7 -187 to 72
009	Articulated Dump Truck 007	08/06/09	Alpha Beta	-4.9 to 9.9 -1016 to -251	-1.4 to 1.4 -52 to 47
010	Chieftain 1400 66-03-421	08/10/09	Alpha Beta	-4.9 to 29.6 -1124 to 311	-1.4 to 1.4 -94 to 28
011	Bulldozer #3247	08/11/09	Alpha Beta	0 to 19.7 -861 to 0	0 to 1.4 -47 to 41
012	Front Loader CPT30682	08/11/09	Alpha Beta	4.9 to 14.8 -777 to -382	0 to 2.7 -30 to 41
013	Gas Truck 83-5191	08/11/09	Alpha Beta	-4.9 to 9.9 -1040 to 394	0 to 4.1 -25 to 63
014	Excavator M1-325F	08/11/09	Alpha Beta	-4.9 to 4.9 -1398 to 263	0 to 4.1 -28 to 47
018	Front Loader CPT30682	08/13/09	Alpha Beta	0 to 14.8 -227 to 347	-1.4 to 0 -58 to -3
019	Skid Steer CYC289	08/13/09	Alpha Beta	4.9 to 19.7 -60 to 359	0 to 1.4 -105 to -6

In addition, scans with the 44-9 were at background levels when performed.

This page intentionally left blank

6.0 CONFIRMATION SURVEY RESULTS

A summary of the confirmation survey results are presented below. Complete analytical data are provided in Attachment C.

The impacted areas of SEAD-12 consist of Pits A/B and Pits C-1 and C-2. Pit C-1 and C-2 results were combined into one data set (Pit C) to maintain consistency with the Risk Assessment that was performed at SEAD-12 in 2000. Ten samples were collected from clean overburden material overlying the actual burial pit locations. These clean overburden soils/fill were excavated from the top 2.5 feet at Pit A and B, the top 0.5 feet at Pit C Area 1 north, and the top 3 feet at Pit C Area 2 south and set aside for temporary staging (Parsons, 2009). Because these soils were intermixed during the backfill and restoration and used to backfill Pit A/B, the overburden sample results were added to the Pit A/B evaluation to represent the current condition of the backfilled pit.

Confirmation survey soil sample data from 2009 was combined with previous SEAD-12 radiological sample data from the original baseline risk assessment (BRA) to develop an updated risk/dose model for the site. A detailed description of this assessment is provided in Section 7.0. Analytical data the BRA are included in Attachment C.

Systematic soil sample summary results for the pit surveys are provided in Table 6-1. Biased soil sample summary results for the pit surveys are provided in Table 6-2.

Table 6-1. Burial Pit Systematic Sample Results Summary

^{232}TH SUMMARY						
SURFACE SOIL (0-15 CM) CONCENTRATION						
Impacted Area	Number of Samples Collected	Mean (pCi/g)	Median (pCi/g)	Standard Deviation (pCi/g)	Minimum (pCi/g)	Maximum (pCi/g)
Pits A/B[1]	32	0.76	0.86	0.36	0.00	1.32
Pits C-1/C-2	50	0.79	0.83	0.34	0.00	1.70
^{226}RA SUMMARY						
SURFACE SOIL (0-15 CM) CONCENTRATION						
Impacted Area	Number of Samples Collected	Mean (pCi/g)	Median (pCi/g)	Standard Deviation (pCi/g)	Minimum (pCi/g)	Maximum (pCi/g)
Pits A/B[1]	32	1.16	1.09	0.36	0.73	2.64
Pits C-1/C-2	50	0.98	0.95	0.20	0.69	1.69

Notes: (1) Sample statistics include overburden soil sample results

Table 6-2. Burial Pit Biased Sample Results Summary

^{232}TH SUMMARY						
SURFACE SOIL (0-15 CM) CONCENTRATION						
Impacted Area	Number of Samples Collected	Mean (pCi/g)	Median (pCi/g)	Standard Deviation (pCi/g)	Minimum (pCi/g)	Maximum (pCi/g)
Pits A/B[1]	3	0.97	0.96	0.16	0.81	1.13
Pits C-1/C-2[2]	2	1.12	1.12	0.11	1.04	1.20
^{226}RA SUMMARY						
SURFACE SOIL (0-15 CM) CONCENTRATION						
Impacted Area	Number of Samples Collected	Mean (pCi/g)	Median (pCi/g)	Standard Deviation (pCi/g)	Minimum (pCi/g)	Maximum (pCi/g)
Pits A/B[1]	3	1.01	1.08	0.14	0.85	1.09
Pits C-1/C-2[2]	2	1.07	1.07	0.18	0.94	1.19

Notes: (1) Three biased samples were collected
(2) Two biased samples were collected

Additional discussion of sampling results and statistical tests for each burial pit area in SEAD-12 is provided in the following sections. Soil sample analytical for each of the areas are provided in Attachment C.

Pit A/B

Confirmation survey activities in SEAD-12 Pit A/B included a GWS and collection of 22 systematic surface soil samples. Pit A/B is 564 m^2 in area. Three biased soil samples were collected based on the results of the GWS. Biased sample S12EXSW-N-10-01 was collected at the location of highest gamma activity along the northeast sidewall of Pit A. The GWS is displayed in Figure 6-1. Systematic and biased sample locations are displayed in Figure 6-2.

Pit C

Confirmation survey activities in SEAD-12 Pit C (consisting of Pits C-1 and C-2) included a GWS and collection of 50 systematic surface soil samples. Pit C is 2,903 m^2 in area. Additional biased soil sampling was performed based on the results of the GWS. Biased sample S12EXSW-N-10-01 was collected at the location of highest gamma activity along the southwest sidewall of Pit C-1. Biased sample S12EXSW-E-1-01 was collected at the location of highest gamma activity on the excavation sidewall of Pit C-1. Biased sample S12EXFL-K-3-01 was collected at the location of highest gamma activity on the excavation floor of Pit C-2. GWS results for pits C-1 and C-2 are displayed in Figures 6-3 and 6-5, respectively. Systematic and biased sample locations for pits C-1 and C-2 are displayed in Figures 6-4 and 6-6, respectively.

7.0 DOSE AND RISK ASSESSMENT FOR SEAD-12

Conservative site-specific human health residual dose and risk assessments were performed for the disposal pits A/B and Pit C, located in the Former Weapons Storage Area (SEAD-12) to confirm that the site had been protectively remediated and to verify that the selected remedy had met the response action objectives regarding dose and risk criteria so that the site could be released for use without any radiological restriction. In TAGM Number 4003, the State of NY established a dose criterion of 10 mrem/yr above background to the maximally exposed individual of the general public (NYSDEC, 1993). CERCLA established acceptable target risk range as the risk criteria for the Site. The USEPA defines the CERCLA target risk range as 10^{-6} to 10^{-4} where "the upper boundary of the risk range is not a discrete line at 1×10^{-4}…. A specific risk estimate around 1×10^{-4} may be considered acceptable if justified based on site-specific conditions." (USEPA, 1997).

Confirmation survey results from Pits A/B and C, documented in Section 6.0 of this report, were included as inputs into the dose/risk model. The remaining soil data included in the model were sample results from the BRA that was previously performed for SEAD-12 (Parsons, 2002). Only those soil sample results from the BRA that were determined to represent soils still on site (i.e. were not excavated during the 2009 removal action) were included in the most recent dose/risk assessment. These data are included in Attachment C of this report. These soil sample locations for Pits A/B and C are also displayed in Figures 7-1 and 7-2, respectively. Groundwater, surface water, and sediment sample data from the BRA was reevaluated, if necessary, and included as inputs into the dose/risk model.

During the RI and previous investigations, samples of soil, groundwater, surface water, and sediment were collected. Soil samples were collected from random surface soil locations, biased surface soil locations where contaminants were likely to accumulate, and soil borings and test pit locations. Groundwater samples were collected from groundwater monitoring wells situated throughout the greater SEAD-12 site. Surface water and sediment samples were collected from the drainage ditches throughout SEAD-12. During the Confirmation Survey in 2009, soil samples were collected from the final surfaces of the excavations (including excavation floors, walls, and perimeter benches) and from overburden soils that were used to backfill the Pit A/B excavation.

7.1 Dose and Risk Assessment Methodologies

The dose and risk assessment methodology for radiological constituents is presented in the following subsections of this report:

- Section 7.1.1 provides criteria that were used to evaluate and screen Site data and to determine the radionuclides of potential concern (ROPCs) for each disposal pit;
- Section 7.1.2 defines land use assumptions, receptors, and exposure scenarios used in the assessment;
- Section 7.1.3 presents the guidance that were used to perform the toxicity assessment;

- Section 7.1.4 presents the risk characterization as well as the results of the dose and risk assessments; and
- Section 7.1.5 evaluates the uncertainties associated with the assessments.

7.1.1 Identification of ROPCs

The RI report provides data on the nature and extent of site constituents at the site. These site constituents were designated based on the operational history of each area, including the chemicals and radionuclides known or suspected to have been used at each specific area. In this section of the report, the methodology to select ROPCs is presented. ROPCs differ from site constituents in that the ROPCs are the constituents that have been detected at the site that have gone through an extensive screening process and were then retained for quantitative analysis in the assessment. Four different types of screenings were performed to identify ROPCs for the site. The following sections summarize the screening processes.

(A) Data Reduction

For radiological constituents, any daughter product with a half-life of less than 180 days was not evaluated during this assessment. A six-month cutoff half-life was selected in the radiological dose and risk model. The risk model assumes that these decays products (daughters) are in secular equilibrium with respect to the parent radionuclide. Therefore, their contributions are already incorporated in the dose conversion factor (DCF) and risk coefficients of the parent. Due to this,

- ^{228}Ac (half-life = 6 hr), daughter product of ^{228}Ra, will be evaluated as ^{228}Ra.
- ^{214}Pb (half-life = 27 minutes) and ^{214}Bi (half-life = 20 minutes), daughters of ^{226} Ra, will not be inputted as separate source terms in the model.
- Lead-212 ([^{212}Pb] half-life = 11 hours), Bismuth-212 [^{212}Bi] (half-life = 61 minutes), and Thallium-208 [^{208}Tl] (half-life = 3 minutes), daughters of Thorium-228 (^{228}Th) will not be inputted as a separate source term in the model.
- Thorium-227 ([^{227}Th] half-life = 19 days), ^{223}Ra (half-life = 11 days) and Lead-211 ([^{211}Pb] half-life = 36 min) are daughter products of Actinium-227 (^{227}Ac). All of them will not be inputted as separate source terms in the model.
- ^{234}Th (half-life = 24 days), daughter product of Uranium-238 (^{238}U), will not be inputted as a separate source term.

- The half-life of ^{210}Pb is 22.3 years. After a thorough analysis of the data, of the 20 of 42 samples where ^{210}Pb was detected, the uncertainty associated with those results were usually 75-100% of the result. In the 22 of the 42 samples where ^{210}Pb was not detected, the results averaged 18.42 pCi/g. In these same results, the ^{226}Ra values averaged 1.62 pCi/g. Since ^{226}Ra decays directly to ^{210}Pb, the results would be expected to be much closer to a 1:1 ratio in soils. Gamma spectroscopy does not provide accurate results for ^{210}Pb in soils due to the difficulty in detecting its low energy (49 kev) gamma photon when it decays. The more common and accurate method to analyze for ^{210}Pb is alpha spectroscopy for polonium-210 (^{210}Po), which is a daughter product of ^{210}Pb. Given these reasons, ^{210}Pb sampling results were not used to determine the EPC for ^{210}Pb. The EPC for ^{210}Pb was set equal to that for ^{226}Ra during the dose and risk evaluation for the disposal pits.

(B) Weight-of-Evidence Screening

The weight-of-evidence screening was performed for all radiological constituents that passed the data reduction screening. If the frequency of detection for a chemical in a medium is 5% or less (i.e., a minimum of one detection out of 20 analytical results), generally, the chemical is excluded from further evaluation. This rationale is consistent with USEPA's *RAGS* guidance (USEPA, 1989). Under this screening, radiological constituents that were detected in less than five percent of the samples from a given medium may be artifacts in the data due to sampling, analytical, or other problems, and may not be related to site activities. These constituents were not included in the assessment.

(C) Background Screening

The background screening was performed for all radiological constituents that passed the first two screenings. This screening consisted of comparing the maximum detected concentration against background sample criteria. Background samples were collected during the BRA, and these results are included in Attachment C. If the maximum detected concentration was below background criteria, the site constituent was not considered for risk screening. However, if the site constituent was present at concentrations above background criteria, that site constituent was retained for risk screening.

(D) Risk-Based Screening

Risk-based screening for radionuclides present in soil cannot be performed as there is no soil screening values for radionuclides available in the guidance documents supplied by NYSDEC and USEPA. However, risk-based screening was performed for radiological constituents that are present in the groundwater and surface water. Under the risk screening, the maximum detected concentration of the radionuclide was compared against their corresponding USEPA maximum contaminant level (MCL). Any radionuclide that exceeded the MCL was retained as a ROPC for the Site.

Tables D-1, D-2, D-3, D-4, D-5, D-6, D-7, D-8, and D-9 of Attachment D present the screening process and identify the ROPCs for Disposal Pit A/B surface soil, Disposal Pit A/B surface and subsurface soil, Disposal Pit C surface soil, Disposal Pit C surface and subsurface soil, ground water, onsite surface water, downgradient surface water, onsite sediment and downgradient sediment, respectively.

7.1.2 Exposure Assessment

This section describes the receptors and exposure pathways that were evaluated in the risk assessment. The objectives of the exposure assessment were to estimate the magnitude, frequency, duration and routes of potential human exposures to ROPCs at the Site. Potential receptor groups are identified in the exposure assessment and estimates of exposure or radionuclide intake are calculated based on assumptions regarding exposure pathways and exposure parameters. The following sections of the report summarize the exposure assessment process utilized during this risk assessment.

(A) Current and Future Land Use Scenarios

In July 1995, the Base Realignment and Closure Act (BRAC) Commission voted to recommend closure of SEDA. As part of the BRAC process, a Land Redevelopment Authority produced a Land Reuse Plan. The plan designated various uses for different parcels of SEDA ranging from conservation/recreation to institutional, industrial, and residential. The area which contains SEAD-12 was designated “Conservation/Recreation Area”. In 2005, the Seneca County Industrial Development Agency redesignated land in the greater SEAD-12 area to be used for either conservation/recreational or for institutional/training purposes.

General access to the greater SEAD-12 continues to be restricted by high security fencing, which is maintained by the Army and by a private tenant. Since the redesignation of the land, the SCIDA has leased a portion of the overall SEAD-12 site to the Finger Lakes Communications Group Inc, who currently has established commercial operations in buildings that are located in the northern portion of the site, west northwest of the Disposal Pit excavation sites. For this human health assessment the future land use of SEAD-12 was considered to be conservation and recreation, which are more conservative or restrictive than the current commercial use. Furthermore, as an additional conservative approach, a future residential farmer scenario was also considered to satisfy the State of New York's requirement for evaluation of the site to pre-disposal conditions and the USEPA’s assessment of whether the site is suitable for unrestricted use and unlimited exposures.

(B) Exposure Scenario

An exposure pathway is the physical course a contaminant takes from the source to the exposed receptor. The sources evaluated in this assessment include soil, groundwater, surface water, and sediments.

For radiological constituents, external gamma is an important pathway of exposure and therefore, it was quantified in this evaluation. This pathway is not applicable for chemical constituents.

Humans routinely ingest small amounts of soil or soil-like materials each day primarily as a result of hand-to-mouth activity. As a rule, young children ingest greater quantities of such material than do older children and adults. Soil ingestion is frequently an important pathway of exposure and therefore, was quantified in this evaluation.

Dermal contact is also a likely route of exposure to chemicals in environmental media. Dermal contact with soils could result in the absorption of chemicals through the skin, therefore, dermal absorption of chemicals is usually evaluated for chemicals. However, radiological constituents are typically metals and do not easily pass through the skin. Therefore, dermal contact pathway was not be evaluated for radionuclides.

Inhalation exposure may result from inhaling chemicals which have volatilized, as well as radiological contaminated soil particles. These particles can be emitted into the air either by wind erosion or as a result of mechanical disturbance. The inhalation of radionuclides in soils was evaluated in this human health risk assessment (HHRA).

The groundwater beneath the SEAD-12 is not currently used as a drinking water source for current site workers and there is no current on-site use of groundwater as a potable water source. Additionally, it is unlikely that a groundwater well would be installed for use by future construction workers. Therefore, ingestion of groundwater is not considered a completed pathway for each of these scenarios. For other future receptors, the future plan for all areas of SEDA is to obtain potable water from the existing water supply line. Potable water is supplied to the Depot from a water supply line that passes through the Town of Varick. Water from the town of Varick is obtained from the water treatment plant at the Town of Waterloo. The source of this water is Lake Seneca. It is unlikely that groundwater wells would be installed for future drinking water use since a potable water pipeline exists. The shallow groundwater aquifer at the site is inadequate for both yield and quality. Nonetheless, since this use is not prevented via an institutional control such as a deed restriction, it was assumed that wells would be installed on site for potable water. Therefore, this is considered a complete pathway and data from the on-site wells are used to calculate exposure concentrations. Exposure via ingestion of groundwater was assessed for a future outdoor park worker, a future recreational visitor, and a future residential farmer.

Exposure to surface water and sediment while swimming on-site were considered to be unrealistic pathways of exposure because the depth of drainage ditches is at most only a few inches. As a conservative approach, accidental ingestion of surface water and sediment was considered for only onsite residential receptor scenario. However, exposure to surface water and sediment while wading were evaluated for a downstream receptor in Reeder Creek.

The radon pathway was not included during this evaluation. Radon is a radioactive noble gas that tends to accumulate in enclosed structures. In a Federal Register Notice (NRC, 1994) issued as a result of comments received from a radon workshop, the NRC noted that "radon would not be evaluated when developing release criteria due to: the ubiquitous nature of radon in the general environment, the large uncertainties in the models used to predict radon concentrations; and the inability to distinguish between naturally occurring radon and that which occurs due to licensed activities." It is notable that radon limits are based on concentration and not risk or dose. This difference is due partly to the fact that background radon concentrations are highly variable and can produce risk estimates well above exposure-based limits.

(C) Current and Future Receptor Scenarios

For purposes of this assessment, six types of potentially exposed populations were considered. Under the current land-use scenario, there is one single exposed population: site workers. Under the future land-use scenario, there are three (3) exposed populations: (1) Park workers; (2) Construction workers who work for a short term onsite; and (3) Recreational visitors, who occasionally visit the property. In addition, two other exposed populations were considered: (1) Residential Farmer (for pre-disposal goal evaluation); and (2) Off-site wader. Each of these receptor scenarios is summarized in the following paragraphs.

1. **Current Site Worker** - Current workers at the site spend their time throughout the entire SEDA. Therefore, the current site worker is assumed to visit SEAD-12 infrequently. During these visits, this worker inhales the ambient air at SEAD-12 and may ingest the surface soil there. Based on professional judgment, it was assumed that the current site worker visits SEAD-12 on 20 days per year for 25 years.

   Exposure pathways evaluated for the site worker scenario include:

   - external gamma radiation from radionuclides in the surface soil;
   - incidental ingestion of surface soil; and
   - inhalation of airborne contaminated dust or volatile emissions from surface soil.

2. **Future Construction Worker** - Future construction workers are assumed to spend one year working at SEAD-12, which is a typical duration for a significant construction project. These workers spend each working day at SEAD-12 (5 days/week for 50 weeks). During this time, this worker inhales the ambient air at SEAD-12 and may ingest or dermally contact the soil there. During the course of daily activities, an on-site construction worker will come into contact with the surface and subsurface soils during intrusive activities and may involuntarily ingest soil.

   Exposure pathways evaluated for the construction worker scenario include:

   - external gamma radiation from radionuclides in the soil;

- incidental ingestion of soil; and
- inhalation of airborne contaminated dust or volatile emissions from soil.

3. **Future Park Workers** - The park worker is assumed to work onsite for only 8 months (35 weeks per year) from Spring through Autumn, when the conservation area would be used by recreational visitors. The workday (8 hours/day) and exposure duration (25 years) are the same as other workers. The outdoor worker spends nearly all of his/her time outdoors. This worker inhales the ambient air and ingests groundwater and soil.

   Exposure pathways evaluated for the site worker scenario include:

   - external gamma radiation from radionuclides in the surface soil;
   - incidental ingestion of surface soil;
   - inhalation of airborne contaminated dust or volatile emissions from soil; and
   - ingestion of groundwater.

4. **Future Recreational Visitor (Child)** - While both adults and children may visit the conservation area, potential risks would be expected to be higher for children, due to their higher soil ingestion rates and lower body weights. To be conservative, a child recreational visitor receptor is assessed. The recreational visitor is assumed to reside at the conservation area, such as in a campground, for a consecutive two-week period (24 hours/day, 14 days/year) each year for 5 years. During each visit, the child inhales the ambient air and ingests groundwater and soil.

   Exposure pathways evaluated for the future recreational visitor scenario include:

   - external gamma radiation from radionuclides in the soil;
   - incidental ingestion of soil;
   - inhalation of airborne contaminated dust or volatile emissions from soil; and
   - ingestion of groundwater.

5. **Future Residential Farmer** - The residential farmer is assumed to reside continuously at the site for 30 years. The resident is assumed to be a child for a portion of this duration (0 – 6 years of age) and an adult (18 – 42 years of age) for the balance of its exposure. The resident inhales the ambient air, ingests groundwater, and soil. Exposure to surface water and sediment while swimming on-site were considered to be unrealistic pathways of exposure because the depth of drainage ditches is at most only a few inches. Therefore, the resident may ingest surface water and sediment accidentally.

The onsite resident is assumed to spend 1 day every other day during the summer time near the surface water bodies present at the site. The resident is assumed to ingest 0.05 liters/day of water (USEPA, 2011) while being exposed to surface water pathway (incidental ingestion). The resident is also assumed to ingest 12 milligrams (mg) of sediment (10% of soil ingestion rate) while being exposed to contaminated sediment exposure pathway.

Exposure pathways evaluated for the residential scenario include the following:

- external gamma radiation from radionuclides in the soil;
- incidental ingestion of soil;
- inhalation of airborne contaminated dust or volatile emissions from soil;
- ingestion of foods from crops grown in the contaminated soil;
- ingestion of milk from livestock raised in the contaminated area;
- ingestion of fish from a nearby pond contaminated by water percolated through the contaminated area;
- ingestion of meat from livestock raised in the contaminated area;
- incidental ingestion of surface water;
- incidental ingestion of sediment; and
- ingestion of groundwater.

6. **Off-Site Wader** - The off-site wader is assumed to be a child, who periodically wades in Reeder Creek (downgradient from SEAD-12 and SEDA) over a 5-year period. It is assumed that the child visits the creek once per week in the summer (estimated to be 14 weeks). The off-site wader is exposed to surface water and sediment.

Attachment E presents the assigned values for exposure parameters related to each receptor scenario, and the applicable sources where the values were obtained.

(D) Determination of Source Term

Following the collection and validation of the radiological data, subsets of this collected data were utilized to establish the exposure point concentrations (EPCs), or the estimate of the constituent concentration a receptor is likely to come in contact with over the duration of exposure. To calculate a cancer risk, an EPC or an estimate must be made of the chemical concentration in the environmental medium to which an individual may be exposed. As a conservative approach, EPCs for various media were determined by calculating the 95% upper confidence limit (UCL) of the mean following the procedures presented in USEPA's 2002 guidance document, *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites (OSWER 9285.6-10*) (USEPA, 2002). ProUCL program version 4.0 was utilized during the determination of appropriate UCL. When the percentage of non-detected samples in a data set is high, especially when multiple detection limits might be present, it is very difficult to reliably determine the distribution of the data set. In such situations, it is preferable to use a non-parametric method to determine the 95% UCL. The 95% UCL was used as the EPC, except in cases where the maximum detected value was less than the 95% UCL. In these cases, the maximum detected value was used as the EPC. The EPC was adjusted further by subtracting the background concentration for each radionuclide. The non-zero EPCs for each ROPC present in Disposal Pit A/B surface soil, Disposal Pit A/B surface and subsurface soil, Disposal Pit C surface soil, Disposal Pit C surface and subsurface soil, ground water, onsite surface water, downgradient surface water, onsite sediment and downgradient sediment are presented in Tables 7-1 and 7-2. These tables are also presented in greater detail in Attachment D of this report.

Table 7-1. Exposure Point Concentrations for Soil Radionuclides of Potential Concern

Radionuclides		Detect?	FOD	Concentration		Background Concentration	Dist[a]	UCL_{95}	EPC[b]
Parent	Daughter			Max	Min

7.1.3 Toxicity Assessment for ROPCs

RESRAD 6.5 utilizes Federal Guidance Report (FGR) No 11 and 12 DCFs for determining radiological dose assessment to various receptors present at the site. Those DCFs are based on International Commission on Radiological Protection (ICRP) 30 publications. To estimate radiological risk, the RESRAD code utilizes FGR 13 risk coefficient values. The risk coefficients derived in FGR 13 are based on methods and models that take into account the age- and gender-dependence of radionuclide intake, metabolism, dosimetry, radiogenic risk, and competing causes of death in estimating the cancer risk from low-level exposures to radionuclides in the environment. These risk co-efficient slope factors are presented in units of risk per pCi (internal pathways) or risk per year per pCi/g (external pathways). Attachment F provides the risk coefficients for each ROPC present at the site.

7.1.4 Risk Characterization

Risk characterization integrates the findings of the exposure assessment and toxicity assessment to estimate the likelihood that a receptor may experience an adverse effect as the result of exposure to ROPCs (USEPA, 1989). For radionuclides, incremental lifetime cancer risks (ILCRs), or the increased lifetime probability of cancer, and radiological doses were calculated for each receptor scenario.

The resulting ILCRs were compared to the range specified in the *National Oil and Hazardous Substances Contingency Plan* (USEPA, 1990) of 10^{-6} to 10^{-4}, or 1 in 1 million to 1 in 10,000 persons developing cancer. ILCRs below 10^{-6} are considered acceptable risks. ILCRs above 10^{-4} are considered unacceptable risks. Risks between 10^{-6} and 10^{-4} are generally referred to as the "acceptable risk range". Radiological dose estimates in mrem/yr also were compared against dose-based goals. State of New York identified a dose limit criterion of 10 mrem/yr. The radiological dose results for each receptor scenario were compared with respect to 10 mrem/yr dose criterion.

Attachment G presents output radiological dose and risk assessment summary reports for each exposure scenario. Table 7-1 presented the summary of maximum radiological dose and risk assessments in a 1000 year period under current site worker, future construction worker, future park worker, future recreational visitor, and future resident, respectively. The results showed that the maximum doses for ROPCs occurred at year 0 or at year 1000. The results of radiological risk and dose assessments showed that the maximum risk and dose did not exceed their corresponding acceptable risk and dose criteria for both current and future receptor scenarios. Therefore, no further radiological remediation is recommended based on the results of this risk assessment.

Table 7-3. Results of Maximum Dose and Risk Assessments for Various Receptors

Disposal Pit	Exposure Media	Current Site Worker		Future Construction Worker		Future Park Worker		Future Recreational Visitor		Future Residential Farmer

[1] Units of Dose is mrem/yr [2] N/A = not applicable for this receptor scenario

Note: Residual dose and risk assessment was also performed for a wader due to exposure to offsite surface water and sediment pathways. The wader will be exposed to less than 1 mrem/yr above background dose and 2E-9 level of risk.

7.1.5 Uncertainty Assessment

The methodology used in this risk assessment is consistent with USEPA risk assessment guidance documents. However, due to many assumptions that must be made about exposure and toxicity, there is uncertainty associated with every risk assessment. Assumptions built into the risk assessment in general, overestimate rather than underestimate potential risks, but occasionally can result in underestimating risk. In the following section, an evaluation is presented of the sources of uncertainty in the assessments and the relative influence of these sources on the results of the evaluation. The results of the assessments are presented in terms of the potential for adverse effects based upon a number of conservative assumptions. The tendency to be conservative is an effort toward protecting health. Uncertainty can be found at all phases in the risk assessment: in the analytical data, the exposure assessment, the toxicity assessment, and the risk characterization. Where uncertainty does exist, the BRA uses conservative assumptions to ensure that the outcome will be protective.

(A) Uncertainties in Analytical Data

Uncertainty is introduced to the assessment when sample locations are selected and when samples are collected and analyzed. Based on the information regarding historical site operations, and gamma walkover surveys, samples were collected from areas of potential sources and releases. As a result, there is a conservative bias for EPC and associated risk estimates.

In the assessment, the long-term exposure concentrations were upper estimates of site concentrations (e.g., maximum detect or 95% UCL) rather than the sample mean to characterize each disposal pits. The uncertainty from a relatively small sample size (less than 5) requires a greater amount of conservatism during the estimation of mean, while a large sample size requires less conservatism during the estimation of mean. For either case, a conservative bias to overestimate potential exposure has been incorporated into the risk estimates. The uncertainty associated with the statistical analysis of environmental data is low, with little introduction of bias.

(B) Uncertainties in Exposure Assessment

Exposure assessment may introduce considerable uncertainty in the risk assessment process. Exposure assumptions are based on speculation regarding potential land use, assumptions concerning contaminant fate and transport, and receptor behavior. The uncertainty associated with the exposure assumptions used in the risk assessment is low to moderate, and most likely overestimates the actual risks.

The exposure scenarios, receptors, exposure pathways, exposure parameters, and media included in the assessment were selected to conservatively represent a variety of exposure scenarios that could occur at the Site area. The site is zoned as industrial. Therefore, six different types of receptors were considered for the current and future RME receptors for the sites. Dose and risk assessments were also performed for a very conservative residential receptor scenario.

Assumptions regarding uniform contamination across the actual size of each exposure unit with no soil cover are likely produce conservative dose and risk results. The assessment also assumed that the receptors will be exposed equally at each location within each disposal pit. The Site-wide RI report showed that the nature and extent of radiological contamination cover a small area (which would lower dose estimates) and may only reasonably expose a subset of individuals (e.g., utility workers) (Parsons, 2002). Therefore, equal exposures at each location are quite unlikely.

Exposure parameters were selected to provide a conservative, yet reasonable, estimate of potential risks to each receptor. Site-specific measurements and data were used, as appropriate, to describe site conditions as accurately as possible. Where site-specific data were not available, parameter values were chosen to provide reasonably conservative estimates of risk, or standard default values recommended by the *Exposure Factors Handbook* (USEPA, 2011) were used. Intake parameters for the various exposure pathways (soil ingestion, dermal contact, inhalation, external gamma) were conservatively assumed to be upper bound estimates to take account the uncertainty associated with those parameters.

The risk from gamma radiation is dependent on the source surface area and thickness. Slope factors for external gamma radiation assume that the source is a semi-infinite slab. This geometry may represent actual conditions resulting in an overestimate of risk. The radionuclide concentrations are spotty in nature. However, during this assessment, radionuclides are assumed to be uniformly contaminated across the thickness of the contaminated zone. This assumption resulted in an overestimation of dose and risk.

(C) Uncertainties Related to Toxicity Information

Although USEPA approved toxicity values were used for the HHRA, a significant amount of uncertainty may surround these values. Identification of the sources of this uncertainty enables the risk assessor to establish the degree of confidence associated with the toxicity measures.

Uncertainty is inherent within the toxicity assessment and is primarily due to differences in study design, species, sex, routes of exposure, or dose-response relationships. A major source of uncertainty involves using toxicity values based on experimental studies that substantially differ from typical human exposure scenarios. The derivation of the toxicity values must take into account such differences as 1) using dose-response information from animal studies to predict effects in humans, 2) extrapolating dose-response information from high-dose studies to predict adverse health effects from low doses, 3) using data from short-term studies to predict chronic effects, and 4) extrapolating from uniform animal populations to variable human populations.

The cancer slope factors in particular are based on studies that may differ greatly from realistic situations. Experimental cancer bioassays typically expose animals to very high levels of chemicals (i.e., the maximum tolerated dose) for their entire lifetime. After appropriate studies have been identified, the slope factor is calculated as the 95% UCL of the slope of the dose-response curve. This introduces conservatism into the risk assessment. In addition, carcinogens are assumed to be human carcinogens regardless of USEPA's weight-of-evidence classification.

Lifetime cancer risk estimates are provided for exposure to constituents and are compared to the CERCLA target risk range of 10^{-6} to 10^{-4}. Radiological risk slope factors have been developed primarily using data from groups such as the Japanese atomic bomb survivors. These individuals received large doses of radiation over a short period of time. By contrast, potential receptors in this assessment receive relatively small radiological doses over a long period of time. Although cancerous effects have only been detected at doses several orders of magnitude larger than those estimated at the Site, it is assumed that the slope factors apply to both large and small radiological doses. Non-radiological cancer slope factors (CSFs) are developed mostly from animal studies, and slope factors for radionuclides and non-radiological incorporate several differences that may result in incompatibility. USEPA, therefore, acknowledges a large (undefined) uncertainty in risk estimates.

A series of reports published by the National Research Council's Committee on the Biological Effects of Ionizing Radiation (BEIR) lists additional uncertainties resulting from the use of CSFs for radionuclides. BEIR reports point out that cancer risks from exposure to radionuclides at environmental levels (typical background radiation produces approximately 300 mrem/yr) are very difficult to distinguish from background cancer rates. In addition, the calculation of CSFs is based on radium dial painter studies, atomic bomb survivor studies, etc., each considering doses many orders of magnitude higher than those received at environmental levels. The applicability of the linear no-threshold model has been debated by many professional societies. However, the linear no-threshold model (i.e., assuming risk is linear with exposure and is possible for even the smallest doses) has been adopted by all relevant United States regulating agencies. Using this model, risks at environmental levels are calculated even at dose levels a small fraction of background.

An additional area of uncertainty is exposure to multiple chemicals. Toxicological criteria are developed for individual chemicals. Potential interactions between chemicals could occur, leading to uncertainty in the risk estimates for multiple-chemical exposures. The risk assessment assumes that toxicity is additive across chemicals. This assumption would underestimate risk for chemicals that are synergistic or potentiometric with regard to toxicity, and overestimate risk for chemicals that are antagonistic with regard to toxicity. In addition, if chemical toxicological mechanisms differ or affect different organ systems, the assumption of additivity is conservative.

In October 1999, Washington State University, under contract to the USACE, published a report titled *Determination of the In Vitro Dissolution Rates of Selected Radionuclides in Soils* and Subsequent ICRP 30 Solubility Classification for Dosimetry that may be used to support radiological dose and risk estimates. In vitro dissolution rates are broken into three classes: D, W and Y, with Class D being the most soluble and Class Y being the least soluble. RESRAD conservatively assumes by default that all radionuclides are present as Class Y because Class Y would cause the calculated dose and risk estimates to be higher.

(D) Uncertainties in Risk Characterization

Uncertainties in the EPC estimation, exposure assessment, and toxicity assessment affect the degree of confidence in the assessment of risks. If the uncertainty in the EPC is low and the risk-driving chemical is a known human carcinogen (Class A), the corresponding uncertainty in the risk characterization is considered low. For cases where the EPC uncertainty is low, but the toxicity criteria are more uncertain, the corresponding uncertainty is considered low to moderate. Finally, if the EPC uncertainty is moderate to high, then the corresponding uncertainty in the risk characterization is considered moderate to high.

Combining the upper bound exposure assumptions, upper bound toxicity assumptions, and upper bound exposure concentrations, as in the RME approach, is a conservative approach typically utilized in risk assessment. This approach assumes, for example, that individuals who are most sensitive to the potential cancer effects of a chemical will also have a breathing rate and exposure duration (e.g., time at one residence) that exceeds most of the population. With numerous upper bound exposure assumptions combined, the risk is typically overestimated for the population. The corollary is that virtually all potentially exposed individuals will have a much lower level of potential risk than that which is estimated by the conservative assumptions employed in this assessment.

8.0 QUALITY ASSURANCE / QUALITY CONTROL

Only qualified and trained personnel operated the equipment and instrumentation used in the remediation and confirmation survey field activities. Personnel were trained in the technical, quality control (QC), and health and safety aspects of the project, as well as in the calibration, maintenance, and operating procedures for their assigned equipment.

8.1 Instrumentation Requirements

The CABRERA Project Health Physicist (HP) was responsible for determining the instrumentation required to complete the requirements of this confirmation survey. Only instrumentation approved by the CABRERA Project HP was used to collect radiological data. The CABRERA Project HP was responsible for ensuring individuals were appropriately trained to use project instrumentation and other equipment, and that instrumentation met the required detection sensitivities. Instrumentation were operated in accordance with either a written procedure or manufacturers' manual, as determined by the CABRERA Project HP. The procedure and/or manual provided guidance to field personnel on the proper use and limitations of the instrument.

Instrument QC checks were performed as presented in the project Work Plan. Instruments used to obtain radiological data, including GPS equipment, were inspected for physical damage, current calibration and erroneous readings in accordance with applicable procedures and/or protocols. The individual performing these tasks documented the results in accordance with the associated instrument procedure and/or protocols. Instrumentation not meeting the specified requirements of calibration, inspection, or response check would have been removed from operation. All instruments met these QC requirements during field activities, and thus, none were removed from service.

8.1.1 Calibration Requirements

Instruments used during the confirmation survey had current calibration and maintenance records on site for review and inspection. The records included the following:

- name of the equipment
- equipment identification (model and serial number)
- manufacturer
- date of calibration
- calibration due date

Instrumentation was maintained and calibrated to manufacturers' specifications to ensure that required traceability, sensitivity, accuracy and precision of the equipment/instruments was maintained. Instruments were under current calibration. The calibration records for the instruments used in support of this FSS are presented in Attachment H.

8.1.2 Instrument QC Source Checks

Prior to daily use, project instrumentation was QC checked by comparing instrument response to a benchmark response. Prior to the commencement of field operations, site reference locations were selected for performance of these checks; subsequent QC checks were performed at these locations. QC source checks consisted of a one-minute integrated count with the designated source positioned in a reproducible geometry performed at the reference location. Prior to the start of initial surveys, this procedure was repeated at least ten times to establish average instrument response. Instrument responses to designated QC check sources were recorded and evaluated against the average established at the start of the field activities. An acceptance criterion of ± 20% was required for direct measurement detectors. The QC results for the instruments used in support this FSS are presented in Attachment H.

9.0 CONCLUSIONS

Remedial activities were performed at SEAD-12 within burial pits A/B, C-1, and C-2 to remove multiple radioactive military items, including dials containing radium and presumed facsimiles of classified system components containing thorium. A confirmation survey, including gamma walkover surveys and systematic/biased soil sampling, was performed on the final surfaces of the excavated pits. This soil sample data was compiled, combined with applicable soil sample data collected as a part of the BRA performed in 2001 (Parsons, 2002), and these data were included as inputs into a residual radiological dose and risk assessment. This dose and risk assessment was performed using the dose modeling computer code RESRAD to determine the following:

1) The level of residual radioactivity distinguishable from background at this site would result in a total effective dose equivalent to an average member of the critical group of 10 mrem/yr or less as per NYSDEC standards; and

2) The level of residual radioactivity represents an excess lifetime risk of cancer, at a point of exposure, to an average individual no greater than between 10^{-4} and 10^{-6}.

As described in detail in Section 7.0, the total radiological dose and risk for the residential farmer receptor scenario in Pit A/B are 1.0 mrem/yr and an excess risk of 1.1E-5, respectively. The total radiological dose and risk for the residential farmer receptor scenario in Pit C are 1.9 mrem/yr and an excess risk of 4.1E-5, respectively. These calculated radiological dose and risk values comply with the requirements listed in 1) and 2) above. Therefore, it is concluded that SEAD-12 meets the criteria for unrestricted release.

Summary of Field Activities

SEAD-12 Excavation
Seneca Army Depot Activity, Romulus, New York

1.0 INTRODUCTION

Cabrera Services, Inc. (CABRERA) is contracted with Parsons Infrastructure and Technology, Inc. (Parsons) to provide health physics support services during the excavation of three previously identified areas at SEAD-12, Seneca Army Depot Activity in Romulus, New York. The excavations, at Disposal Pits A/B and C, were subject to surface gamma walkover and geophysical surveys, test-pitting, and soil sampling during the Remedial Investigation (RI) performed at the site in the late 1990s. The RI concluded that no further action at the site was warranted. In 2008, the Army decided to move forward with an effort to fully remove all military items identified in the test pits prior to leasing the property to a private tenant. The excavation began on 13 July 2009.

Parsons prepared a project Work Plan (Parsons 2009) under the assumption that the excavation would proceed in a manner similar to that performed by Plexus (with support from Cabrera) at SEAD-63 in 2004 (Plexus 2005). The desired disposition of the excavated materials was either final disposal at a local solid waste landfill or reuse as backfill materials.

The excavation has resulted in the discovery of multiple radioactive military items, including dials containing radium and/or thorium, and presumed facsimiles of classified weapons system components containing thorium. Some limited contamination of soils, consisting of small dial fragments, has been observed. Based on the change in the underlying assumptions of the current project work plan, additional documentation regarding the project approach is required.

The scope of this memorandum is to document the radiological screening approach, the capabilities and limitations of debris and soil screening surveys, discuss the applicable and appropriate derived concentration guideline levels (DCGLs) used to demonstrate compliance with release criteria, and present the sampling plan for confirmation sampling of waste soils prior to disposal and the final excavations prior to backfill.

2.0 RADIOLOGICAL SCREENING METHODOLOGY

2.1 Surface Baseline Survey

To document the pre-excavation conditions of the ground surfaces at the presumed excavation pit footprints and planned support areas, a Trimble global positioning system (GPS)-enabled gamma walkover survey (GWS) was performed using a Ludlum 44-20 3”x3” sodium iodide (NaI) gamma scintillation detector. The data were logged and uploaded to geographical information system (GIS) mapping software and statistically evaluated to identify any outliers or anomalies. The footprints of Pit A, Pit B, Pit C-2, the sorting/segregation area, and the background area were scanning. Logged scans at Pit C-1 were not performed prior to excavation; due to some initial setup problems with the GPS unit, only qualitative data were collected from the C-1 footprint. One point of interest (POI) with above-background radiation levels was identified in the C-1 footprint. Further investigation found a small piece of brown sandstone-like material for which subsequent laboratory analyses identified elevated levels of radionuclides associated with both the natural uranium and thorium decay series.

2.2 Initial Excavation Screening

Excavation began at Pit B. Material was transferred from the track excavator to an end dump truck, which drove to the staging area where material was placed on a plastic liner. A bulldozer was used to evenly spread the excavated material to facilitate gamma scanning measurements. Scanning was performed using a Ludlum 44-20; the technician utilized the audio response to identify locations with elevated readings, which were flagged. Following the scan, the technician returned to the flagged locations to investigate and manually remove the radioactive source. If needed, the bulldozer was used to assist in digging out any large objects. Radioactive sources were placed into B-12 waste containers.

The scanning, flagging, and removal process continued on the excavated material piles during the excavation of all pits. The thickness of material placed on the waste pile at any one time was limited to 6 inches; however due to the volume of material removed (particularly from Pit A) lifts may have exceeded 6 inches.

The minimum detectable concentration (MDC) of the Ludlum 44-20 used in the gamma scanning was calculated using the methodology from NUREG-1507 (NRC 1998). Based on the initial identification of dials with radium luminescent paint, the primary radionuclide of concern identified is radium-226 (^{226}Ra). The detector response to ^{226}Ra in equilibrium with its progeny with varying thicknesses of soil cover was modeled. Assuming no soil cover, a MDC of 1.5 picocuries per gram (pCi/g) is achievable. With a soil cover of 3 inches, the MDC is modeled to be 4.1 pCi/g.

2.3 Secondary Excavation Screening

To accomplish the objective of sorting the excavated materials by size, a screen plant was brought onsite. Excavated material was sorted into less than 6-inch diameter (i.e., mostly soils) and greater than 6-inch diameter streams. Additional gamma scanning was performed on the lift removed from the excavated material pile prior to loading that material into the screen plant. In addition, a gamma detection system was installed on the less than 6-inch diameter output conveyor of the plant to allow for an additional check on the previous scans. The alarm of the conveyor detection system was set at slightly above natural background to allow for the most conservative approach in screening the material. When the alarm sounded, the screen plant was shut down, and manual screening was performed on the material to identify the source.

The screen plant detector system consisted of three Ludlum 44-20 3”x3” NaI detectors connected to a Ludlum 4609 multi-detector control box. The detectors were suspended approximately 3 inches over the soil on the output conveyor. At the operating speed of the conveyor (6 feet per second), each individual detector has a modeled MDC of 3.0 pCi/g with no soil cover. Under a soil cover of 3 inches (the maximum observed soil thickness on the conveyor), the modeled MDC is 8.2 pCi/g. However, the intent of the detector system is to identify discrete sources that may have been missed during the previous scans, and to not assess low-level distributed activity in the soils. The waste soils are subject to additional soil sampling as described in Section 3.1.

2.4 Radionuclide Identification

After discovery of the radioactive components, three samples of material and four smear samples with activity detected above background were sent to GEL Laboratory in Charleston, South Carolina, for quick screen gamma spectroscopy analyses. The results were used to confirm the

suspected radionuclides of concern (ROCs) for this project. Table 2-1 lists the samples and detected results.

Table 2-1. Gamma Spectroscopy Quick Screen Results

SAMPLE ID	MATERIAL	DETECTED RADIONUCLIDES (1)
S12DS01; S12WS04	Brown sandstone material	Elevated natural uranium (^{238}U) progeny: ^{214}Bi (250 pCi/g); ^{214}Pb (249 pCi/g); ^{210}Pb (243 pCi/g) Elevated natural thorium (^{232}Th) progeny: ^{228}Ac (408 pCi/g); ^{212}Bi (258 pCi/g); ^{212}Pb (368 pCi/g); ^{208}Tl (157 pCi/g)
S12DS02; S12WS03	White metal piece	Elevated natural thorium (^{232}Th) progeny: ^{228}Ac (1,080 pCi/g); ^{212}Bi (685 pCi/g); ^{212}Pb (1,120 pCi/g); ^{208}Tl (403 pCi/g)
S12DS03; S12WS02	Clump of mud with paint/metal flakes	Radium (^{226}Ra) progeny: ^{214}Bi (2,080 pCi/g); ^{214}Pb (1,470 pCi/g); ^{210}Pb (1,960 pCi/g)
S12WS01	Smear of excavated component	No radionuclides reported as detected.

(1) Bi = bismuth; Pb = lead; Ac = actinium; Tl = thallium.

A discussion of the samples with reported detections appears below:

- S12DS01: This sample consisted of the material identified during the initial baseline scanning survey of the surface footprint Pit C-2. The location was flagged and excavated using shovels - the source material was found approximately six inches below the ground surface. Measurements returned to background levels following its removal.

  Based on the detection of radionuclides associated with both the naturally-occurring uranium and thorium decay series, the material is assumed to be unprocessed. One historical mission of SEDA was the storage of valuable ores, including pitchblende ore (in SEAD-48) and columbite ore (in SEAD-XXX). With the rock's location in the surface soil it is unlikely it was intentionally placed in the area for burial. No additional similar material was found over the course of the excavation and/or screening process.

- S12DS02: This sample was collected from the vicinity several items that had a large white-colored light metal sleeve with above-background radiation levels, and appears to be the same type of material. The results indicate the presence of natural thorium (^{232}Th) progeny. The items themselves were not identified, but thorium alloys with aluminum, magnesium, and other light metals are common in aircraft parts and other components that must maintain structural integrity in high temperatures.

- S12DS03: This sample consisted of a clump of clay with small pieces of metal or paint, apparently from a damaged radium dial or gauge. The detection of three progeny of radium-226 (^{226}Ra) without detections of uranium decay series progeny above ^{226}Ra, such as thorium-234 (^{234}Th) confirm the presence of radium.

To further assist in identification of the radionuclides present in components or debris, a Canberra Inspector 1000 portable multi-channel analyzer (MCA) was brought onsite. The

Inspector 1000 system consisted of a NaI-based detector to allow for quick identification of detected gamma energies. Measurements were conducted on excavated debris using the manufacturer's recommendations. A cesium-137 (^{137}Cs) source was used during the measurement to provide a reference energy (661 keV) to determine potential spectral shift due to temperature or other fluctuations in operating parameters.

3.0 SAMPLING DESIGN

The following subsections describe the requirements for confirmation and final sampling of the excavated soils as well as the excavated pits. The sample protocol was developed using the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM; NRC 2000).

3.1 Radionuclides of Concern

Based on the results of the quick screen gamma spectroscopy results as well as the onsite screening with the MCA, the primary ROCs for this project are ^{226}Ra and ^{232}Th in equilibrium with progeny. To facilitate analytical requirements, ^{226}Ra will be measured indirectly by the 609 keV gamma emission of its progeny bismuth-214 (^{214}Bi) with an assumption of 50% equilibrium in soil (due to losses resulting from radon gas emanation). Similarly, ^{232}Th will be measured by the 911 keV gamma emission of its progeny actinium-228 (^{228}Ac) under an assumption of 100% equilibrium. Both analyses were performed by gamma spectroscopy, with a required MDC of 0.2 pCi/g.

Background concentrations of ^{226}Ra and ^{232}Th and other naturally-occurring radionuclides were determined using the surface and subsurface data set from the SEAD-63 project conducted in 2004 (Plexus 2005). Unlike SEAD-12, no radioactive items were discovered during the SEAD-63 excavation support. Gamma spectroscopy data for ^{228}Ac, ^{214}Bi, potassium-40 (^{40}K), and thorium-234 (^{234}Th), as well as gross alpha and beta results, were evaluated for statistical outliers and no anomalous data were identified. Therefore, the soils data from SEAD-63 is considered appropriate to use as a background data set. The summary statistics of the evaluated radionuclides are presented in Table 3-1.

Table 3-1. SEAD-12 Soil Background Concentrations

RADIONUCLIDE	NUMBER OF MEASUREMENTS	AVERAGE (pCi/g)(1)	STANDARD DEVIATION (pCi/g)	MINIMUM (pCi/g)	MAXIMUM (pCi/g)
^{214}Bi (^{226}Ra)	35	0.6	0.1	0.0	0.8
^{228}Ac (^{232}Th)	35	1.0	0.2	0.0	1.3
^{40}K	35	25.1	2.1	21.0	29.4
^{234}Th	35	1.0	0.4	0.4	2.1
Gross Alpha	35	11.0	2.5	6.2	20.9
Gross Beta	35	26.5	4.9	12.5	42.6

(1) pCi/g = picocuries per gram.

3.2 Release Criteria

Wide-area derived concentration guideline levels ($DCGL_W$s) were developed by Argonne National Laboratory (ANL) for use during the license termination effort at SEDA in 2003. The License Termination Plan (LTP; ANL 2003) was reviewed and approved by Nuclear Regulatory Commission (NRC) Region I for use in evaluating residual radioactivity levels across SEDA. Pursuant to NRC review comments, a probabilistic analysis of input parameters for the dose modeling code RESRAD was performed. The final $DCGL_W$s correspond to a total effective dose equivalent (TEDE) of 10 millirem per year (mrem/yr). The LTP DCGLs were adopted for use at the SEAD-48 site, and are applicable and appropriate for the SEAD-12 excavation site.

Table 3-2. Soil Release Criteria

RADIONUCLIDE	$DCGL_W$ (pCi/g)[1]
^{226}Ra	1.7
^{232}Th	1.5

To determine compliance with the overall dose limit, the sum of ratios (SOR) is applied to the analytical results using the following equation:

$$SOR_{DCGL_W} = \left(\frac{Conc_{Ra-226}}{DCGL_{Ra-226}} + \frac{Conc_{Th-232}}{DCGL_{Th-232}} \right)$$

An SOR greater than 1 for a given sample indicates the sample results exceed the dose limit.

3.3 Waste Confirmation Sampling

To verify that waste soils do not exceed the release criteria specified in Section 3.2, soil samples were collected. At the time of sampling, the waste soils had been subject to three gamma scanning surveys. In the absence of any positive scanning results, the soil was expected to have no residual contamination present, or residual contamination present at a small fraction of the DCGLs. These conditions meet the definition of a Class 3 survey unit, per MARSSIM Section 2.2. However, as MARSSIM does not define specific sampling requirements for Class 3 survey units, the waste soil was conservatively considered to be a Class 2 survey unit to facilitate the sampling design.

The MARSSIM guidelines for sampling design for a final status survey (FSS) utilizing the Wilcoxon Rank Sum (WRS) test were followed in determining the appropriate number of samples to be collected. The initial step is the determination of the relative shift using the following equation:

$$\text{Relative Shift} = \frac{\Delta}{\sigma} = \frac{DCGLw - LBGR}{\sigma}$$

Using the background data for ^{214}Bi and ^{228}Ac shown in Table 3-1, a combined σ was calculated to be 0.16 pCi/g. Using the SOR and unity rule, the $DCGL_W$ is unity, and the lower bound of the grey region (LBGR) is set to 0.5 as a default value. A relative shift of 3.1 results, and from that

relative shift, the random measurement probability (P_r) is determined to be 0.983039 from MARSSIM Table 5.2.

The following equation (MARSSIM Equation 5-1) was then used to determine the total number of samples in the survey unit/reference area pair:

$$N = \frac{\left(Z_{1-\alpha} + Z_{1-\beta}\right)^2}{3\left(P_r - 0.5\right)^2}$$

The terms $Z_{1-\alpha}$ and $Z_{1-\beta}$ both reflect the desired Type I and II error rates, both set at 0.05. The total number of samples was then divided by two and increased by a factor of 20%, per MARSSIM recommendations. The overall number of samples required per survey unit was calculated to be 10 samples.

To determine the sampling frequency, the maximum surface area of 10,000 square meters (m^2) for a Class 2 survey unit was considered. Assuming a surface soil thickness of 6", the total volume of soil represented by a Class 2 survey unit is equal to 1524 cubic meters (m^3), or 1993 cubic yards (cy). Using the required number of samples calculated above, the sampling frequency is calculated to be 1 per 199 cy. This frequency is consistent with the radiological sampling requirement of 1 sample per 200 cy stipulated in the Work Plan.

3.4 Excavation Confirmation Sampling and Scanning

The limits of excavation for the burial pits were based on the visual identification of bedrock and/or native soils, as well as the absence of any buried debris or scrap. Initially chemical sampling was performed to verify that potential chemical of concern are at acceptable levels. Following receipt and review of chemical results, the excavations will undergo final radiological scanning and sampling consistent with a Class 1 survey unit.

Scanning will consist of measurements with a GPS-enabled Ludlum 44-20 3"x3" NaI with a data logger. The data will be statistically evaluated for outliers and will be plotted to identify spatial trends. Using the methodology described in Section 3.3, the appropriate number of systematic samples within the pits was calculated to be 10 per 2000 m^2 Class 1 survey unit, or 1.1 per 2500 square feet (ft^2). This frequency can be met by utilizing the sampling points from the chemical sampling activity (collected at a frequency of 1 sample per 2500 ft^2) and including an additional biased sample for every 10 systematic samples.

Each sample location will be logged by GPS, and will be subject to both a pre- and post-sampling one-minute scaler count with the 44-20.

NOTES:

	0.6	pCi/g Ra-226 (Bi-214)
Soil Bkg.	1.0	pCi/g Th-232 (Ac-228)

Sample IDs are as follows: **S12EXAA-B-B-CC**
The first three characters note the Area of Concern (i.e., SEAD-12).
EX designates that the sample is from an excavation.
AA Designates where in the excavation the sample was collected (FL=floor, SW=sidewall, PR=perimeter of top)
B-B designates the grid where the sample was collected
CC designates the sample number, assigned sequentially
If AA = STOCK, then sample was collected from overburden soils. These soils were used to backfill the pits, and thus, these results are reported along with pit surface results to represent current conditions in the pits.
Highlighted sample IDs are biased samples collected based on elevated gamma walkover survey results.

Results were derived as follows:

$$\frac{WMA}{\left(1-e^{-\lambda t}\right)} = \frac{WMA}{\left(1-e^{(-0.693\ /\ 3.8235^{*}\ 24)\ ^{*}(X\ +1.9117\ ^{*}24}\right)}$$

WMA = The weighted mean activity of ^{214}Bi and ^{214}Pb results, or $\left(\frac{\frac{^{214}Bi}{^{214}Bi_{CSV}} + \frac{^{214}Pb}{^{214}Pb_{CSV}}}{\frac{1}{^{214}Bi_{CSV}} + \frac{1}{^{214}Pb_{CSV}}} \right)$

where CSV is the combined standard variance of the result, calculated as follows: $\left(\frac{^{214}Bi_{TPU\ 95\%UL}}{1.96} \right)^2$

λ = -0.693 divided by 3.8235*24 (the half-life of ^{222}Rn in hours);
t = X (the elapsed in-growth time between the drying and sealing of the sample and the analysis of the sample in hours) plus 1.9117*24 (represents an assumption of 25% equilibrium of ^{222}Rn daughter products at the time of sealing).

Footnote

ND = Non-detect; DT = Detect; FOD = Frequency of Detection; Max = Maximum; Min = Minimum; Dist = Distribution; UCL_{95} - 95% upper confidence limit of the mean; EPC = Exposure Point Concentration

[a] Criteria - Frequency of Detection is greater than 5%

[b] The background concentration for Ra-228 was calculated based on the background dataset sampling results from the SEAD-12 RI (Parsons, 2002)

[c] Criteria - The maximum detected concentration is greater than the background concetration

[d] Dist = N = Normal; L= Lognormal; G = Gamma; X = Non-Parametric

[e] EPC = Minimum of (UCL95, Maximum Detected Concentration) - Background Concentration

[f] Evaluated as a part of its parent.

[g] The EPC for Pb-210 was set equal to its parent, Ra-226.

Footnote

ND = Non-detect; DT = Detect; FOD = Frequency of Detection; Max = Maximum; Min = Minimum; Dist = Distribution; UCL_{95} - 95% upper confidence limit of the mean; EPC = Exposure Point Concentration

[a] Criteria - Frequency of Detection is greater than 5%

[b] The background concentration for Ra-228 was calculated based on the background dataset sampling results from the SEAD-12 RI (Parsons, 2002)

[c] Criteria - The maximum detected concentration is greater than the background concetration

[d] Dist = N = Normal; L= Lognormal; G = Gamma; X = Non-Parametric

[e] EPC = Minimum of (UCL95, Maximum Detected Concentration) - Background Concentration

[f] Evaluated as a part of its parent.

[g] The EPC for Pb-210 was set equal to its parent, Ra-226.

[h] The background for Th-228 was set equal to Ra-228.

TABLE D-5: IDENTIFICATION OF GROUNDWATER ROPCS AND DETERMINATION OF EXPOSURE POINT CONCENTRATION OF EACH ROPC

DEFAULT AND RECOMMENDED VALUES FOR RESRAD INPUT PARAMETERS

RESRAD Version 6.5					Parameter Justification	
Parameter	**Code**	**Default Value**	**User Input Value**	**Units**	**Comments**	**Reference**
PATHWAY SELECTIONS						
External Gamma	N/A	Active	Active	N/A	RESRAD default used.	Parsons Engineering Science 2002
Inhalation (without radon)	N/A	Active	Active	N/A	RESRAD default used.	Parsons Engineering Science 2002
Plant Ingestion	N/A	Active	Inactive	N/A	Only active for Residential Farmer scenario	Parsons Engineering Science 2002
Meat Ingestion	N/A	Active	Inactive	N/A	Only active for Residential Farmer scenario	Parsons Engineering Science 2002
Milk Ingestion	N/A	Active	Inactive	N/A	Only active for Residential Farmer scenario	Parsons Engineering Science 2002
Aquatic Foods	N/A	Active	Inactive	N/A	Only active for Residential Farmer scenario	Parsons Engineering Science 2002
Drinking Water	N/A	Active	Inactive	N/A	Active for Future Park Worker, Recreation Receptor and Residential Farmer Scenario	Parsons Engineering Science 2002
Soil Ingestion	N/A	Active	Active	N/A	RESRAD default used.	Parsons Engineering Science 2002
Radon	N/A	Inactive	Inactive	N/A	Not applicable per cited reference.	NRC, 1994
CONTAMINATED ZONE PARAMETERS						
Area of contaminated zone	AREA	10,000	**2160** (Pit A/B) **8403** (Pit C)	m^2	Site-specific values were used.	Cabrera 2011
Thickness of contaminated zone	THICK0	2	**0.15** (Pit A/B) **0.15** (Pit C)	m	Site-specific average depth of contamination	Cabrera 2011
Length parallel to the aquifer	LCZPAQ	100	46.5 (Pit A/B) 92 (Pit C)	m	Square root of the area of contamination.	Calculated
Times for calculations	TI	1, 3, 10, 30, 100, 300, 1000	1, 3, 10, 30, 100, 300, 1000	yr	RESRAD defaults for calculation times.	ANL 1993
COVER AND CONTAMINATED ZONE HYDROLOGICAL DATA						
Cover depth	COVER	0	0	M	As a conservative approach, no cover depth was assumed.	ANL 1993 (Section 31)
Density of cover material	DENSCV	1.5	**N/A**	g/cm^3	Lack of cover depth precludes an assigned value for this parameter.	ANL 1993 (Section 2)
Cover erosion rate	VCV	0.001	**N/A**	m/yr	Lack of cover depth precludes an assigned value for this parameter.	ANL 1993 (Section 14)

DEFAULT AND RECOMMENDED VALUES FOR RESRAD INPUT PARAMETERS

RESRAD Version 6.5					Parameter Justification	
Parameter	**Code**	**Default Value**	**User Input Value**	**Units**	**Comments**	**Reference**
Density of contaminated zone	DENSCZ	1.5	**1.28**	g/cm^3	Site-specific value was chosen based on the average of silt loam and clay loam soil. (Table 2.1)	ANL 1993 (Section 2)
Contaminated zone erosion rate	VCZ	0.001	**0.0006** **0.00006**	m/yr	Resident (Assume 2% slope) All others	ANL 1993
Contaminated zone total porosity	TPCZ	0.4	**0.37**	Unitless	Site-specific value	ANL 1993 (Section 3) USAEHA 1984
Contaminated zone field capacity	FCCZ	0.2	**0.06**	Unitless	Site-specific value	Parsons Engineering Science 1996
Contaminated zone hydraulic conductivity	HCCZ	10	**29**	m/yr	Assumed to be a factor of 10 less than the site-specific saturated zone hydraulic conductivity of 290 m/yr of the *SEAD-12 RI Report* reference.	ANL 1993 (Section 5) Parsons Engineering Science 2002
Contaminated zone b parameter	BCZ	5.3	**7.75**	Unitless	The contaminated zone b parameter was selected from Table 13.1 of the reference for the silty clay loam.	ANL 1993 (Section 13)
Humidity in air	HUMID	8	**6.6**	g/m^3	Site-specific value	Parsons Engineering Science 2002
Evapotranspiration coefficient	EVAPTR	0.5	**0.7**	Unitless	See calculation in footnote (1) below	Parsons Engineering Science 1996
Wind speed	WIND	2	**3**	m/sec	Estimated using wind rose for Syracuse, NY	Parsons Engineering Science 2002
Precipitation	PRECIP	1	**0.75**	m/yr	Site-specific value based on reported 36.1 inches per year	ANL 1993 (Section 9), Parsons Engineering Science 2002
Irrigation	RI	0.2	**0**	m/yr	No irrigation onsite.	Parsons Engineering Science 2002
Irrigation mode	IDITCH	Overhead	Overhead	Unitless	The "Overhead" and "Ditch" designations are independent of the depth of contaminated zone and have no significant impact on the RESRAD evaluation. The RESRAD default designation was selected.	ANL 1993
Runoff coefficient	RUNOFF	0.2	0.2	Unitless	The RESRAD default value was selected based on reference value for intermediate combinations of clay and loam.	ANL 1993 (Section 10)

DEFAULT AND RECOMMENDED VALUES FOR RESRAD INPUT PARAMETERS

RESRAD Version 6.5					Parameter Justification	
Parameter	**Code**	**Default Value**	**User Input Value**	**Units**	**Comments**	**Reference**
Watershed area for nearby stream or pond	WAREA	1.00E6	**13000000**	m^2	Site-specific value (Appendix E, Table 2 of the reference)	ANL 1993 (Section 17), Parsons Engineering Science 2002
Accuracy for water/soil computations	EPS	0.001	0.001	Unitless	RESRAD default used.	ANL 1993
SATURATED ZONE HYDROLOGICAL DATA						
Density of saturated zone	DENSAQ	1.5	1.5	g/cm^3	RESRAD default used.	ANL 1993 (Section 2)
Saturated zone total porosity	TPSZ	0.4	**0.37**	Unitless	Site specific value	ANL 1993 (Section 3) USAEHA 1984
Saturated zone effective porosity	EPSZ	0.2	**0.175**	Unitless	Calculated value	Parsons Engineering Science 1996
Saturated zone field capacity	FCSZ	0.2	0.2	Unitless	RESRAD default used.	ANL 1993
Saturated zone hydraulic conductivity	HCSZ	100	**290**	m/yr	Saturated zone hydraulic conductivity for clay was based on a geometric mean hydraulic conductivity of 9.22×10^{-4} identified on Page 3-19 of the reference.	Parsons Engineering Science 2002
Saturated zone hydraulic gradient	HGWT	0.02	**0.011**	Unitless	Based on the average of the northern and southern values reported on page 3-19 of the reference.	Parsons Engineering Science 2002
Saturated zone b parameter	BSZ	5.3	5.3	Unitless	RESRAD default used.	ANL 1993 (Section 13)
Water table drop rate	VWT	0.001	**0**	m/yr	Assumption	ANL 1993 (Section 18)
Well pump intake depth (meters below water table)	DWIBWT	10	**3**	M	Site specific value	Parsons Engineering Science 2002
Model for Water Transport Parameters [Non-dispersion (ND) or Mass-Balance (MB)]	MODEL	ND	ND	unitless	RESRAD default used.	ANL 1993

DEFAULT AND RECOMMENDED VALUES FOR RESRAD INPUT PARAMETERS

RESRAD Version 6.5					Parameter Justification	
Parameter	**Code**	**Default Value**	**User Input Value**	**Units**	**Comments**	**Reference**
Well pumping rate	UW	250	**50**	m^3/yr	Based on field experience, 100 ml/min is a sustainable rate for extraction of groundwater from upper aquifer during well purging in preparation for groundwater sampling (as reported in Appendix E, Table 1 of the reference)	Parsons Engineering Science 2002
UNCONTAMINATED UNSATURATED ZONE PARAMETERS						
Number of unsaturated zone strata	NS	1	1	unitless	RESRAD default used.	ANL 1993 (Section 25)
Unsaturated zone thickness	H(1)	4	**1**	m	Site-specific measurement.	
Unsaturated zone soil density	DENSUZ(1)	1.5	1.5	g/cm^3	RESRAD default used.	ANL 1993 (Section 2)
Unsaturated zone total porosity	TPUZ(1)	0.4	**0.37**	unitless	Site specific value	ANL 1993 (Section 3), USAEHA 1984
Unsaturated zone effective porosity	EPSZ(1)	0.2	**0.175**	unitless	Calculated value	Parsons Engineering Science 1996
Unsaturated zone field capacity	FCSZ(1)	0.2	0.2	unitless	RESRAD default used.	ANL 1993
Unsaturated zone hydraulic conductivity	HCSZ(1)	10	**29**	m/yr	Assumed to be a factor of 10 less than the site-specific saturated zone hydraulic conductivity of 290 m/yr of the reference.	Parsons Engineering Science 2002
Unsaturated zone b parameter	BSZ	5.3	**7.75**	unitless	The assigned value was taken from Page 3-41 of the reference.	Parsons Engineering Science 2002
ELEMENTAL DISTRIBUTION (PARTITION) COEFFICIENTS AND LEACH RATES: ACTINIUM						
Contaminated zone	DCNUCC(2 & 3)	20	2,400	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
Unsaturated zone	DCNUCU(2 & 3,1)	20	2,400	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
Saturated zone	DCNUCS(2 & 3)	20	2,400	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
ELEMENTAL DISTRIBUTION (PARTITION) COEFFICIENTS AND LEACH RATES: COBALT						
Contaminated zone	DCNUCC(1)	1,000	**550**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993

DEFAULT AND RECOMMENDED VALUES FOR RESRAD INPUT PARAMETERS

RESRAD Version 6.5					Parameter Justification	
Parameter	**Code**	**Default Value**	**User Input Value**	**Units**	**Comments**	**Reference**
Unsaturated zone	DCNUCU(1,1)	1,000	**550**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
Saturated zone	DCNUCS(1)	1,000	**550**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
ELEMENTAL DISTRIBUTION (PARTITION) COEFFICIENTS AND LEACH RATES: CESIUM						
Contaminated zone	DCNUCC(1)	1,900	**1,900**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
Unsaturated zone	DCNUCU(1,1)	1,900	**1,900**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
Saturated zone	DCNUCS(1)	1,900	**1,900**	cm^3/g	This assigned value was selected from Table 32.1 of the reference for the clay.	ANL 1993
ELEMENTAL DISTRIBUTION (PARTITION) COEFFICIENTS AND LEACH RATES: RADIUM

Footnotes

N/A Not Applicable

(1) **Calculation of Evapotranspiration Coefficient**, RESRAD Manual, Version 5, page 198, with following parameters from Parsons Engineering Science, Final Groundwater Modeling Report at the Ash Landfill Site, June 1996.
I = Infiltration Rate, m/yr (7 in/year = 0.18 m/yr)
Ce = Evapotranspiration Coefficient
Cr = runoff coefficient (0.2)
Pr = Precipitation rate, annual rainfall, m/yr (0.75 m/yr)
Irr = Irrigation rate (0 m/yr)

(2) Determination of Inhalation Rate for the Residential Receptors

Inhalation Rate for Child (0-1)

Age Group	Month	Mean Inhalation Rate (m^3/day)	References
0-1	1	3.6	**Mean value from Table 6-1 of EFH (USEPA, 2011)**
1-3	2	3.5	
4-6	3	4.1	
7-12	6	5.4	
Weighted Inhalation Rate for Child (0-1)		**4.61**	

Inhalation Rate for Child (0-6)

					Weighted Intake Rate		**257.10**	

Consumption Rate for Adult

Age Group	Years	Fruit Intake (g/kg-day)	Vegetable Intake (g/kg-day)	Grain Intake (g/kg-day)	Total Intake Rate (g/kg-day)	Body Weight (kg)	Intake Rate (g/day)	References
18-21	3	0.9	2.3	2.4	5.6	71.6	401.0	Mean Value from Table ES-1 of EFH (USEPA, 2011)
21-42	21	0.9	2.5	2.2	5.6	80	448.0	
					Weighted Intake Rate		**442.12**	

Age-Weighted Total Fruits, Vegetables and Grains Consumption Rate

Receptor	Intake Rate (g/day)	Intake Rate (kg/yr)	Exposure Duration (yr)	Weighted Consumption Rate (kg/yr)
Child	257.10	93.84	6	**147.9**
Adult	442.12	161.37	24	

Footnote

[1] Age-weighted total consumption rate = (93.84*6 + 161.37*24)/(24+6)

(4) Determination of Total Leafy Vegetables Consumption Rate for Residential Receptor

Based on USDA report, *Food Consumption, Prices and Expenditures 1970-1997* (Putnam et al., 1999), fresh vegetables accounted for 44% of the total vegetables consumed during the 25-year period. The fraction of non-leafy fresh vegetables consumed from 1972 – 1997 was estimated at 0.67 of the total fresh vegetable consumption rate.

The above statistics were considered during the estimation of leafy vegetable consumption rate for residential receptor.

Body Weight for Child (0-1)

Age Group	Month	Mean Weight (Kg)	References
0-1	1	4.8	**Mean value from Table ES-1 of EFH (USEPA, 2011)**
1-3	2	5.9	
3-6	3	7.4	
6-12	6	9.2	
Weighted Body Weight for Child (0-1)		**7.83**	

Consumption Rate for Child (0-6)

Toxicological Properties of ROPCs

This page intentionally left blank

Table F-1: Dose Conversation Factor for ROPCs

ROPC[a]	Dose Conversation Factors (mrem/pCi)		
	Ingestion[b]	Inhalation[b]	External Exposure[c]
Actinium-227+D [d]	1.48E-02	6.72E+00	2.01
Cesium-137+D [d]	5.00E-05	3.19E-05	3.41
Tritium	6.40E-08	6.40E-08	0
Lead-210+D [d]	7.28E-03	2.32E-02	6.05E-03
Promethium-147	1.05E-06	5.01E-05	3.92E-05
Radium-226+D [d]	1.32E-03	8.59E-03	1.12E+01
Radium-228+D [d]	1.44E-03	5.08E-03	5.98E+00
Thorium-230	5.48E-04	3.26E-01	1.21E-03

Footnotes

[a] ROPC = Radionuclides of Potential Concern.

[b] USEPA 1988. Federal Guidance Report No. 11, Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion and Ingestion. EPA 520/1-88-020, Air and Radiation, September.

[c] USEPA 1993. Federal Guidance Report No. 12, External Exposure to Radionuclides in Air, Water; and Soil, EPA 402-R-93-081, Air and Radiation, September.

[d] +D slope factors include contributions from short-lived daughter products.

Table F-2: Risk Coefficient Values for ROPCs

ROPC[a]	Cancer Slope Factors[b] (Risk/pCi)						
	Water Ingestion	Food Ingestion	Soil Ingestion	Inhalation	External Exposure[c]	EPA Class	ICRP Lung Class[d]
Actinium-227+D [e]	4.86E-10	6.53E-10	6.53E-10	2.13E-07	1.47E-06	A	S
Cesium-137+D [e]	3.04E-11	3.74E-11	3.74E-11	1.12E-10	2.55E-06	A	F
Tritium	1.12E-13	1.44E-13	1.44E-13	8.51E-13	0.00E+00	A	V
Lead-210+D [e]	2.66E-09	3.44E-09	2.66E-09	3.08E-08	4.21E-09	A	M
Promethium-147	1.69E-12	2.48E-12	4.88E-12	1.61E-11	3.21E-11	A	S
Radium-226+D [e]	3.86E-10	5.15E-10	7.30E-10	2.83E-08	8.49E-06	A	M
Radium-228+D [e]	1.04E-09	1.43E-09	2.29E-09	4.37E-08	4.53E-06	A	M
Thorium-230	9.10E-11	1.19E-10	2.02E-10	3.40E-08	8.19E-10	A	S

Footnotes

#For DCF1(xxx) only factors are for infinite depth & area. See ETFG table in Ground Pathway of Detailed Report.
*Base Case means Default.Lib w/o Associate Nuclide contributions.

Site-Specific Parameter Summary

Menu	Parameter	User Input	Default	Used by RESRAD (If different from user input)	Parameter Name
R011	Area of contaminated zone (m**2)	2.160E+03	1.000E+04	---	AREA
R011	Thickness of contaminated zone (m)	1.500E-01	2.000E+00	---	THICK0
R011	Fraction of contamination that is submerged	0.000E+00	0.000E+00	---	SUBMFRACT
R011	Length parallel to aquifer flow (m)	4.650E+01	1.000E+02	---	LCZPAQ
R011	Basic radiation dose limit (mrem/yr)	2.500E+01	3.000E+01	---	BRDL
R011	Time since placement of material (yr)	0.000E+00	0.000E+00	---	TI
R011	Times for calculations (yr)	1.000E+00	1.000E+00	---	T(2)
R011	Times for calculations (yr)	2.000E+00	3.000E+00	---	T(3)
R011	Times for calculations (yr)	3.000E+00	1.000E+01	---	T(4)
R011	Times for calculations (yr)	1.000E+01	3.000E+01	---	T(5)
R011	Times for calculations (yr)	3.000E+01	1.000E+02	---	T(6)
R011	Times for calculations (yr)	1.000E+02	3.000E+02	---	T(7)
R011	Times for calculations (yr)	3.000E+02	1.000E+03	---	T(8)
R011	Times for calculations (yr)	1.000E+03	0.000E+00	---	T(9)
R011	Times for calculations (yr)	not used	0.000E+00	---	T(10)
R012	Initial principal radionuclide (pCi/g): Cs-137	1.000E+00	0.000E+00	---	S1(1)
R012	Initial principal radionuclide (pCi/g): H-3	1.000E+00	0.000E+00	---	S1(2)
R012	Initial principal radionuclide (pCi/g): Th-230	1.000E+00	0.000E+00	---	S1(5)
R012	Concentration in groundwater (pCi/L): Cs-137	not used	0.000E+00	---	W1(1)
R012	Concentration in groundwater (pCi/L): H-3	not used	0.000E+00	---	W1(2)
R012	Concentration in groundwater (pCi/L): Th-230	not used	0.000E+00	---	W1(5)
R013	Cover depth (m)	0.000E+00	0.000E+00	---	COVER0
R013	Density of cover material (g/cm**3)	not used	1.500E+00	---	DENSCV
R013	Cover depth erosion rate (m/yr)	not used	1.000E-03	---	VCV
R013	Density of contaminated zone (g/cm**3)	1.280E+00	1.500E+00	---	DENSCZ
R013	Contaminated zone erosion rate (m/yr)	6.000E-05	1.000E-03	---	VCZ
R013	Contaminated zone total porosity	3.700E-01	4.000E-01	---	TPCZ
R013	Contaminated zone field capacity	6.000E-02	2.000E-01	---	FCCZ
R013	Contaminated zone hydraulic conductivity (m/yr)	2.900E+01	1.000E+01	---	HCCZ
R013	Contaminated zone b parameter	7.750E+00	5.300E+00	---	BCZ
R013	Average annual wind speed (m/sec)	3.000E+00	2.000E+00	---	WIND
R013	Humidity in air (g/m**3)	6.600E+00	8.000E+00	---	HUMID
R013	Evapotranspiration coefficient	7.000E-01	5.000E-01	---	EVAPTR
R013	Precipitation (m/yr)	7.500E-01	1.000E+00	---	PRECIP
R013	Irrigation (m/yr)	0.000E+00	2.000E-01	---	RI
R013	Irrigation mode	overhead	overhead	---	IDITCH
R013	Runoff coefficient	2.000E-01	2.000E-01	---	RUNOFF
R013	Watershed area for nearby stream or pond (m**2)	1.300E+07	1.000E+06	---	WAREA
R013	Accuracy for water/soil computations	1.000E-03	1.000E-03	---	EPS

R014	Density of saturated zone (g/cm**3)	1.500E+00	1.500E+00	---	DENSAQ
R014	Saturated zone total porosity	3.700E-01	4.000E-01	---	TPSZ
R014	Saturated zone effective porosity	1.750E-01	2.000E-01	---	EPSZ
R014	Saturated zone field capacity	2.000E-01	2.000E-01	---	FCSZ
R014	Saturated zone hydraulic conductivity (m/yr)	2.900E+02	1.000E+02	---	HCSZ
R014	Saturated zone hydraulic gradient	1.100E-02	2.000E-02	---	HGWT
R014	Saturated zone b parameter	not used	5.300E+00	---	BSZ
R014	Water table drop rate (m/yr)	0.000E+00	1.000E-03	---	VWT

Site-Specific Parameter Summary (continued)

Summary of Pathway Selections

Pathway	User Selection
1 -- external gamma	active
2 -- inhalation (w/o radon)	active
3 -- plant ingestion	suppressed
4 -- meat ingestion	suppressed
5 -- milk ingestion	suppressed
6 -- aquatic foods	suppressed
7 -- drinking water	active
8 -- soil ingestion	active
9 -- radon	suppressed
Find peak pathway doses	suppressed

Site-Specific Parameter Summary (continued)

Menu	Parameter	User Input	Default	Used by RESRAD (If different from user input)	Parameter Name
STOR	Storage times of contaminated foodstuffs (days):				
STOR	Fruits non-leafy vegetables and grain	1.400E+01	1.400E+01	---	STOR_T(1)
STOR	Leafy vegetables	1.000E+00	1.000E+00	---	STOR_T(2)
STOR	Milk	1.000E+00	1.000E+00	---	STOR_T(3)
STOR	Meat and poultry	2.000E+01	2.000E+01	---	STOR_T(4)
STOR	Fish	7.000E+00	7.000E+00	---	STOR_T(5)
STOR	Crustacea and mollusks	7.000E+00	7.000E+00	---	STOR_T(6)
STOR	Well water	1.000E+00	1.000E+00	---	STOR_T(7)
STOR	Surface water	1.000E+00	1.000E+00	---	STOR_T(8)
STOR	Livestock fodder	4.500E+01	4.500E+01	---	STOR_T(9)
R021	Thickness of building foundation (m)	not used	1.500E-01	---	FLOOR1
R021	Bulk density of building foundation (g/cm**3)	not used	2.400E+00	---	DENSFL
R021	Total porosity of the cover material	not used	4.000E-01	---	TPCV
R021	Total porosity of the building foundation	not used	1.000E-01	---	TPFL
R021	Volumetric water content of the cover material	not used	5.000E-02	---	PH2OCV
R021	Volumetric water content of the foundation	not used	3.000E-02	---	PH2OFL
R021	Diffusion coefficient for radon gas (m/sec):				
R021	in cover material	not used	2.000E-06	---	DIFCV
R021	in foundation material	not used	3.000E-07	---	DIFFL
R021	in contaminated zone soil	not used	2.000E-06	---	DIFCZ
R021	Radon vertical dimension of mixing (m)	not used	2.000E+00	---	HMIX
R021	Average building air exchange rate (1/hr)	not used	5.000E-01	---	REXG
R021	Height of the building (room) (m)	not used	2.500E+00	---	HRM
R021	Building interior area factor	not used	0.000E+00	---	FAI
R021	Building depth below ground surface (m)	not used	-1.000E+00	---	DMFL
R021	Emanating power of Rn-222 gas	not used	2.500E-01	---	EMANA(1)
R021	Emanating power of Rn-220 gas	not used	1.500E-01	---	EMANA(2)
TITL	Number of graphical time points	32	---	---	NPTS
TITL	Maximum number of integration points for dose	17	---	---	LYMAX
TITL	Maximum number of integration points for risk	1	---	---	KYMAX

Summary of Pathway Selections

Pathway	User Selection
1 -- external gamma	active
2 -- inhalation (w/o radon)	active
3 -- plant ingestion	suppressed
4 -- meat ingestion	suppressed
5 -- milk ingestion	suppressed
6 -- aquatic foods	suppressed
7 -- drinking water	active
8 -- soil ingestion	active
9 -- radon	suppressed
Find peak pathway doses	suppressed

#For DCF1(xxx) only factors are for infinite depth & area. See ETFG table in Ground Pathway of Detailed Report.
*Base Case means Default.Lib w/o Associate Nuclide contributions.

Site-Specific Parameter Summary

Menu	Parameter	User Input	Default	Used by RESRAD (If different from user input)	Parameter Name
R011	Area of contaminated zone (m**2)	2.160E+03	1.000E+04	---	AREA
R011	Thickness of contaminated zone (m)	1.500E-01	2.000E+00	---	THICK0
R011	Fraction of contamination that is submerged	0.000E+00	0.000E+00	---	SUBMFRACT
R011	Length parallel to aquifer flow (m)	4.650E+01	1.000E+02	---	LCZPAQ
R011	Basic radiation dose limit (mrem/yr)	2.500E+01	3.000E+01	---	BRDL
R011	Time since placement of material (yr)	0.000E+00	0.000E+00	---	TI
R011	Times for calculations (yr)	1.000E+00	1.000E+00	---	T(2)
R011	Times for calculations (yr)	2.000E+00	3.000E+00	---	T(3)
R011	Times for calculations (yr)	3.000E+00	1.000E+01	---	T(4)
R011	Times for calculations (yr)	1.000E+01	3.000E+01	---	T(5)
R011	Times for calculations (yr)	3.000E+01	1.000E+02	---	T(6)
R011	Times for calculations (yr)	1.000E+02	3.000E+02	---	T(7)
R011	Times for calculations (yr)	3.000E+02	1.000E+03	---	T(8)
R011	Times for calculations (yr)	1.000E+03	0.000E+00	---	T(9)
R011	Times for calculations (yr)	not used	0.000E+00	---	T(10)
R012	Initial principal radionuclide (pCi/g): Ac-227	1.000E+00	0.000E+00	---	S1(1)
R012	Initial principal radionuclide (pCi/g): Cs-137	1.000E+00	0.000E+00	---	S1(2)
R012	Initial principal radionuclide (pCi/g): H-3	1.000E+00	0.000E+00	---	S1(3)
R012	Initial principal radionuclide (pCi/g): Th-230	1.000E+00	0.000E+00	---	S1(6)
R012	Concentration in groundwater (pCi/L): Ac-227	not used	0.000E+00	---	W1(1)
R012	Concentration in groundwater (pCi/L): Cs-137	not used	0.000E+00	---	W1(2)
R012	Concentration in groundwater (pCi/L): H-3	not used	0.000E+00	---	W1(3)
R012	Concentration in groundwater (pCi/L): Th-230	not used	0.000E+00	---	W1(6)
R013	Cover depth (m)	0.000E+00	0.000E+00	---	COVER0
R013	Density of cover material (g/cm**3)	not used	1.500E+00	---	DENSCV
R013	Cover depth erosion rate (m/yr)	not used	1.000E-03	---	VCV
R013	Density of contaminated zone (g/cm**3)	1.280E+00	1.500E+00	---	DENSCZ
R013	Contaminated zone erosion rate (m/yr)	6.000E-04	1.000E-03	---	VCZ
R013	Contaminated zone total porosity	3.700E-01	4.000E-01	---	TPCZ
R013	Contaminated zone field capacity	6.000E-02	2.000E-01	---	FCCZ
R013	Contaminated zone hydraulic conductivity (m/yr)	2.900E+01	1.000E+01	---	HCCZ
R013	Contaminated zone b parameter	7.750E+00	5.300E+00	---	BCZ
R013	Average annual wind speed (m/sec)	3.000E+00	2.000E+00	---	WIND
R013	Humidity in air (g/m**3)	6.600E+00	8.000E+00	---	HUMID
R013	Evapotranspiration coefficient	7.000E-01	5.000E-01	---	EVAPTR
R013	Precipitation (m/yr)	7.500E-01	1.000E+00	---	PRECIP
R013	Irrigation (m/yr)	0.000E+00	2.000E-01	---	RI
R013	Irrigation mode	overhead	overhead	---	IDITCH
R013	Runoff coefficient	2.000E-01	2.000E-01	---	RUNOFF
R013	Watershed area for nearby stream or pond (m**2)	1.300E+07	1.000E+06	---	WAREA

R013	Accuracy for water/soil computations	1.000E-03	1.000E-03	---	EPS
R014	Density of saturated zone (g/cm**3)	1.500E+00	1.500E+00	---	DENSAQ
R014	Saturated zone total porosity	3.700E-01	4.000E-01	---	TPSZ
R014	Saturated zone effective porosity	1.750E-01	2.000E-01	---	EPSZ
R014	Saturated zone field capacity	2.000E-01	2.000E-01	---	FCSZ
R014	Saturated zone hydraulic conductivity (m/yr)	2.900E+02	1.000E+02	---	HCSZ
R014	Saturated zone hydraulic gradient	1.100E-02	2.000E-02	---	HGWT

Site-Specific Parameter Summary (continued)

Menu	Parameter	User Input	Default	Used by RESRAD (If different from user input)	Parameter Name
R014	Saturated zone b parameter	not used	5.300E+00	---	BSZ
R014	Water table drop rate (m/yr)	0.000E+00	1.000E-03	---	VWT
R014	Well pump intake depth (m below water table)	3.000E+00	1.000E+01	---	DWIBWT
R014	Model: Nondispersion (ND) or Mass-Balance (MB)	ND	ND	---	MODEL
R014	Well pumping rate (m**3/yr)	5.000E+01	2.500E+02	---	UW
R015	Number of unsaturated zone strata	1	1	---	NS

R021	Thickness of building foundation (m)	not used	1.500E-01	---	FLOOR1
R021	Bulk density of building foundation (g/cm**3)	not used	2.400E+00	---	DENSFL
R021	Total porosity of the cover material	not used	4.000E-01	---	TPCV
R021	Total porosity of the building foundation	not used	1.000E-01	---	TPFL
R021	Volumetric water content of the cover material	not used	5.000E-02	---	PH2OCV
R021	Volumetric water content of the foundation	not used	3.000E-02	---	PH2OFL
R021	Diffusion coefficient for radon gas (m/sec):				
R021	in cover material	not used	2.000E-06	---	DIFCV
R021	in foundation material	not used	3.000E-07	---	DIFFL
R021	in contaminated zone soil	not used	2.000E-06	---	DIFCZ
R021	Radon vertical dimension of mixing (m)	not used	2.000E+00	---	HMIX
R021	Average building air exchange rate (1/hr)	not used	5.000E-01	---	REXG
R021	Height of the building (room) (m)	not used	2.500E+00	---	HRM
R021	Building interior area factor	not used	0.000E+00	---	FAI
R021	Building depth below ground surface (m)	not used	-1.000E+00	---	DMFL
R021	Emanating power of Rn-222 gas	not used	2.500E-01	---	EMANA(1)
R021	Emanating power of Rn-220 gas	not used	1.500E-01	---	EMANA(2)
TITL	Number of graphical time points	32	---	---	NPTS
TITL	Maximum number of integration points for dose	17	---	---	LYMAX
TITL	Maximum number of integration points for risk	1	---	---	KYMAX

Summary of Pathway Selections

Pathway	User Selection
1 -- external gamma	active
2 -- inhalation (w/o radon)	active
3 -- plant ingestion	active
4 -- meat ingestion	active
5 -- milk ingestion	active
6 -- aquatic foods	active
7 -- drinking water	active
8 -- soil ingestion	active
9 -- radon	suppressed
Find peak pathway doses	suppressed

Summary : Residual Dose and Risk Assessment for SEAD 12 Under Residential Receptor Scenar
