1.0 PURPOSE AND INTRODUCTION

This action memorandum proposes a remedial program which will utilize thermal desorption of excavated soils impacted with chlorinated hydrocarbons at the Ash Landfill site at the Seneca Army Depot (SEDA) in Romulus, New York. The SEDA is a Federal Section National Priorities List (NPL) site. This document has been prepared by Engineering-Science, Inc. (ES) of Boston which has been retained by the United States Army Corps of Engineers (USACE). The work to be performed will be conducted in full compliance with the requirements of the Comprehensive Environmental Responsibility, Compensation, and Liability Act (CERCLA) to perform these activities.

The purpose of this action memorandum is to describe the process for the proposed non-time-critical removal action at the former Ash Landfill. This removal action is an interim remedial measure (IRM), and is not intended to be the final remedy for the entire Ash landfill site. The primary objective of the removal action is distinct, and is to eliminate or significantly reduce the potential for human or environmental exposure to contamination through uncontrolled releases of trichloroethene (TCE), vinylchloride (VC) and dichlroethene (DCE) to groundwater from contaminanted soils. An Engineering Evaluation/Cost Analysis (EE/CA) was conducted to evaluate the various remedial options for the site, and to select the best option. The EE/CA is included as Appendix A.

This work is based primarily upon the data collected during the Remedial Investigation (RI) for the Ash Landfill. Activities conducted as part of the RI included geophysical surveys, soil gas surveys, soil borings and test pits to gather stratigraphic information, soil samples for analytical testing, and construction and sampling of groundwater monitoring wells. The primary focus of this removal action is an area known as the "bend in the road" at the SEDA Ash Landfill. This area was identified during the RI as the primary source of volatile organic contamination at the site.

The removal action for the SEDA Ash Landfill is not financed by Superfund. Therefore, the requirements of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) in section 300.415(b)(5) for fund-financed removal actions do not apply.

It should be noted that SEDA is a RCRA treatment and storage facility, and that the remedial activities conducted at SEDA are equivalent to and will satisfy RCRA requirements for correction action. Specifically, this Removal Action satisfies the requirements of a RCRA Interim Corrective Measure.

2.0 SITE CONDITIONS AND BACKGROUND

The following discussion is based on information presented in previous reports prepared for the SEDA Ash Landfill.

2.1 SITE DESCRIPTION

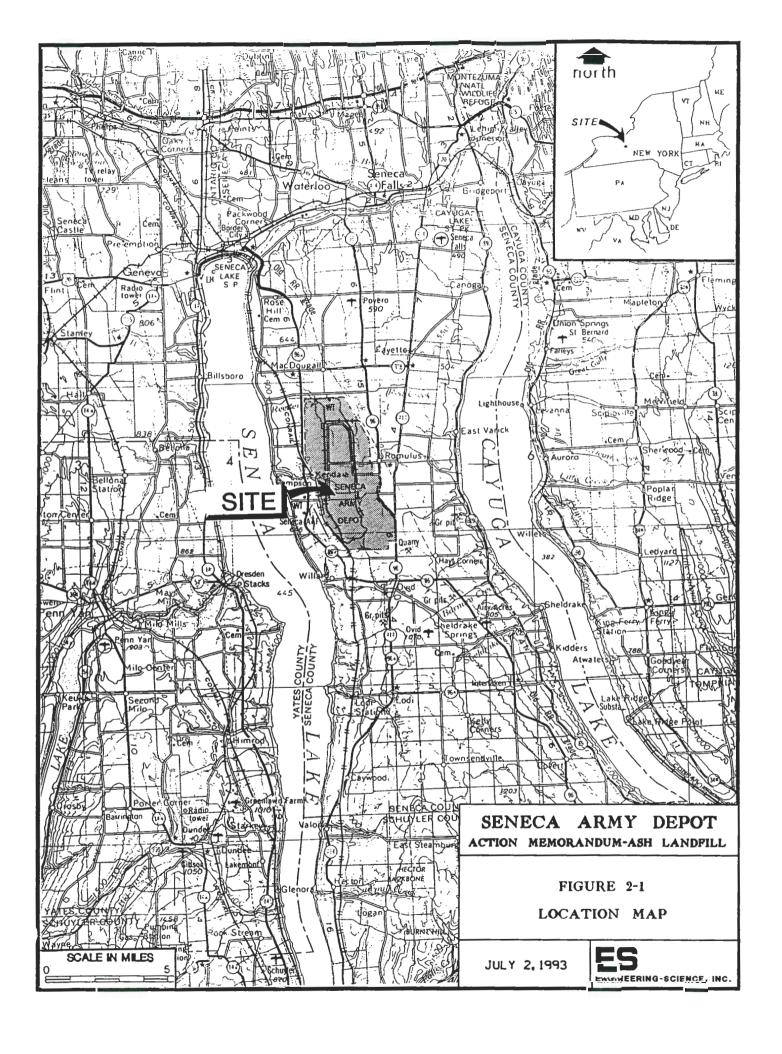

2.1.1 Base History

SEDA is located in Romulus, New York between Cayuga and Seneca lakes in the Finger Lakes region of central New York (Figure 2-1). SEDA was constructed in 1941 and has been owned by the United States Government and operated by the Department of the Army since this time. The post generally consists of an elongated central area for storage of ammunitions and weaponry in quonset-style buildings, an operations and administration area in the eastern portion and an army barracks area at the north end of the depot. Base housing for Army Personnel and their families is located in a 54-acre development adjacent to Route 96 and in another 69-acre development situated on Seneca Lake. The base was expanded to encompass a 1,524-meter airstrip, formerly the Sampson Air Force Base. The primary mission of SEDA is the management of munitions. Currently, SEDA is used for: 1) receiving, storing, and distributing ammunition and explosives, 2) providing receipt, storage, and distribution of military items; and 3) performing depot-level maintenance, demilitarization, and surveillance on conventional ammunition and special weapons. The depot currently employs less than 1,000 civilian and military personnel.

SEDA is being downsized, and will possibly be closed in the near future. The facility will continue to be operated by civilians whose primary responsibilities will include environmental restoration and demilitarization projects. No Army personnel or their dependents will be housed on the depot.

The depot lies immediately west of the village of Romulus (Figure 2-1), 12 miles south of the villages of Seneca Falls and Waterloo, and 2.5 miles north of the village of Ovid. The nearest major cities are Syracuse and Rochester, located 60 miles northeast and northwest, respectively. Land use in the area includes farms, dairy farms, suburban residential areas, and some light industrial areas.

May, 1994 Page 2-1

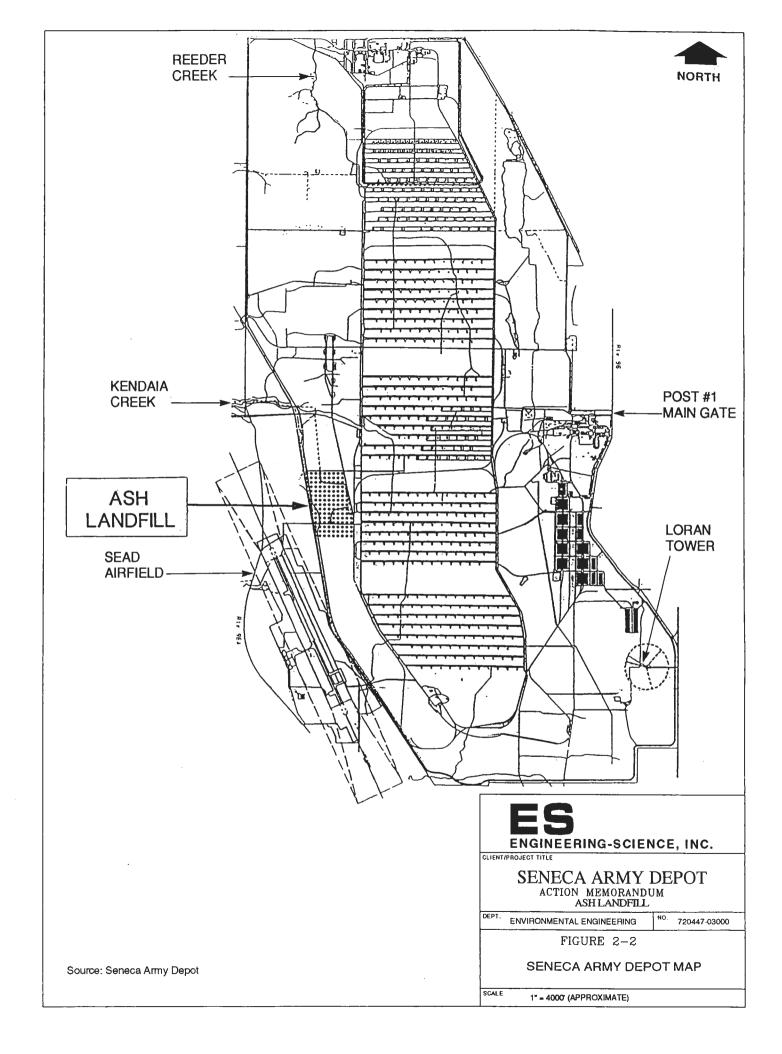

2.1.2 Site History

The Ash Landfill site encompasses approximately 130 acres about 2,000 feet east of the northwestern extension of the SEDA airstrip in the southwestern portion of the 10,587-acre SEDA. The site consists of an abandoned incinerator building and stack, a former cooling pond, an Ash Landfill, and a nearby Non-Combustible Fill Landfill (Figure 2-2). The site is bounded on the north by Cemetery Road, on the east by a SEDA railroad line, on the south by undeveloped SEDA land, and on the west by the depot's boundary. Beyond the depot's western boundary are farmland and residences on Smith Farm Road and along Route 96A, with Sampson State Park near Seneca Lake is further to the west. The nearest residence is located approximately 2,500 feet west of the landfill.

From 1941 to 1974, uncontaminated trash was burned in a series of burn pits east of the abandoned incinerator building. The ash from the refuse burning pits was buried in the landfill. The incinerator was built in 1974 and took the place of the open burning pits. Nearly all of the approximately 18 tons of refuse generated per week on the depot were incinerated. The source for the refuse was domestic waste from depot activities and family housing. Large items which could not be burned were disposed of at the non-combustible fill landfill.

Ashes and other residues from the incinerator were temporarily disposed of in an unlined cooling pond immediately north of the incinerator building. When the pond filled (approximately every 18 months), the fly ash and residues were removed, transported, and buried in the adjacent landfill east of the cooling pond. The refuse was dumped in piles and occasionally spread and compacted. The active area of the Ash Landfill extended at least 500 feet north at the incinerator building near a bend in a dirt road, as seen in an undated aerial photograph of the incinerator during operation. Parallel grooves at the northernmost extent of the filled area are visible in the aerial view of the incinerator and adjacent fill area during active operation and indicate that the fill was spread using a bulldozer or similar equipment. The incinerator was destroyed by a fire on May 8, 1979, and the landfill was subsequently closed. The landfill was capped with native soils of various thicknesses but has not been closed with an engineered cover or cap.

Page 2-3 May, 1994

2.1.3 Site Characteristics

2.1.3.1 Geology

The site is located in the Finger Lakes region of New York, which is underlain by a broad north-to-south trending series of rock terraces mantled by glacial till. As part of the Appalachian Plateau, the region is underlain by a tectonically undisturbed sequence of Paleozoic rocks consisting of shales, sandstones, conglomerates, limestones and dolostones. Locally, the shale is soft, grey, and fissile, and is mapped as the upper member of the Hamilton Group. The shale contains interbeds of calcareous shale and limestone.

Pleistocene age glacial till deposits overlie the shales. The till matrix, the result of glaciation, varies locally but generally consists of horizons of unsorted silt, clay, sand, and gravel. In the Finger Lakes region the till thickness varies from 1 to 50 meters. However, on the till plain between Seneca and Cayuga Lake it is near the surface and generally thin (Muller and Cadwell, 1986). The soils at the site are classified as unsorted inorganic clays, inorganic silts, and silty sands. Gray competent shale was encountered between 6 and 14 feet below the land surface in all borings on the site and in off-site surrounding areas. The topography slopes consistently to the west from an elevation of 720 feet in the eastern portion of the site to 614 feet in the western portion of the site. Bedrock topographic gradients are steepest in the eastern portion of the site (as is land surface topography) and in the southwestern portion of the site where they shift slightly to the southwest.

A thin (1.5 to 12 feet thick) zone of gray weathered shale was encountered in almost all locations drilled on-site. This zone is characterized by fissile shale with a large amount of brown interstitial silt and clay. No outcrops of weathered or competent shale are exposed on the site, however, several shale pits are located throughout the facility.

A 2 to 11 foot thick mantle of dense glacial till covers the shale on-site. The till is generally characterized by brown to gray-brown silt, clay and fine sand with few fine to coarse gravel-sized inclusions of weathered shale. Darian silt-loam soils, 0 to 18 inches thick, are developed over the till on-site, however, in some locations till is exposed at the surface. The surficial soils are somewhat poorly drained and have a silt clay loam and clay sub soil. In general, the topographic relief associated with these soils is 3 to 8%.

May, 1994 Page 2-5

2.1.3.2 Hydrogeology

The hydrogeologic properties of the site were characterized during the Phase I and Phase II remedial investigations. A full discussion can be found in the RI and the EE/CA (Appendix A).

The general direction of groundwater flow in the shallow aquifer is to the west toward Seneca Lake following surface topography. Shallow aguifer elevations are approximately 655 feet in the eastern portion of the site and drop to a low of 630 feet in the western portion of the site.

A flow direction for the deep competent shale aquifer can not be accurately determined from the array of wells on the site since flow is through fractures in bedrock. groundwater elevations in deep wells are higher in the eastern portion of the site (between approximately 680 and 686 feet) than they are in the western portion of the site (between approximately 630 and 634 feet) suggesting a westerly direction of flow in the deep aquifer is likely similar to the overburden aquifer.

2.1.3.3 Area Meteorology

Table 2-1 summarizes climatological data for the SEDA area. A cool climate exists with temperatures ranging from an average of 23°F in January to 69°F in July. Marked temperature differences are found between daytime highs and nighttime lows during the summer and portions of the transitional seasons. Precipitation is well-distributed, averaging approximately 3 inches per month. The annual average snowfall is approximately 100 inches. Wind velocities are moderate, but during the winter months, there are numerous days with sufficient winds to cause blowing and drifting snow. The most frequently occurring wind directions are westerly and west-southwesterly.

As Table 2-1 shows, temperatures tend to be highest from June through September. Precipitation and relative humidity tend to be rather high throughout the year. The months with the most amount of sunshine are June through September.

2.1.4 Contamination Assessment

The results of the RI are summarized below. These activities include both screening (such as soil gas surveys) and confirmation sampling. The primary purpose of the screening activities was to provide information to be used in locating the soil borings. Confirmation sampling was used to confirm the extent of the contamination and to positively identify the contaminants present.

2.1.4.1 Soil Gas

Three separate soil gas investigations have been carried out at the SEDA Ash Landfill. The first was conducted by Target Environmental, Inc. (Target) under the supervision of ICF Technology, Inc. and is included as part of the USATHAMA RI/FS submitted in March 1989. In their investigation, Target assembled a grid over the entire Ash Landfill site in order to identify potential hot spots. The highest concentration determined was from an area southeast of the bend-in-the-road which contained a concentration of 11,000 µg/L of total volatiles. The second highest soil gas value was 655 µg/L which was located at the bend in the road.

The next soil gas investigation was conducted in 1991 by MAIN. The concentration units for this investigation was parts-per-million by volume (ppmv) expressed as TCE equivalents. This investigation attempted to build upon the results of the Target investigation by further investigating the known areas of contamination and identify the presence of volatiles at geophysical anomalies previously determined. No elevated soil gas concentrations were determined at any geophysical anomalies. The results of MAIN's investigation correlated reasonably well with the two elevated soil gas results of the Target investigation, however, MAIN's data suggested that both the extent and magnitude of the concentration at the bendin-the-road area were greater than previously determined by Target. Near the bend in the road, total volatile organics in soil gas were as high as 86.6 ppmv at SG-70. A 1 ppmv total volatile organics isocontour encompasses an area approximately 250 feet by 175 feet (Figure 2-3). This area appeared to extend to the south toward the Ash Landfill and the incinerator building. TCE concentrations in soil gas are also provided on Figure 2-3. The soil gas survey clearly identified a source area for volatile organic compounds in soil (i.e., area encompassed by 1 ppmv isocontour). Experience from previous soil gas surveys suggest that concentration exceeding 1 ppmv are indicative of areas where the soil is considered contaminated.

Areas identified in the Target (1989) soil gas survey with soil gas concentrations of over 100 ug/l (17 ppmv as TCE) are identified on Figure 2-3. In the southeasternmost location, a total volatile organics concentration of approximately 11,000 μg/l (approximately 1,880 ppmv as TCE) was detected, the highest concentration detected in the Target (1989) survey. As a basis for comparison, this location was sampled during MAIN's soil gas survey (SG-14) and a concentration of approximately 50 ppmv was determined. Differences in concentration are not unexpected using soil gas techniques, and at this location this difference is not unexpected. However, soil gas concentrations determined by MAIN are higher near the bend in the unpaved road (up to 86.6 ppmv) than was previously identified by Target.

Page 2-8 May, 1994

As a Phase II follow-up to the MAIN soil gas survey, the next soil gas investigation was carried out by ES (formerly MAIN) in 1993. The purpose of this investigation was to fully delineate the two hot spots identified near the bend in the road. The original plan was to conduct the investigation using the same methodology as that of the MAIN investigation. However, due to heavy precipitation, the surface soils at the site were saturated, and the water table was extremely high. This eliminated the possibility of performing soil gas, since no soil gas is present, necessitating a change in the work plan. For this phase of the investigation, two 2-inch-diameter, 2 foot long split spoons were driven to a depth of 4 feet. The first spoon sample was discarded. A soil sample from approximately 10 grams, the second spoon at a depth of 2 to 4 feet was collected and placed in a 40-ml VOA vial with a Teflon septum. Headspace samples were collected from the vial and analyzed in a manner similar to the analysis of the soil gas using a Photovac Model 10S-50 portable GC.

The results of this investigation are summarized in Table 2-2 and Figure 2-3. Areas of contamination were fully delineated, and soil borings were collected both inside and outside the areas of contamination in order to confirm the results of the investigation. The soil headspace survey indicated two areas of contamination of approximately 38,000 and 17,000 square feet, which will be remediated as part of this removal action.

2.1.4.2 Soil

Volatile organic compounds were the primary contaminant of concern present in most of the soil samples collected during drilling. The volatile organics include TCE, 1,2-DCE (total), tetrachloroethene, 1,2-dichloroethane (one occurrence), 1,1,1-trichloroethane, chloroform, 2-butanone, benzene, toluene, ethylbenzene, xylene, methylene chloride and acetone. The latter two compounds were found at low levels in only six borings (two of which were background borings) and are believed to laboratory contaminants. A summary of the laboratory data is in the EE/CA (Appendix A). Complete data tables are in Appendix B. A full discussion of the data can be found in the RI report.

The highest concentrations of volatile organic compounds were detected in samples from varying depths (2 to 8 feet) in the fill of the Ash Landfill and immediately northwest of this filled area, near the bend in the road. The highest concentration of volatile organic compounds (669,000 μ g/kg of mostly TCE) was found in the 2 to 4 foot sample in B15-91 (Figure 2-4). Generally, concentrations of total volatile organic compounds decrease in a westward direction between boring B15-91 and B25-91 (on the western side of wetland B).

Notes:

¹⁾ vs = volt seconds as measured on the gas chromatograph

The highest concentrations of total volatiles from two borings in the central-western portion of the Ash Landfill (B10-92 and B31-91) ranged from 1,600 to 1,700 μg/kg (Figure 2-4).

The western portion of the Ash Landfill and areas near the bend in the road and wetland B were determined to be the source areas for volatile organic compounds.

A comparison of VOCs (including 1.2-DCE and TCE) in selected soil samples from borings at areas of high soil gas is presented in Table 2-3. In most instances when VOCs are found in the soil gas they are also found in the soil, supporting the use of soil gas techniques to locate source areas for volatile organic compounds.

Semivolatile organics compounds were detected in 23 borings on the site, though many of these borings were not located near the bend in the road area which is the subject of this removal action. Data summary tables are included in the EE/CA (Appendix A). The highest total semivolatile concentrations and widest variety of compounds were found in samples from B4-91 and B7-91. B4-91 is located in the north-westernmost debris pile and B7-91 is located in the Non-Combustible Fill Landfill which are not part of this removal action.

Borings in the Ash Landfill and in the area near the bend in the road, near wetland B, generally contain semivolatiles from the surface to the bottom of the boring, although the concentrations in this area are not as high as those from the debris pile and Non-Combustible Fill Landfill. Detectable concentrations of semivolatiles from this area range between 61 $\mu g/kg$ in borings B28-91 and 31,970 $\mu g/kg$ in B10-91. The highest concentration of semivolatiles in this area are from two borings, B10-91 and B31-91.

Five pesticides and two PCBs were detected in several soil samples on-site. The pesticides include heptachlor, dieldrin, 4,4'-DDE, 4,4'-DDD, and 4,4'-DDT. The PCBs are Aroclor-1242 and Aroclor-1260. Relatively low concentrations of pesticides (18 to 250 µg/kg) were found in borings B10-91, B15-91, B17-91, B30-91 and B31-91. The compounds 4,4'-DDE, 4-4'-DDD and 4,4-DDT are the most common pesticides found on-site, but of these, 4,4'-DDE is the most widespread. The highest concentration of total pesticides was found in B15-91 which had a concentration of 250 μg/kg (exclusively 4,4'-DDE).

PCBs, Aroclor-1242 and 1260, were found only in borings B2-91, B15-91, B28-91, B30-91 and B31-91 located in the Ash Landfill and the immediately to the northwest of the fill near the bend in the road. The highest total PCB concentration (1,000 μg/kg of Aroclor 1242) was

Concentrations for soil analyses are ug/Kg

Concentrations for soil gas analyses are in ppmv

detected in the 2 to 4-foot sample in boring B31-91. Aroclor 1260 is prevalent from the surface to 8 feet below the land surface in borings B2-91 and B15-91, located near the northern extent of the Ash Landfill.

Three herbicides 2,4-DB, MCPP, and 2,4,5-TP (Silvex) were detected in a few samples on the site, however, 2,4-DB and MCPP are more prevalent. These herbicides are found only in locations where dumping of suspected solvents, debris and ash has taken place on the site. Specifically, they were found in suspected solvent dump areas, in all three borings in and near the three debris piles, and in the Ash Landfill area. The highest concentrations of 2,4-DB, MCPP, and 2,4,5-TP (Silvex), detected near the bend in the road area were 410 μ g/kg (at B29-91), 13,000 μ g/kg (at B10-91), and 10 μ g/kg (at B10-91), respectively.

2.1.4.3 Groundwater

As with the soil samples, volatile organic compounds were the primary contaminants of concern detected in the groundwater at the site. These compounds were detected in nine of the 31 monitoring wells sampled on and off-site. The VOCs detected included TCE, 1,2-DCE (total), vinyl chloride, chloroform, 2-Butanone, xylene (total), methylene chloride, and acetone. The latter two compounds are believed to be laboratory contaminants in most instances. TCE and 1,2-DCE are the dominant volatile organics on the site.

The geographic distribution of total volatile organic compounds is shown in Figure 2-5. Ten (10), 100, 1,000, 10,000 and 100,000 μ g/L isocontours define a total volatiles plume that originates in the western portion of the Ash Landfill and extends to the west in the direction of groundwater flow.

TCE is considered as the dominant volatile organic compound on-site. Concentrations of TCE, up to 37,000 and 11,000 μ g/L in the source area (MW-44 and PT-18 respectively) and as low as 4 and 1 μ g/L near the western boundary of the site. Though these concentrations are high, they are well below the TCE solubility (1,100 mg/l at 20°C), and the presence of dense non-aqueous phase liquids (DNAPLS) is unlikely. No DNAPLs have been observed in any of the wells or borings on-site.

Several daughter products of the breakdown of TCE have been observed at the site. They include 1,2-dichloroethylene (1,2-DCE) and vinyl chloride.

May, 1994 Page 2-16 At the downgradient, western end of the plume, 1,2-DCE is the dominant volatile organic compound where it is found at 100 and 71 μ g/L in wells PT-24 and MW-29, respectively. The shift from TCE as the predominant volatile organic compound near the source areas to the dominance of the breakdown daughter compound 1,2-DCE at downgradient locations is consistent with the environmental chemistry of TCE.

No semivolatile organic compounds, pesticides, PCBs, or herbicides were detected in any of the well samples collected on and off-site.

Both unfiltered (total) and filtered (dissolved) groundwater samples were collected. Generally, filtered metals concentrations are less than concentrations in unfiltered samples, with most metals concentrations below the detection limit in the filtered samples.

Some of the highest unfiltered metals concentrations were obtained in well, PT-26, near the Seneca airfield. PT-18 in the Ash Landfill also exhibits some high unfiltered concentrations of metals, including lead (17.8 μ g/L), zinc (496 μ g/L), manganese (1,530 μ g/L) and mercury (0.42 μ g/L). Concentrations of barium, beryllium, cadmium, chromium, lead, manganese, vanadium and zinc occur in unfiltered samples from wells MW-29 and MW-31.

Cyanide concentrations (unfiltered only) were all below the detection limit except in PT-10 where 11.2 μ g/L (just above the detection limit) were detected.

2.1.4.4 Test Pits

Several test pits were dug in and around the landfill in locations where GPR characterization of EM-31 anomalies indicated a possible pipe or drum signature. Five excavations were performed on the Non-Combustible Fill Landfill, and five test pits were performed in and around the Ash Landfill. Test pits completed in the bend in the road area were TP-6 and TP-7.

Test pits were excavated to up to five feet deep using a backhoe. Upon completion all excavated material was returned to the pit and covered. Test pit logs are included in the RI report.

The logs from TP-6 and TP-7 indicate that the debris is mainly in the 0.5 to 4-foot range in the soil. About 0.5 feet of topsoil covers the debris, and 3 to 5 feet of soil lie between the

May, 1994 Page 2-18

bottom of the debris and the top of the shale bedrock. Much of the debris is scattered within the soil cover in the 0.5 to 4 foot range.

2.1.5 Contamination Assessment Summary

As discussed, the primary constituents of concern at the site are TCE and DCE. These are the most prevalent compound in the soil, and the major analytes present in the groundwater. Impacts from other chemicals such as the petroleum residues, PCBs, pesticides, and herbicides appears to be limited to a small area near the bend in the road, since these compounds were generally found in only a few samples.

The focus of this removal action will be to mitigate the impacts of TCE and DCE since these are the main groundwater contaminants, and since these compounds were found in almost all of the soil samples collected at the bend in the road. The goal of this removal action is to remove the source of groundwater contamination. The other constituents at the site will be addressed in the RI/FS process, which will include a baseline risk assessment.

After the soil headspace survey was completed, eight soil borings were collected just outside the two areas identified by the soil headspace survey as the primary source of the volatile organics. The locations of these eight borings are shown on Figure 2-4. While there were volatile organics present in several of the soil samples collected from these borings, the concentrations were generally well below the soil treatment criteria (see Section 3). In fact, only one soil sample had a concentration greater than the soil cleanup objective concentration. The soil headspace survey was effective in delineating the source area of the volatile organic contamination.

2.1.6 National Priorities List Status

The SEDA is included on the federal facilities National Priorities List (NPL). This facility was first listed July 13, 1989.

2.2 **ACTIONS TO DATE**

2.2.1 **Previous Actions**

To date, activities at the site have been limited to investigative tasks. No remedial actions

May, 1994 Page 2-19 have been implemented at the Ash Landfill as part of the IRP. The previous investigations are summarized below and described in detail in the RI.

2.2.2 Army Pollution Abatement Program Study (USAEHA 1979)

The goal of this study was to determine the extent of leachate production and the impacts caused by activities at the Ash Landfill site. The study included installation and sampling of six (6) monitoring wells. The study concluded that groundwater samples from the wells adjacent to the two disposal areas showed evidence of leachate. Maximum contaminant levels for drinking water supplies as defined in the New York State Sanitary code were exceeded for sulfate and color. It was also concluded that these contaminants affect aesthetic quality, but did not represent a health hazard. Maximum contaminant levels were not exceeded for wells downgradient from these wells. Recommendations were made to establish a monitoring program for leachate.

2.2.3 <u>Installation Assessment Report (USATHAMA 1980)</u>

Areas of known or suspected waste disposal at SEDA were delineated in an Installation Assessment (1980) performed by USATHAMA. The investigation included a records search and interviews with current and former SEDA employees. The report identified the Ash Landfill site as having potential for contaminant migration.

Between 1980 and 1987 USAEHA installed five additional groundwater monitoring wells in the area of the Ash Landfill. The wells were installed to investigate the possibility of leachate entering the groundwater. It was reported that several indicator parameters (i.e., sulfate, chloride, specific conductance) were found in the groundwater samples collected from these wells indicating that the landfill had impacted the groundwater quality. Groundwater monitoring results (1986) submitted by USAEHA found that total organic halogens (TOX) was present in a downgradient well on the Ash Landfill site.

2.2.4 Evaluation of SWMU's (USAEHA 1987)

In July 1987, a Groundwater Contamination Survey, was conducted by USAEHA to identify, describe, and evaluate solid waste management units at SEDA. The Ash Landfill site was identified in this report as having a potential for impacting groundwater. Groundwater samples collected in March 1987 contained TCE and 1,2-DCE. It was speculated that these

May, 1994 Page 2-20

compounds were probably not due to the Ash Landfill contents but more likely associated with the refuse burning pits. Groundwater samples from three off-site wells located less than a quarter mile downgradient from the contaminated monitoring wells did not contain volatile organic compounds.

2.2.5 Quarterly Groundwater Monitoring (1987-Present)

Quarterly monitoring of the wells at the Ash Landfill was conducted from 1987 through the present. The study concluded that a plume with two main constituents, TCE and 1,2-DCE, was present. Compounds such as chloroform, 1,2-dichloroethane, and vinvl chloride were also detected. Subsequent groundwater sampling events from January 1990 through the present have confirmed the presence of these volatile organic compounds in the selected wells on the Ash Landfill site.

2.2.6 Geohydrologic Study (USAEHA 1987)

Soil samples were collected from eleven (11) soil borings during the USAEHA October 1987 study. Several volatile organic compounds were detected in these samples including TCE, 1-2-DCE and vinyl chloride. The highest concentration of volatile organics was detected in BH-29, approximately 300 feet north of the incinerator building.

2.2.7 RI/FS (USATHAMA 1989)

ICF (1989), retained by USATHAMA, undertook a Phase I Remedial Investigation (RI) of the landfill area for USATHAMA from September 1988 to February 1989. The scope of the site investigation included the following:

- 1. Soil sampling within the landfill area for volatile and metals analyses:
- 2. Groundwater sampling from 10 existing wells for volatile and metals analyses;
- 3. Surface water sampling;
- 4. Slug testing on several of the existing wells;
- 5. A soil-gas investigation; and
- 6. Terrain conductivity surveys using low-frequency electromagnetic (EM) induction and ground-penetrating radar (GPR).

The results of the investigation are discussed in the RI, in the EE/CA (Appendix A) and above. In general, the investigation indicated that the landfill contained fill materials and

May, 1994 Page 2-21 numerous buried metal debris. Volatile chlorinated compounds such as TCE, trans-1,2-DCE, and chloroform were detected in the soils. Metals were detected in the soils. Groundwater within the landfill contains volatile chlorinated hydrocarbons at levels that appear to have caused the formation of a downgradient plume extending at least to the western limits of SEDA property. The groundwater was investigated only in the shallow aquifer extending down to competent bedrock at a depth of approximately 10 feet below land surface (ft-bls.) The results of the investigation also indicated the potential presence of additional source areas to the north of the projected limits of the landfill.

2.2.8 RI/FS (MAIN/ES, 1990 through present)

In 1990, Chas. T. Main, Inc. (MAIN), retained by the COE, implemented an RI Workplan. The environmental division of MAIN became the Boston office of ES, a sister company of the Parsons Corporation in 1991. These techniques were used to further refine the magnitude of the contamination present, and to provide data to be used for the feasibility study. Much of the work conducted for the Phase II is described in the PSCR. The RI/FS report is currently in preparation.

2.3 STATE AND LOCAL ACTIONS TO DATE

There have been no related state or local actions to date at the SEDA Ash Landfill. However, state and local authorities have been active in reviewing the RI work plans and reports, and have provided oversight for the field work.

2.4 POTENTIAL FOR CONTINUED STATE/LOCAL RESPONSE

There are no known plans for state or local response at the site. The removal action proposed in this action memorandum will be conducted by the Army. State authorities will continue to be given the opportunity to review and comment on site documents.

May, 1994 Page 2-22

3.0 THREATS TO PUBLIC HEALTH, WELFARE OR THE ENVIRONMENT; STATUTORY AND REGULATORY AUTHORITIES

The removal action program discussed in this action memorandum is proposed to address the potential threats discussed below.

3.1 THREATS TO PUBLIC HEALTH OR WELFARE

The contamination at the SEDA Ash Landfill poses a threat to public health or welfare through several mechanisms. The primary threat is through exposure to contaminated groundwater. TCE and its breakdown products are already present in the groundwater, and the contamination plume is believed to have migrated off the site. The presence of TCE and other contaminants in the soil also pose a potential threat of airborne exposure through volatilization or airborne particulate matter. Finally, the contaminated soil may pose a threat through soil exposure to SEDA post personnel, or to the general public in the future should the post property be opened to public use. The risk assessment conducted as part of the RI indicates that the volatiles in groundwater pose a significant threat to human health. The risks posed by the other constituents (i.e., metals, semi-volatile organics) all fall within the acceptable ranges defined by EPA. Tables 2-5 and 2-7 in the EE/CA (Appendix A) summarize the analytical results for the soil samples collected in the "bend in the road" area as part of the RI. These tables include results for volatile and semivolatile organic compounds, and metals.

3.2 THREATS TO THE ENVIRONMENT

The threats to the environment posed by the site have not been quantified. It is believed that there is a threat of exposure through the air pathway or soil exposure to the significant animal population on the site. In addition, surface water contamination from site runoff or groundwater surface water contamination poses a threat to aquatic life.

3.3 STATUTORY AUTHORITY

Authority for responding to releases or threats of releases from a hazardous waste site is addressed in section 104 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980, as amended. The Army has been delegated the response authority for Army sites, whether or not the sites are on the National Priorities List of the

May, 1994 Page 3-1

U.S. Environmental Protection Agency (EPA). Under CERCLA section 104(b), the Army is authorized to investigate, survey, test, or gather other data required to identify the existence, extent, and nature of contaminants, including the extent of danger to human health or welfare and the environment. In addition, the Army is authorized to undertake planning, engineering, and other studies or investigations appropriate to directing response actions that prevent, limit, or mitigate the risk to human health or welfare and the environment.

3.4 ADDITIONAL JUSTIFICATION FOR REMOVAL ACTION

In addition to potential risks identified above, the following justification is offered for the proposed removal action:

The State of New York has established cleanup criteria for remediation of contaminated soils. Those guidelines indicate that remediation is appropriate for this site since several constituents, most notably TCE and DCE exceed these criteria.

Upon completion of the removal action, the site would still be subjected to further investigatory activities within the CERCLA process to confirm acceptable cleanup, or to determine the requirement for additional remedial actions.

May, 1994 Page 3-2

4.0 ENDANGERMENT DETERMINATION

Actual or threatened releases of pollutants and contaminants from this site, if not addressed by implementing the response action selected in this action memorandum, may present an endangerment to public health, welfare, or the environment.

May, 1994 Page 4-1

5.0 PROPOSED ACTIONS_AND ESTIMATED COSTS

5.1 PROPOSED ACTIONS

5.1.1 General Statement of the Removal Action Objectives

The establishment of action objectives and site-specific considerations forms a basis for identifying and selecting appropriate action alternatives. Action objectives must:

- Protect human health and the environment
- Address contaminants of concern, exposure routes, and receptors.

Applicable or relevant and appropriate requirements (ARARs) establish cleanup standards that can be used to define action objectives.

Several general objectives can be defined for the proposed action at the SEDA Ash Landfill. The primary objective is to eliminate the threat of continued groundwater contamination by removing the source of the contamination. Secondary objectives include completing all remedial activities on site, and in a manner which minimizes exposure to workers and the general public during the remedial activities.

5.1.2 Proposed Action Description

This section provides a brief summary of the removal action program and thermal desorption, the primary technology proposed for the removal action. A more detailed discussion appears in the EE/CA (Appendix A).

The area to be remediated is highlighted in Figure 5-1. This area was determined during the soil headspace survey conducted by ES in April 1993. Confirmation of this area was obtained by the collection of eight soil borings, as described in Section 2. Areas outside the contours defined by the soil headspace survey were shown not to contain TCE, DCE, or vinyl chloride in excess of the NYSDEC SCGs.

May, 1994 Page 5-1

The removal action will be conducted in several steps. Figure 5-2 is a blockflow diagram highlighting key process steps. First, the soil and debris will be excavated, and the material stockpiled. Sheet piling will be used to control groundwater inflow and provide excavation stability. Soil samples will be collected from the bottom and sides of the excavation and analyzed for volatile and semivolatile organics in order to ensure that no soil remaining in the ground exceeds the NYSDEC soil cleanup criteria. The stockpiled material will then be sized. and material too large to pass through the thermal desorption unit will be segregated. The large material will then be washed in a debris washing area. After being washed, the debris will be sent off-site to an approved nonhazardous waste landfill. The washwater will be collected and either treated to meet SPDES requirements and discharged on-site, or shipped off-site to a permitted TSD facility.

The material which is small enough for the thermal desorption unit will be passed through the treatment unit. The temperature in the unit will be maintained at a minimum of 400°F. The treated soil will be stockpiled after passing through the unit, and allowed to cool prior to sampling. If the treated material passes the post-treatment sampling, it will be ready to be backfilled. Any soil which fails the post-treatment sampling will be reprocessed. The treated soil will be analyzed for volatiles and semivolatile organics, and will be sampled at a rate of one sample per every 100 cubic yards of soil. During the initial proveout period, the sample rate will be one sample per every 20 to 30 cubic yards of soil.

The offgas from the treatment unit will pass through several treatment units. The exact type and order of these units will vary depending on the contractor, but in general there will be an organic treatment unit and a particulate treatment unit. The organic treatment unit will likely be an afterburner, or a catalytic or thermal oxidizer. Particulate control will likely consist of a baghouse.

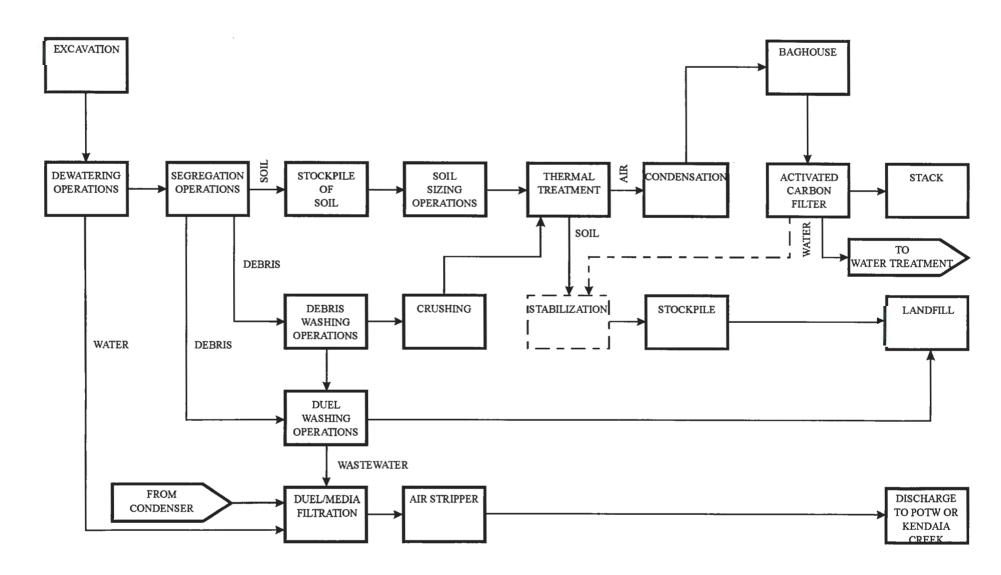

The treated soils will be backfilled into the excavation. Clean fill will be brought on site to account for the debris sent off site and any other volume reductions which may occur during treatment. The site will be brought to grade, and seeded with native vegetation.

5.1.3 Contribution to Remedial Performance

The purpose of this action is to remove the source of TCE and DCE contamination at the site and thereby reduce the potential for further contamination of soils and groundwater. While not the primary concern of the removal action, other organics present at the site, including semivolatiles can be treated by thermal desorption. This technology should minimize the potential for future remedial actions.

May, 1994 Page 5-3

Thermal Desorption Blockflow Diagram

^{*} AS AN ALTERNATE CATALYTIC OXIDATION COULD BE USED

5.1.4 Description of Alternative Technologies

The NCP requires that alternative technologies (technologies which are not land disposal) be evaluated. Two treatment technologies which are alternative technologies to land disposal were evaluated in detail for potential use at the SEDA Ash Landfill. These were thermal desorption and incineration, two technologies which use heat to treat volatile organic contamination. Offsite disposal, which was also evaluated in detail is considered a land disposal technology. A complete description of these technologies, along with the rationale for selecting Low Temperature Thermal Desorption is in the EE/CA (Appendix A).

5.1.5 Engineering Evaluation/Cost Analysis

In order to determine the appropriate remedial technology for the SEDA Ash Landfill, an EE/CA was conducted. The EE/CA is included as Appendix A of this report. The EE/CA contains a brief summary of the site history and the results of previous investigations.

The main focus of the EE/CA is an evaluation of the different remedial technologies. A number of technologies were considered, with thermal desorption, SVE, incineration, and offsite disposal evaluated in detail. A complete discussion of the evaluation process is included in the EE/CA (Appendix A). A brief overview of thermal desorption is provided above.

5.1.6 Institutional Controls

There are no institutional controls required for this action. The requirement for institutional controls will be addressed as part of the overall remedial action.

5.1.7 Off-Site Disposal Policy

It is anticipated that no materials classified as hazardous waste will be generated during this removal action. All nonhazardous waste (construction debris, etc.) will be disposed in an approved nonhazardous waste landfill.

5.1.8 Post-Removal Site Control Activities

The depot is fenced and patrolled by armed guards to limit access.

May, 1994 Page 5-5

5.1.9 OA/OC Plan

The remedial contractor will be required to develop a QA/QC plan which will be submitted to the appropriate agencies for approval. This plan will address both detailed and broad QA/QC issues. Detailed requirements include sampling and analytical protocols. The broader aspects will address the procedures necessary to ensure that the excavation, sizing, debris washing, and thermal desorption procedures are conducted for accordance with the specifications.

Additional QA/QC will be provided by a 3rd party oversite contractor. The oversight contractor will be responsible for monitoring the removal action activities, including taking confirmation soil samples.

5.2 ARARs

Pursuant to section 300.415(i) of the NCP, the removal action for the site "shall, to the extent practicable considering the exigencies of the situation, attain applicable or relevant and appropriate requirements under federal environmental or state environmental or facility siting laws." ARARs are used to identify removal action objectives, formulate removal action alternatives, govern the implementation and operation of a selected removal action, and evaluate the appropriate extent of site cleanup.

In 40 CFR 300.5 EPA defines applicable requirements as those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Only those state standards that are identified by a state in a timely manner and that are more stringent than federal requirements may be applicable. Relevant and appropriate requirements are defined as those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that, while not "applicable" to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site. Only those state standards that are identified in a timely manner and are more stringent than federal requirements may be relevant and appropriate.

May, 1994 Page 5-6

Any standard, requirement, criterion, or limitation under any federal environmental or state environmental or facility siting law may be either applicable or relevant and appropriate to a specific action. The only state laws that may become ARARs are those promulgated such that they are legally enforceable and generally applicable and equivalent to or more stringent than federal laws. A determination of applicability is made for the requirements as a whole, whereas a determination of relevance and appropriateness may be made for only specific portions of a requirement. An action must comply with relevant and appropriate requirements to the same extent as an applicable requirement with regard to substantive conditions, but need not comply with the administrative conditions of the requirement.

Three categories of ARARs have been analyzed: chemical-specific, location-specific, and action-specific. Chemical-specific ARARs address certain contaminants or a class of contaminants and relate to the level of contamination allowed for a specific pollutant in various environmental media (water, soil, air). Location-specific ARARs are based on the specific setting and nature of the site. Action-specific ARARs relate to specific actions proposed for implementation at a site, include low temperature thermal desorption for the treatment of soils, filtration and carbon adsorption for the treatment of groundwater and carbon adsorption of catalytic incineration for the treatment of air. A full discussion of the potential ARARs for this removal action are in the EE/CA (Appendix A). Listed below are the ARARs specific to the selected technology.

5.2.1 Chemical-Specific ARARs

Chemical-specific ARARs are usually health or risk-based standards limiting the concentration of a chemical found in or discharged to the environment. They govern the extent of site remediation by providing actual cleanup levels, or the basis for calculating such levels for specific media. These requirements also apply to air emissions during the removal action. A number of federal and state regulations may be used for this site. These include the following:

Air Quality

 40 CFR part 50.12 (applicable): Ambient Air Quality Standard for Lead. Lead concentrations in the ambient air shall not exceed 1.5 micrograms lead per cubic meter of air, 90-day average.

May, 1994 Page 5-7

- 40 CFR part 50.6 (applicable): Ambient Air Quality Standard for PM-10. PM-10 concentrations in the ambient air shall not exceed the following: 24—hour average, 150 micrograms per cubic meter of air; annual average, 50 micrograms per cubic meter of air.
- 40 CFR part 61 (applicable and relevant and appropriate): National Emission Standards for Hazardous Air Pollutants. This regulation requires the minimization of emissions, specifies emissions tests and monitoring requirements, and sets limits on several hazardous air pollutants.
- 40 CFR part 58 (applicable): Ambient Air Quality Surveillance. This part defines quality assurance requirements, monitoring methods, instrument siting, and operating schedule for ambient air quality surveillance.
- 40 CFR part 52 (applicable): Approval and Promulgation of Implementation Plans. This part defines general provisions for the contents of state implementation plans (SIPs).
- 6 NYCRR part 256 (applicable): Air Quality Classification System. This regulation defines four general levels of social and economic development for geographical areas in New York. SEDA is Level II.
- 6 NYCRR subpart 257-1 (applicable): Air Quality Standards General.
- 6 NYCRR subpart 257-3 (applicable): Air Quality Standards-Particulates. Suspended particulates shall not exceed 250 mg/m³ more than once a year. Annual standard -55 $\mu g/m^3$, 30-day standard - 100 $\mu g/m^3$, 60-day standard - 85 $\mu g/m^3$, 90-day standard - 80 μg/m³, standard for settleable solids - 50 percent of the values of the 30 day average concentrations shall not exceed 0.30 mg/cm²/mo; - 84 percent shall not except 0.45 mg/cm²/mo.
- 6 NYCRR subpart 257-6 (applicable): Air Quality Standards Hydrocarbons (non methane). Three hour standard measured from 6 to 9 am - 0.24 ppm.

Page 5-8 May, 1994

NYSDEC Air Guide - 1 (TBC): This document provides guidance for the control of toxic ambient air contaminants in New York state including guidance on the following contaminants of concern.

Trichloroethene - 33,000 µg/m³ SGC; 4.5 E-01 µg/m³ AGC Dichloroethene - 14,000 μg/m³ SGC; 1900.0 μg/m³ AGC Vinvl Chloride - 1300 μ g/m³ SGC; 2.0 E -02 μ g/m³ AGC

Water Quality

There are a number of water quality standards which are potential ARARs for this removal action. These are summarized in Table 3-1 of the EE/CA (Appendix A) and described below.

- 40 CFR part 131 (applicable): Water Quality Standards. This part implements section 101 of the Clean Water Act (CWA), which specifies the national goals of eliminating the discharge of pollutants, prohibiting the discharge of toxic pollutants in toxic amounts, and implementing programs for control of nonpoint sources.
- 40 CFR part 131.12 (applicable): Antidegradation Policy. Establishes standards to prevent a body of water which has an existing high standard from degrading to a lower standard.
- 40 CFR part 141 (applicable): National Primary Drinking Water Regulations. This part establishes primary drinking water regulators pursuant to Section 1412 of the Public Health Service Act as amended by the Safe Drinking Water Act.
- 40 CFR part 141.11 (applicable): Maximum Inorganic Chemical Contaminant Levels. This section establishes maximum contaminant levels (MCLs) for inorganic chemicals including the following:

Constituent	Level mg/L
Arsenic	0.05
Barium	1.0
Cadmium	0.010
Chromium	0.05
Lead	0.05

May, 1994 Page 5-9

Mercury	0.002
Selenium	0.01

40 CFR part 141.12 (applicable): Maximum Organic Chemical Contaminant Levels. This section establishes MCLs for organic chemicals including the following:

Constituent	<u>Level mg/L</u>
TCE	0.005
Benzene	0.005
Total trihalomethanes	0.10

- 40 CFR part 264 subpart F (relevant and appropriate): Releases from Solid Waste Management Units. Standards for protection of groundwater are established under this citation.
- 40 CFR Part 403 (applicable): Pretreatment Standards for the Discharge of Treated Site Water to a Publicly Owned Treatment Works (POTW). This part establish pretreatment standards for the discharge of wastewater to POTWs.
- 6 NYCRR Chapter X (relevant and appropriate): This chapter establishes the requirements of the State Pollutant Discharge Elimination System.
- 6 NYCRR Subparts 701 and 702 (applicable): These subparts establish surface water standards for protection of drinking water and aquatic life.
- 6 NYCRR Subpart 703 (applicable): This subpart establishes groundwater standards specified to protect groundwater for drinking water purposes.
- 6 NYCRR Subpart 375 (relevant and appropriate): This subpart contains the New York State rules for inactive hazardous waste disposal sites.
- 6 NYCRR Subpart 373-2.6 and 373-2.11 (applicable): This regulation requires groundwater monitoring for releases from solid waste management units.

May, 1994 Page 5-10

- 6 NYCRR Subpart 373-2 (relevant and appropriate): This regulation establishes
 postclosure care and groundwater monitoring requirements.
- 10 NYCRR Part 5 (relevant and appropriate): This regulation establishes criteria for drinking water supplies. Specifically, the NYSDOH MCL for lead is 0.015 mg/L.
- NYSDEC Tags 1.1.1 (relevant and appropriate): This document compiles water quality standards and guidance values for use in NYSDEC program.

Soil Quality

• 6 NYCRR Subpart 375 (relevant and appropriate): This subpart contains the New York State rules for inactive hazardous waste disposal sites. Specifically, cleanup levels for hazardous constituents in soil have been proposed by the State of New York (NYSDEC TAGM #HWR-92-4046). The primary chemicals of concern at the SEDA Ash Landfill for this removal action are chlorinated hydrocarbons, specifically TCE, DCE, and vinyl chloride, though several other compounds exceed the target cleanup levels. For this project, the following TAGM values apply:

TCE 0.7 mg/kg DCE 0.3 mg/kg

• 40 CFR 268 Land Disposal Requirements (applicable). These regulations provide the treatment requirements for land disposal of hazardous wastes. Since the wastes are potentially TC hazardous due to concentrations of TCE and lead, treatment standards for D008 (lead) and D040 (TCE) may apply. Soils can be tested to determine if the TCLP extracts exceed the regulatory limits of 5.0 mg/L for lead and 0.5 mg/L for TCE. It should be noted that soils meeting the TCE TAGM of 0.7 mg/kg will have a maximum TC extract concentration of 0.035 mg/L, which is well below the TC regulatory limit.

5.2.2 Location-Specific ARARs

Location-specific ARARs govern natural site features such as wetlands, floodplains, and sensitive ecosystems, and manmade features such as landfills, disposal areas, and places of historic or archaeological significance. These ARARs generally restrict the concentration of hazardous substances or the conduct of activities based solely on the particular characteristics

May, 1994 Page 5-11

or location of the site. Federal and State regulations which may apply to this removal action include the following:

Endangered Species

40 CFR part 257.3-2 (relevant and appropriate): Facilities or practices shall not cause or contribute to the taking of any endangered or threatened species.

Location Standards

- 40 CFR part 264.18 (relevant and appropriate): Location Standards for Hazardous Waste Facilities. The general requirements for locating a hazardous treatment, storage, or disposal facility are found in this section. They include provisions for seismic considerations and floodplains.
- 40 CFR part 241.202 (applicable): Site selection shall be consistent with public health and welfare. It shall also be consistent with land-use plans and air and water quality standards.

Antiquities

- 16 USC part 469a-1 (applicable): The Archaeological and Historic Preservation Act requires that action be taken to recover and preserve artifacts.
- 36 CFR part 800 (relevant and appropriate): Action must be taken to preserve historic properties. Actions must be planned to minimize harm to national historic landmarks.

5.2.3 Action-Specific ARARs

Action-specific ARARs are usually technology- or activity-based- limitations that control actions at hazardous waste sites. Action-specific ARARs generally set performance or design standards, controls, or restrictions on particular types of activities. To develop technically feasible alternatives, applicable performance or design standards must be considered during the development of all removal alternatives. Action-specific ARARs are applicable to this site. The action-specific ARARs to be used will be determined by the Army based upon the technology chosen. Federal and State regulations which may apply include the following:

May, 1994 Page 5-12

Solid Waste Management

There should be very little solid waste generated as a result of this removal action. One possible waste would be spent carbon canisters. The remedial contractor would be responsible to dispose or regenerate the canisters off-site.

Hazardous Waste Management

No hazardous wastes should be generated as a result of this action; however, if hazardous wastes were generated, they would be disposed of in accordance with 40 CFR Parts 264 and 265.

 40 CFR 268 Land Disposal Restrictions (applicable). These regulations provide the requirements for land disposal of the treatment residuals from the treatment of hazardous waste.

Occupational Health and Safety Administration

• 29 CFR part 1910.50 (applicable): Occupational Noise. No worker shall be exposed to noise levels in excess of the levels specified in this regulation.

Transportation of Hazardous Waste

- 40 CFR 268 (applicable). This section contains the notification requirements for transport of land-disposal restricted wastes.
- 49 CFR Part 171 (applicable): General information, regulations, and definitions. This regulation prescribes the requirements of the DOT governing the transportation of hazardous material.
- 40 CFR Part 172 (applicable): Hazardous materials table, special provisions, Hazardous Materials Communications, Emergency Response Information, and Training requirements. This regulation lists and classifies those materials which the DOT has designated to be hazardous materials for the purpose of transportation and prescribes the requirements for shipping papers, package marking, labeling and transport vehicle placarding applicable to the shipment and transportation of those hazardous materials.

May, 1994 Page 5-13

49 CFR Part 177 (applicable): Carriage by Public Highway. This regulation prescribes
requirements that are applicable to the acceptance and transportation of hazardous
materials by private, common, or contract carriers by motor vehicle.

Incineration

• 40 CFR Part 264 Subpart O and 6 NYCRR Subpart 373-2.15 are not applicable or relevant and appropriate for the catalytic incineration of SVE off-gases.

5.3 PROJECT SCHEDULE

The overall project schedule is shown in Figure 5-2 of the EE/CA. The total duration for the removal action after regulatory approval is several months. It is anticipated that this project will be put out for bid in February 1994 and that removal action will be completed by October 1994.

5.4 ESTIMATED COSTS

The following cost estimate for thermal desorption is based upon a preliminary estimate provided by Canonie which was one of three vendors that provided a cost estimate. A more detailed cost estimate will be prepared in accordance with details and format of the Huntsville Division Design Manual for Architect Engineers. It should be noted that long-term groundwater monitoring is not part of this estimate. Groundwater at the Ash Landfill will be addressed through a separate removal or remedial action.

<u>Task</u> <u>Cost</u>

- 1. Work Plan, Health and Safety Plan
- 2. Permitting, Mobilization
- 3. Offsite Disposal of Spent Carbon
- 4. Site Restoration
- 5. Demobilization

May, 1994

49 CFR Part 177 (applicable): Carriage by Public Highway. This regulation prescribes
requirements that are applicable to the acceptance and transportation of hazardous
materials by private, common, or contract carriers by motor vehicle.

Incineration

 40 CFR Part 264 Subpart O and 6 NYCRR Subpart 373-2.15 are not applicable or relevant and appropriate for the catalytic incineration of SVE off-gases.

5.3 PROJECT SCHEDULE

The overall project schedule is shown in Figure 5-2 of the EE/CA. The total duration for the removal action after regulatory approval is several months. It is anticipated that this project will be put out for bid in February 1994 and that removal action will be completed by October 1994.

5.4 ESTIMATED COSTS

The following cost estimate for thermal desorption is based upon a preliminary estimate provided by Canonie which was one of three vendors that provided a cost estimate. A more detailed cost estimate will be prepared in accordance with details and format of the Huntsville Division Design Manual for Architect Engineers. It should be noted that long-term groundwater monitoring is not part of this estimate. Groundwater at the Ash Landfill will be addressed through a separate removal or remedial action.

- 7. Material Handling
- 8. Thermal Treatment
- 9. Confirmational Sampling
- Air Monitoring 10.

SUBTOTAL (items 6 through 10)	\$2,280,000	
SUBTOTAL	\$2,730,000	
Contingency (10%)	273,000	
Oversight	150,000	
TOTAL	\$3,153,000	

6.0 EXPECTED CHANGE IN THE SITUATION SHOULD ACTION BE DELAYED OR NOT TAKEN

If this removal action is delayed or not taken, several changes in site conditions would occur:

- Some lateral and vertical migration of the contaminants can be expected. The
 migration could occur through several mechanisms, including transport of water-soluble
 constituents through infiltration or runoff. Groundwater at the site is already
 contaminated, and this contamination will likely worsen over time should the source
 remain in the soils.
- The contamination in the soil is likely to migrate slowly over time. Much of the contamination is at or near the water table, and can be carried in the water.

May, 1994 Page 6-1

7.0 <u>OUTSTANDING POLICY ISSUES</u>

This section is not applicable to this removal action since the lead agency for this site is the Army, and not the EPA or NYSDEC.

May, 1994

8.0 <u>ENFORCEMENT</u>

This section is not applicable to this removal action since the lead agency, the Army is the Principle Responsible Party for this site, and is taking responsibility for the removal action.

May, 1994 Page 8-1

9.0 **RECOMMENDATION**

The remedial technique recommended for this site is thermal desorption. This technology has been effective at other sites with similar contamination. In addition, this technology can be implemented quickly, is cost-effective, can treat the other constituents present at the site, and can be completed in a timely manner.

This decision document represents the selected removal action for the Seneca Army Depot Ash Landfill located in Romulus, New York, developed in accordance with CERCLA as amended, and not inconsistent with the NCP. This decision is based on the administrative record for the site.

1.0 **INTRODUCTION**

1.1 PURPOSE, SCOPE, AND OBJECTIVES

This Engineering Evaluation/Cost Analysis (EE/CA) has been prepared for the Ash Landfill site at the Seneca Army Depot (SEDA) by Engineering-Science (ES) in support of the proposed removal action for soils at the SEDA Ash Landfill. ES has been retained by the United States Army Corps of Engineers (USACE) Huntsville Division as part of their remedial response activities under the Comprehensive Environmental Responsibility, Compensation, and Liability Act (CERCLA) to perform these activities.

This report is based on the finding of the remedial investigation (RI) conducted at the SEDA Ash Landfill. Activities conducted as part of the RI included: soil gas surveys, soil borings to gather stratigraphic information, soil samples for analytical testing, construction of piezometers to determine groundwater flow direction, and construction and sampling of overburden and bedrock groundwater monitoring wells.

The purpose of this remedial action is to mitigate the soure of Trichloroethene (TCE) and Dichloroethene (DCE) in the "bend-in-the-road" area adjacent to the Ash Landfill and thereby reduce the chance of further degradation of soils and groundwater. constituents of concern identified in the RI, including metals and PAHs are not the focus on this action.

The removal action will be completed in parallel to the RI/FS process, between the RI and the Feasibility Study (FS). Once this remedial action is complete, this site will return to the RI/FS process. This expidited remedial action is part of an Army approach to streamline the RI/FS process where possible. The outcome of this action will then be incorporated into the final Record of Decision (ROD) document. If following the risk assessment, unacceptable risk remains, additional remedial actions may be considered.

As an expedited FS, the EE/CA is an evaluation of the removal action alternatives for a site. The purpose of the EE/CA is to present the following:

- Assess the study area characteristics and justify the need for a removal action
- Identify removal action objectives

May, 1994 Page 1-1 SENECA ASH LANDFILL FINAL EE/CA

- Identify removal action technologies
- Evaluate removal action technologies
- Propose a removal action which will achieve the removal action objectives.

Additionally, the EE/CA serves as a basis for the action memorandum and the design the removal action. The action memorandum documents the need for a removal action and the decision process leading to a removal action.

The overall objective of a removal action is to eliminate or reduce the threats to human health or to the environment. The primary threat from the soil at this site is the potential for uncontrolled releases of hazardous constituents from the subsoils to the groundwater. The removal and/or proper treatment of these soils are necessary for the protection of human health and the environment.

1.2 STATUTORY AUTHORITY

Authority for responding to releases or threats of releases from a hazardous waste site is addressed in section 104 of CERCLA, as amended. The Army has been delegated the response authority for Army sites, whether or not the sites are on the National Priorities List of the U.S. Environmental Protection Agency (EPA). Under CERCLA Section 104(b), the Army is authorized to investigate, survey, test, or gather other data required to identify the existence, extent, and nature of contaminants, including the extent of danger to human health or welfare and the environment. In addition, the Army is authorized to undertake planning, engineering, and other studies or investigations appropriate to directing response actions that prevent, limit, or mitigate the risk to human health or welfare and the environment.

May, 1994 Page 1-2

2.0 SITE CHARACTERIZATION

2.1 BASE DESCRIPTION AND HISTORY

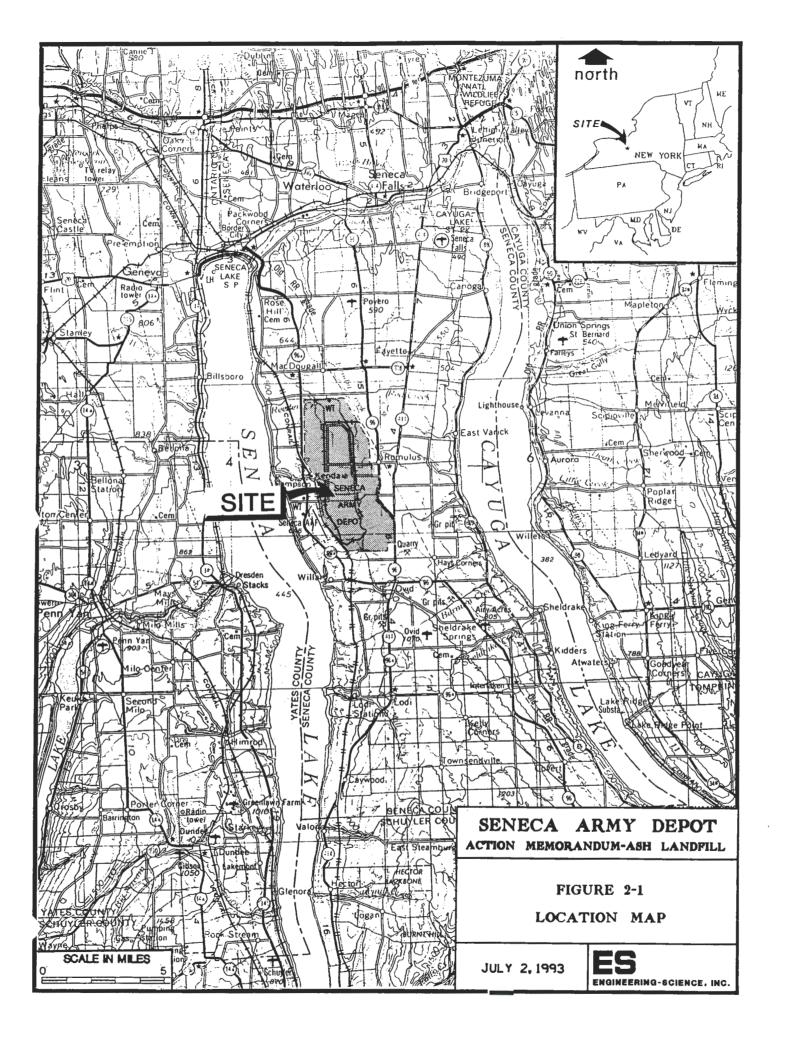

This section provides a brief overview of SEDA and site background information. A more detailed discussion can be found in the RI report (USATHAMA, 1989) and the Remedial Investigation (RI) for the Ash Landfill (ES, 1993).

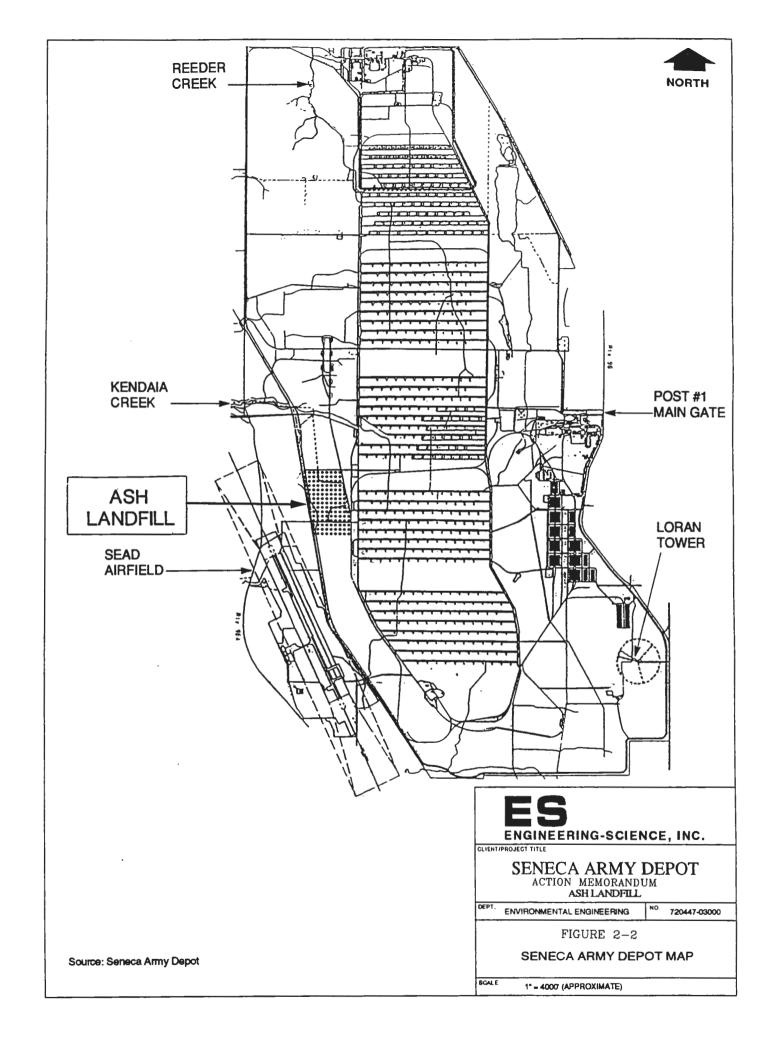

The SEDA facility is situated on the western flank of a topographic high between Cayuga and Seneca lakes in the Finger Lakes region of central New York (Figure 2-1). Within the SEDA is the approximately 130 acre Ash Landfill site, located about 2,000 feet east of the northwestern extension of the SEDA airstrip in the southwestern portion of the 10,587-acre SEDA facility in Romulus, New York (Figure 2-2). The SEDA was constructed in 1941 and has been owned by the United States Government and operated by the Department of the Army since this time. The post generally consists of an elongated central area for storage of ammunitions and weaponry in quonset-style buildings, an operations and administration area in the eastern portion, and an army barracks area at the north end of the depot. The base was expanded to encompass a 1,524-meter airstrip, formerly the Sampson Air Force Base. The mission of the SEDA has been primarily the management of munitions. Currently, SEDA is used for the following purposes: 1) receiving, storing, and distributing ammunition and explosives, 2) providing receipt, storage, and distribution of items that support special weapons and 3) performing depot-level maintenance, demilitarization, and surveillance on conventional ammunition and special weapons. The depot formerly employed approximately 1,000 civilian and military personnel. Within the last year the facility has undergone a downsizing and no longer houses a large contingent of military personnel.

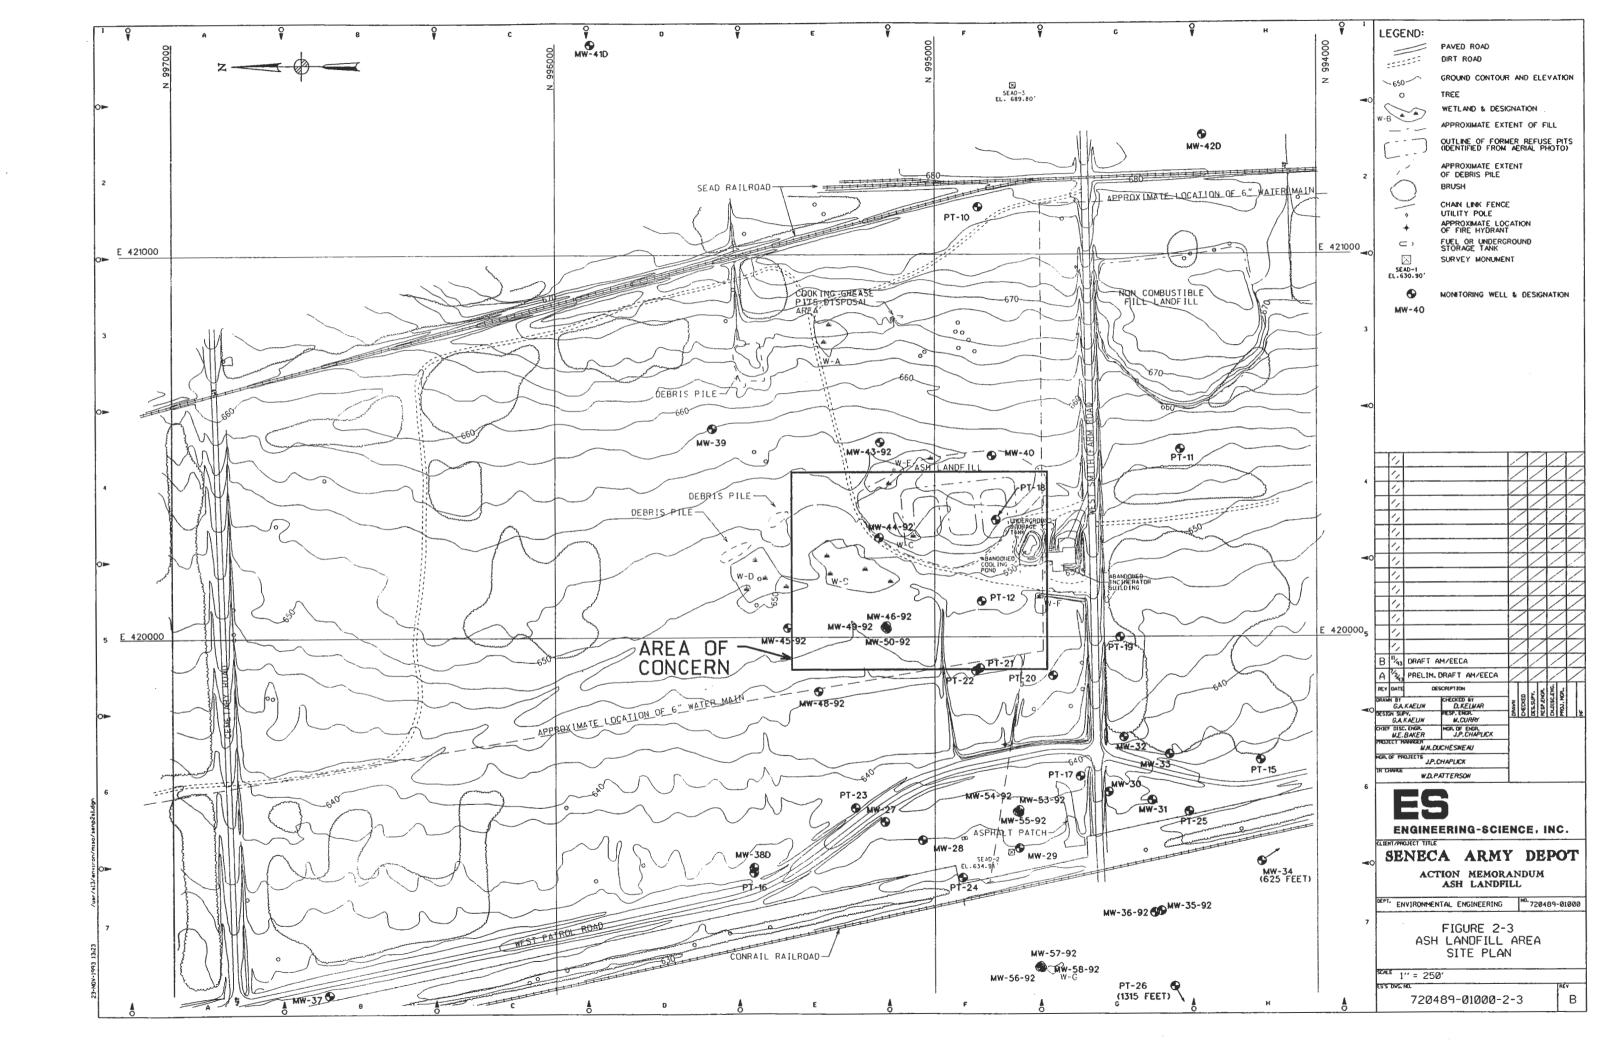

The site consists of an abandoned incinerator building and stack (Building 2207), a former cooling pond, an ash landfill, and a nearby Non-Combustible Fill Landfill (Figure 2-3). The site is bounded on the north by Cemetery Road, on the east by a SEDA railroad line, on the south by undeveloped SEDA land, and on the west by the depot's boundary. Beyond the depot's western boundary are farmland and residences on Smith Farm Road and along Route 96A. Sampson State Park near Seneca Lake is further to the west.

From 1941 to 1974, uncontaminated trash was burned in a series of burn areas east of the abandoned incinerator building. According to the AEHA Interim Final Report, Groundwater Contamination Survey No. 38-26-0868-88 (July 1987), during this same period

Page 2-1 May, 1994

SENECA ASH LANDFILL FINAL EE/CA

of time (1941 until the late 1950's or early 1960's) the ash from the refuse burning areas was buried in the landfill.

The incinerator, built in 1974, was a multiple chamber, batch-fed unit which burned rubbish and garbage. Nearly all of the approximately 18 tons of refuse generated per week on the depot were incinerated. The source for the refuse was domestic waste from depot activities and family housing. Large items which could not be burned were disposed of at the Non-Combustible Fill Landfill. The Non-Combustible Fill Landfill was used from 1969 through 1977.

Ashes and other residues from the incinerator were temporarily disposed of in an unlined cooling pond immediately north of the incinerator building. The cooling pond consisted of an unlined depression approximately 50 feet in diameter and approximately 6 to 8 feet deep. When the pond filled (approximately every 18 months), the fly ash and residues were removed, transported, and buried in the adjacent landfill east of the cooling pond. The refuse was dumped in piles and occasionally spread and compacted. The active area of the Ash Landfill extended at least 500 feet north at the incinerator building near a bend in a dirt road, based on an undated aerial photograph of the incinerator during operation. Parallel grooves at the northernmost extent of the filled area are visible in the aerial view of the incinerator and adjacent fill area during active operation and indicate that the fill was spread using a bulldozer or similar equipment. The incinerator was destroyed by a fire on May 8, 1979, and the landfill was subsequently closed. The landfill was covered with native soils of various thicknesses but has not been closed with an engineered cover or cap.

A grease pit disposal area near the eastern boundary of the site was used for disposal of cooking grease.

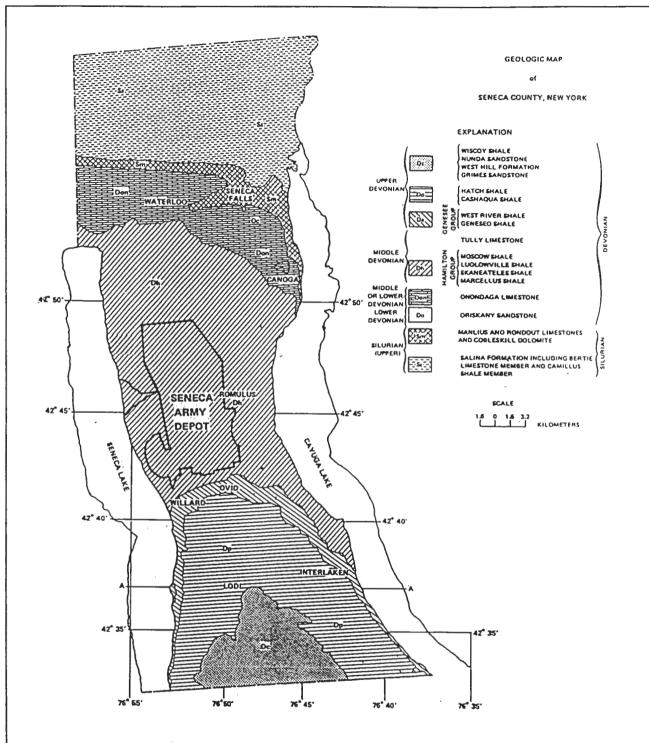

2.2 REGIONAL GEOLOGICAL AND HYDROGEOLOGICAL SETTING

2.2.1 Regional Geology

The Finger Lakes uplands area is underlain by a broad north-to-south trending series of rock terraces mantled by glacial till. As part of the Appalachian Plateau, the region is underlain by a tectonically undisturbed sequence of Paleozoic rocks consisting of shales, sandstones, conglomerates, limestones, and dolostones. Figure 2-4 shows the regional geology of Seneca

May, 1994 Page 2-5

SENECA ARMY DEPOT ACTION MEMORANDUM-ASH LANDFILL

ES ENGINEERING-SCIENCE, INC. SENECA ASH LANDFILL FINAL EE/CA

County. In the vicinity of SEDA, Devonian age (385 million years bp) black shale of the Hamilton group is monoclinally folded and dips gently to the south. No evidence of faulting or folding of the sediments is present.

Pleistocene age glacial till deposits overlie the shales. The till matrix, the result of glaciation, varies locally but generally consists of horizons of unsorted silt, clay, sand, and gravel. In the Finger Lakes region of New York, the till thickness varies from 1 to 50 meters. However, on the till plain between Seneca and Cayuga Lake it is near the surface and generally thin (Muller and Cadwell, 1986). In the central and eastern portions of SEDA the till is thin and bedrock is exposed or within 1 meter of the surface in some locations. The soils at the site are classified as unsorted inorganic clays, inorganic silts, and silty sands. In general, the topographic relief associated with these soils is 3 to 8%.

2.2.2 <u>Regional Hydrogeology</u>

Regionally, four distinct hydrologic units have been identified within Seneca County. These include two distinct shale formations, a series of limestone units, and unconsolidated beds of Pleistocene glacial till. Overall, the groundwater in the county is very hard, and therefore, the quality is minimally acceptable for use as potable water. Approximately 95 percent of the wells are used for domestic or farm supply and the average daily withdrawal is approximately 500 gallons. About 5 percent of the wells in the county are used for commercial, industrial, or municipal purposes. Seneca Falls and Waterloo, the two largest communities in the county, are in the hydrogeologic region which is most favorable for the development of a groundwater supply. Because the hardness of the groundwater is objectionable to the industrial and commercial establishments operating within the villages, both villages utilize surface water as their municipal supplies. The villages of Ovid and

Interlaken, both of which are without substantial industrial establishments, utilize groundwater as their public water supplies. Ovid obtains its supply from two shallow gravel-packed wells, and Interlaken is served by a developed seepage-spring area.

Regionally, the till aquifer would be expected to flow in a direction consistent with the ground surface elevations. Geologic cross-sections from Seneca Lake and Cayuga Lake have been constructed by the State of New York, (Mazola, A.J., 1951 and Crain, L.J., 1974). This information suggests that a groundwater divide exists approximately halfway between the two

May, 1994 Page 2-7

finger lakes. SEDA is located on the western slope of this divide and, therefore, regional surficial groundwater is expected to flow westward toward Seneca Lake.

Most of the groundwater in Seneca County is derived from precipitation that falls on the land surface and percolates into surficial deposits (Mazola, 1951). Three geologic strata have been used to produce water for both domestic and agricultural purposes. These include the following: 1) a bedrock aquifer, which in this area is predominantly shale; 2) an overburden aquifer, which includes Pleistocene deposits (glacial till); and 3) a deep aquifer present within beds of limestone present within the underlying shale.

The geologic information reviewed indicates that the upper portions of the shale formation would be expected to yield small supplies of water which would be adequate for domestic use. For mid-Devonian shales such as those of Hamilton group, the average yields (i.e., less than 15 gpm), are consistent with what would be expected for shales (LaSala, 1968). The deeper portions of the shale formation, have provided yields up to 150 gpm due to the occurrence of limestone cavities. Very few wells in the region adjacent to SEDA utilize the limestone as a source of water, which may be due to the drilling depths required to intercept this water. Drilling depths of 600 to 700 feet are required to obtain water from the limestone.

2.3 SITE-SPECIFIC GEOLOGY

The site geology is characterized by gray Devonian shale with a thin weathered zone where it contacts the overlying mantle of Pleistocene glacial till. This stratigraphy is consistent over the entire site.

2.3.1 Competent and Weathered Shale

Gray competent shale was encountered between 6 and 14 feet below the land surface in all borings on the site and in the off-site surrounding areas. The bedrock topography slopes consistently to the west from an elevation of 720 feet in the eastern portion of the site to 614 feet MSL in the western portion of the site. Bedrock topographic gradients are steepest in the eastern portion of the site (as is the land surface topography).

A thin (1.5 to 12 feet thick) zone of gray weathered shale was encountered in all locations drilled on-site. This zone is characterized by fissile shale with a large amount of brown

FINAL EE/CA SENECA ASH LANDFILL

interstitial silt and clay. The thickness of the weathered shale varies throughout the site with the greatest thickness occurring approximately 260 feet west of the incinerator building and the least thick area occurring approximately 400 feet north of the incinerator building. A small weathered shale trough with a northeast-southeast oriented axis is located south of the incinerator building area and culminates at the thickest portion of the weathered shale near monitoring well PT-20 (Figure 2-3). The transition from the competent weathered shale is sharp based on drilling characteristics. No outcrops of weathered or competent shale are exposed on the site.

232 Glacial Till

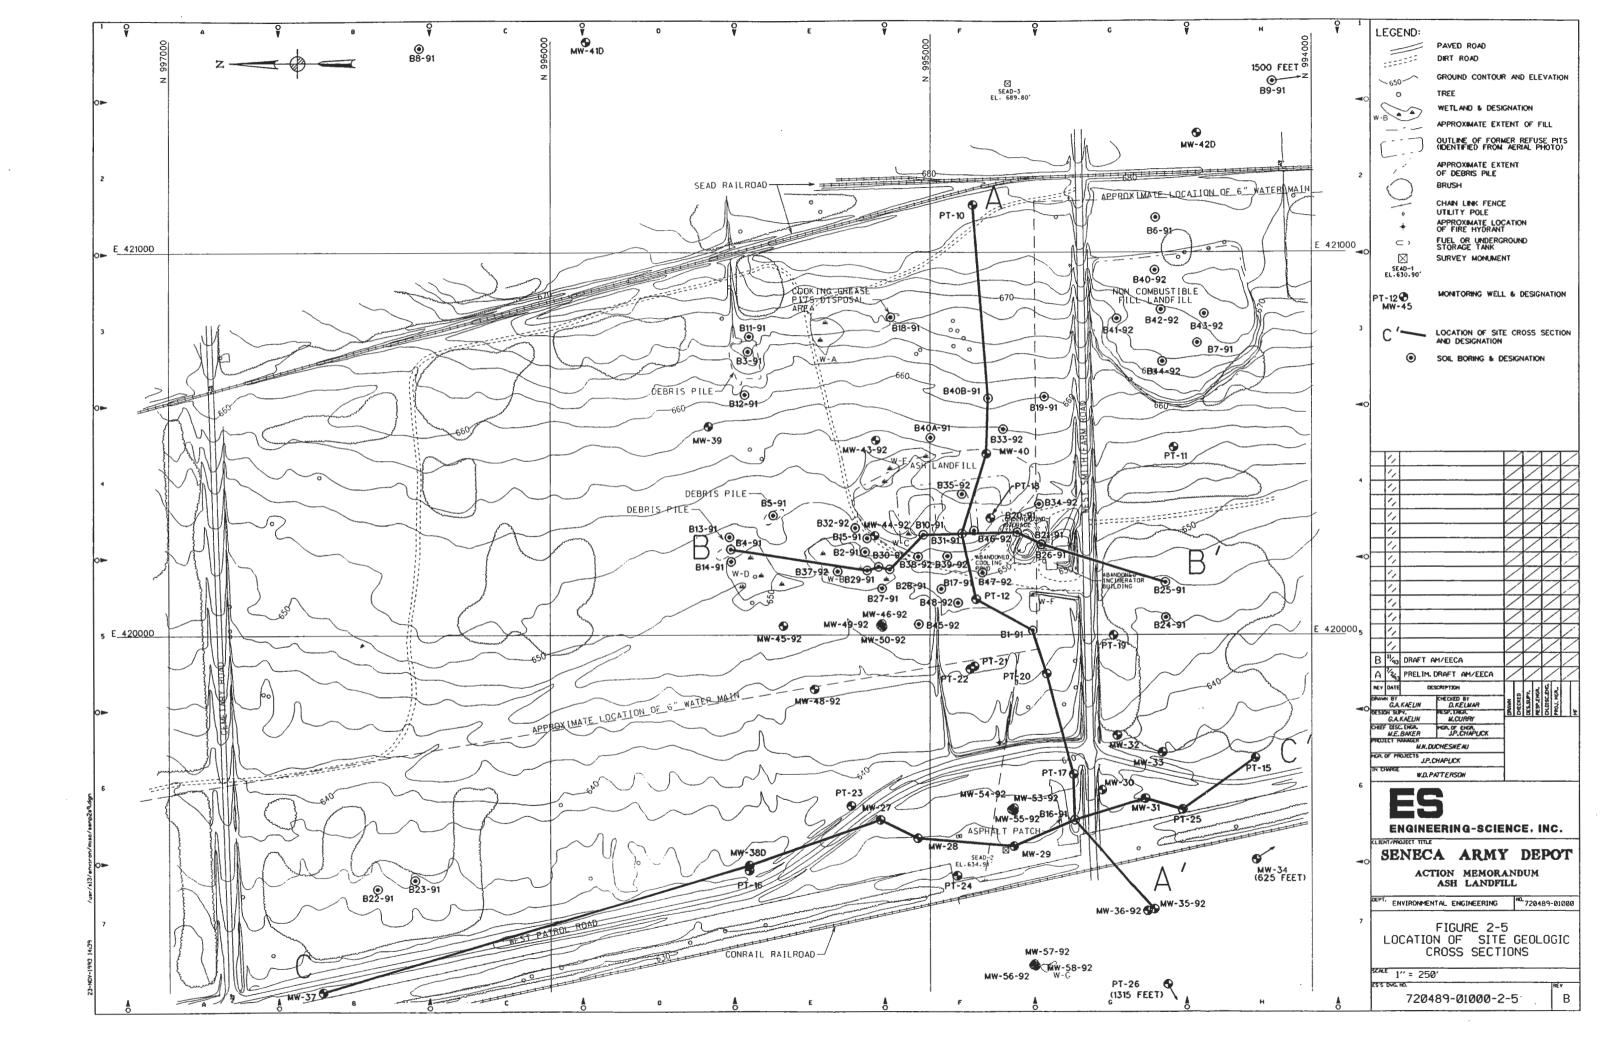

A 2 to 11 foot thick mantle of dense glacial till covers the shale on-site. The till is generally characterized by brown to gray-brown silt, clay, and fine sand with few fine to coarse gravel-sized inclusions of weathered shale. Larger diameter weathered shale clasts (as large as 6 inches in diameter) are more prevalent in basal portions of the till and are probably ripped-up clasts removed by the once active glacier. The general Unified Soil Classification System description of the till on-site is as follows: clay-silt, brown; slightly plastic, small percentage of fine to medium sand, small percentage of fine to coarse gravel-sized gray shale clasts, dense, and mostly dry in place, till (ML) - USCS Designation.

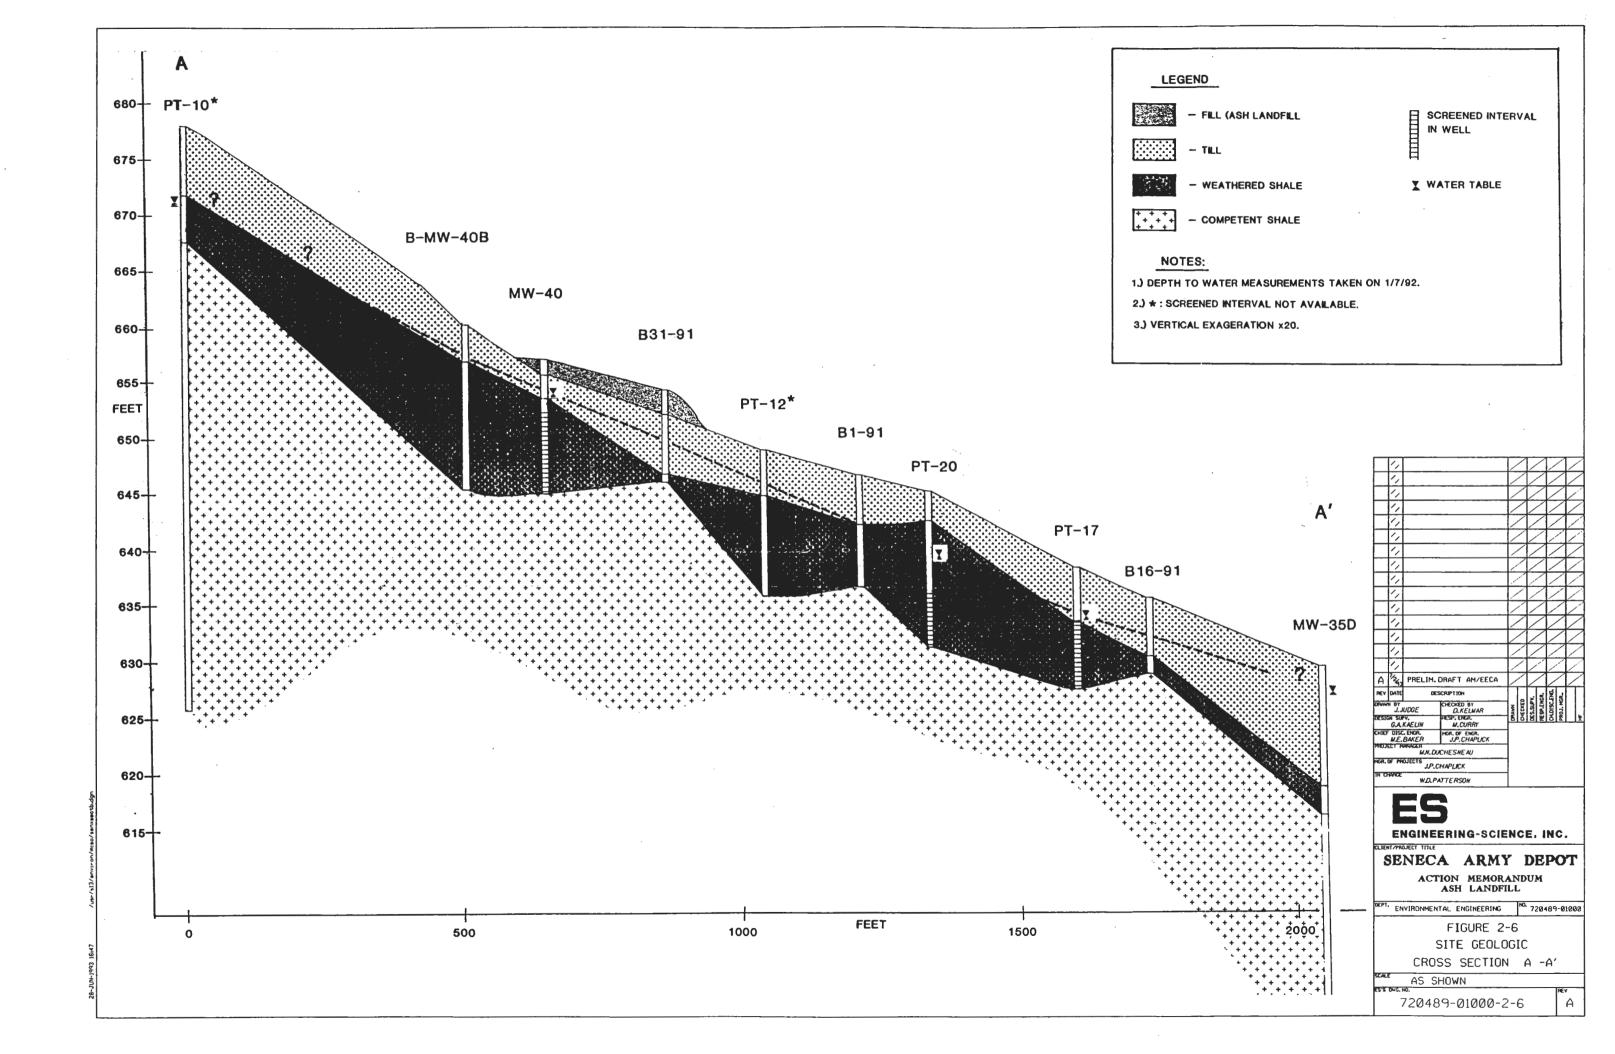

Darian silt-loam soils, 0 to 18 inches thick, are developed over the till on-site; however, in some locations the till is exposed at the surface. The surficial soils are somewhat poorly drained and have a silt clay loam and clay subsoil. The topographic relief associated with these soils is 3 to 8%.

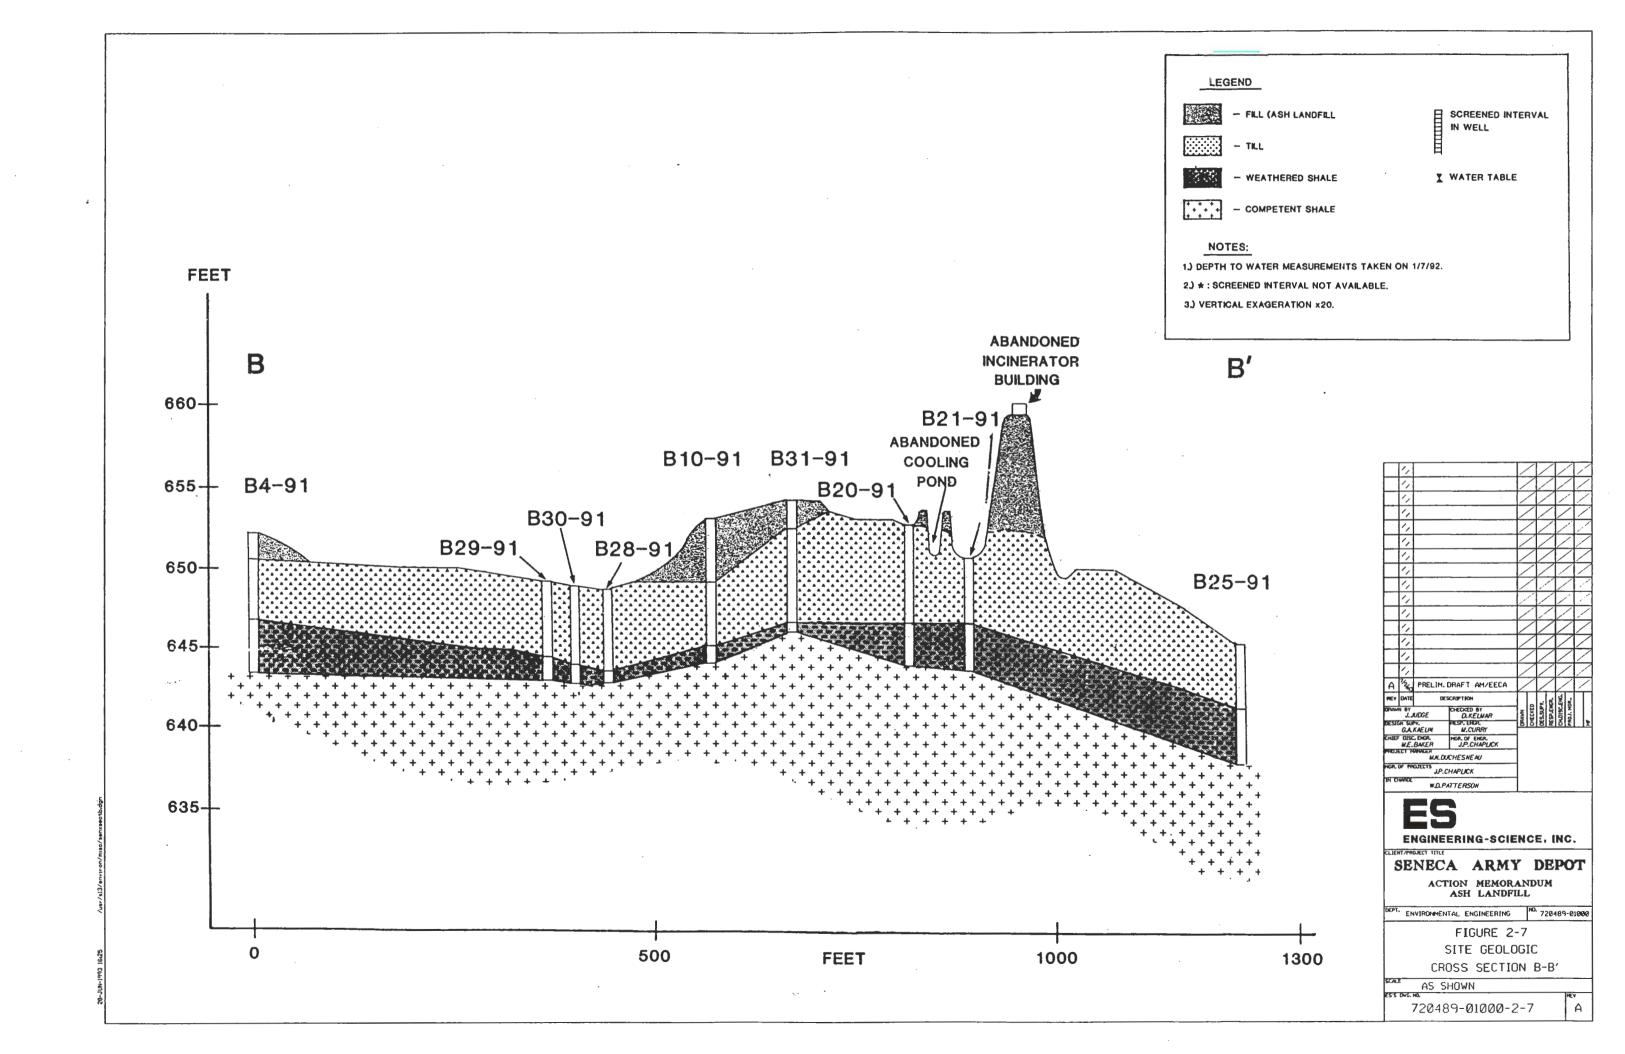

2.3.3 **Cross-Sections**

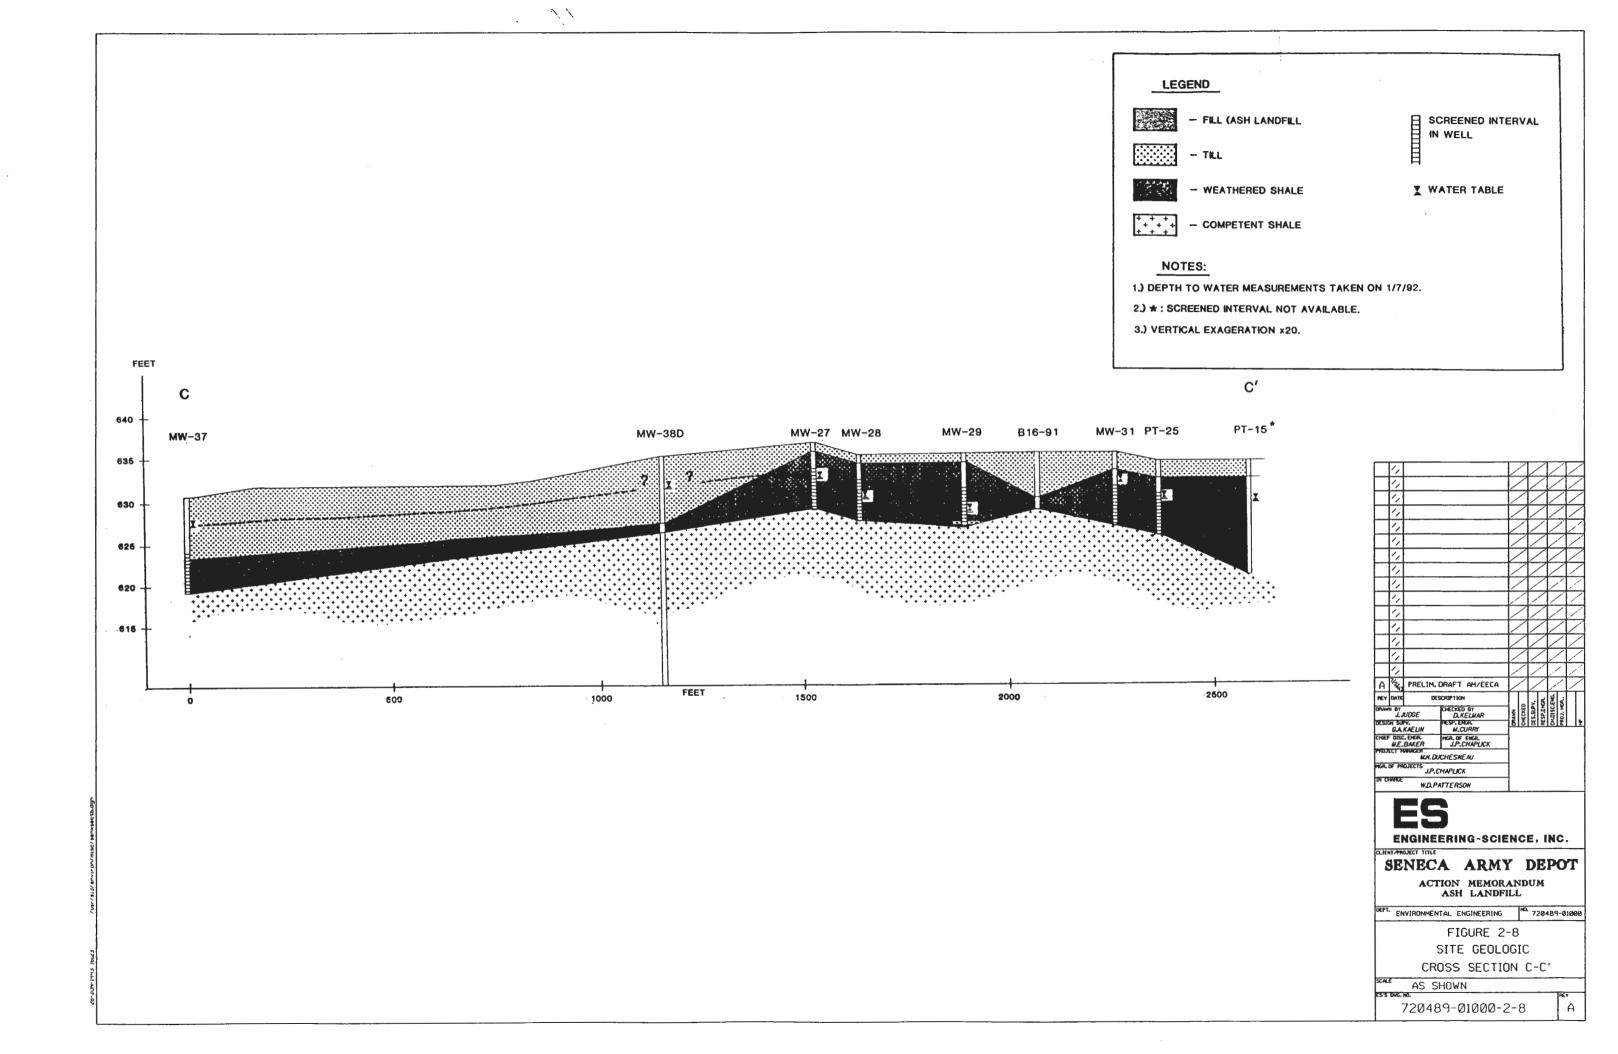

Three site-wide geologic cross-sections were constructed, along with two cross-sections devoted exclusively to the bend in the road area. The locations of the site-wide cross-sections are shown in Figure 2-5. East-west Cross sections A-A' and north-south Cross-sections B-B' and C-C' show the consistent till-weathered shale-competent shale stratigraphy beneath the site based on data from borings and monitoring wells (Figure 2-6 through 2-8). The scale of the sections did not permit identification of the soil horizon. Cross-section A-A' illustrates the variable thickness of the weathered shale and the relatively uniform thickness of the till, which

Page 2-9 May, 1994

appears to thicken in the western portion of the site. The actual ash landfill containing incinerator ash, and up to 4 feet-thick, is shown on Sections A-A' and B-B'.

The locations of the bend in the road cross-sections are shown on Figure 2-9. These sections (Figures 2-10 and 2-11) cut north-south, E-E and northeast-southwest, D-D, across the areas of interest. The depth to bedrock is approximately 8 feet in the bend in the road area and identify the extent of the fill from the Ash Landfill. The material to be remediated consists primarily of glacial till and weathered shale, with small quantities of fill in the former ash landfill.

2.3.4 Filled Areas

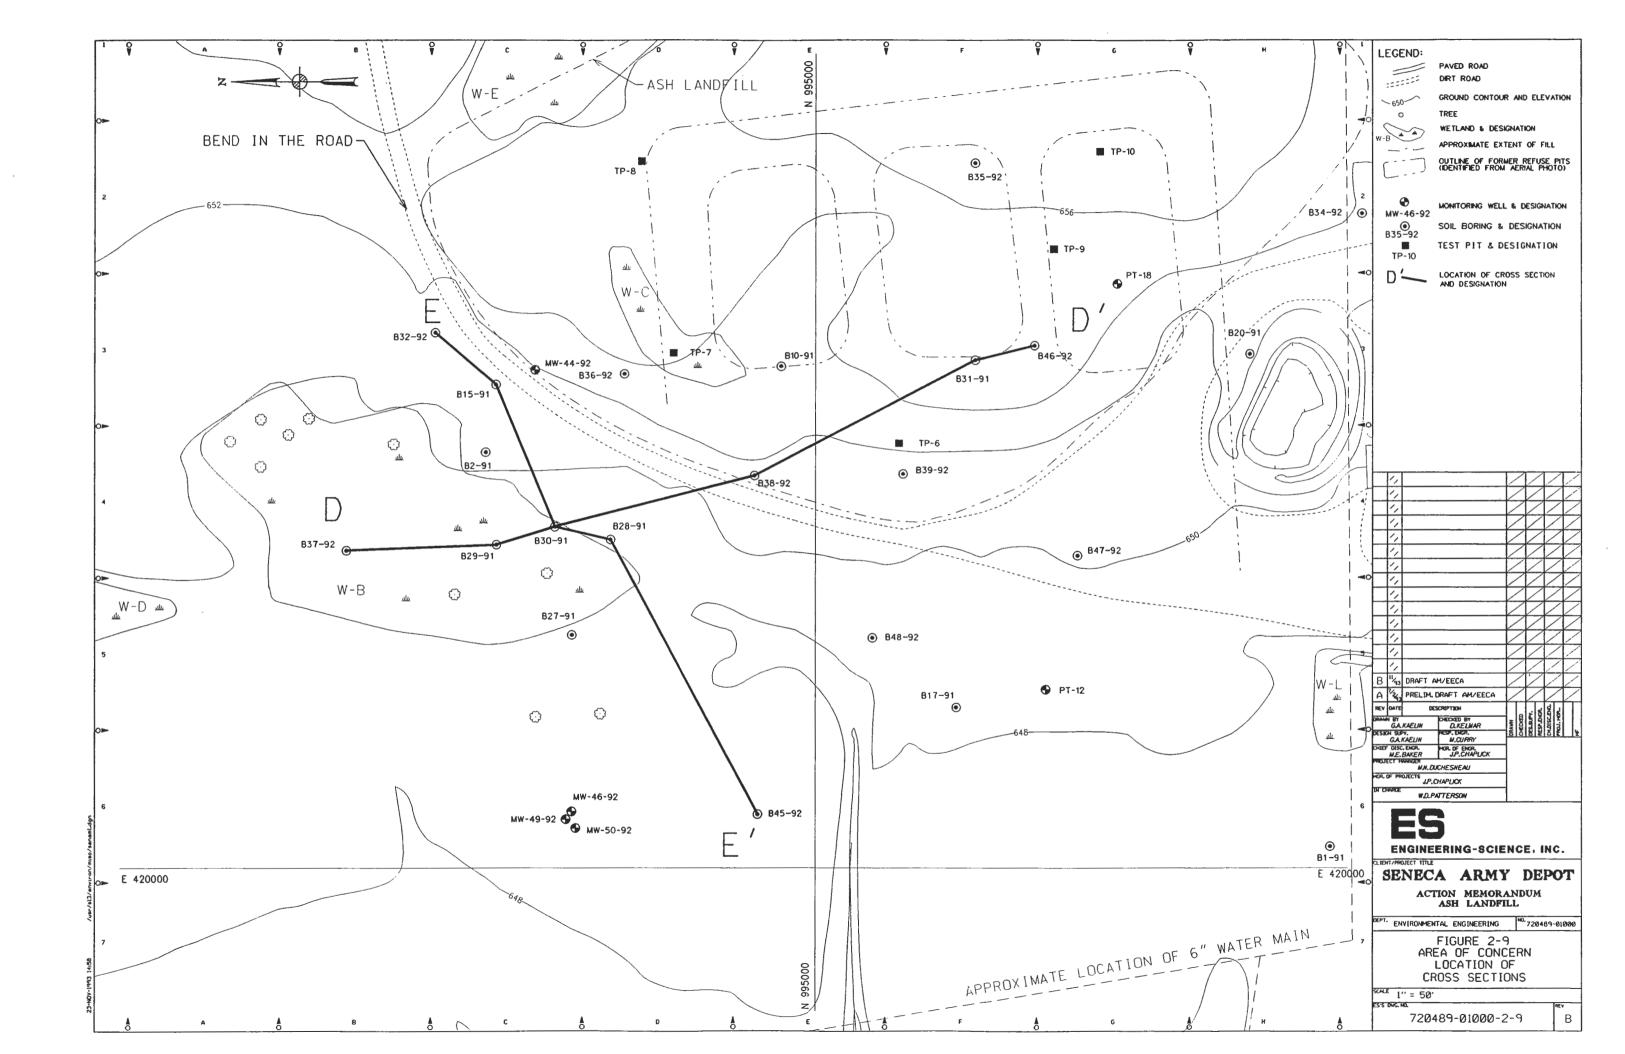

Several filled areas exist on the site. These include the former Ash Landfill, numerous debris piles and the Non-Combustible Fill Landfill. The approximately 600 by 300 foot Ash Landfill is presented in cross-section on Figure 2-6. This ash fill is defined by the slightly higher elevation in this area. The three debris piles north and northeast of the Ash Landfill are at slightly higher elevations (1 to 2 feet) relative to the surrounding areas; this is especially evident at the easternmost debris pile. The Non-Combustible Fill Landfill, located across West Smith Farm Road, is a wedge of fill that originates south of boring B6-91 and thickens to the west to a point approximately 150 feet beyond boring B7-91. It is defined by the topographic expression of the fill which has a total relief of about 14 feet at the western toe. This fill is underlain by thin horizons of till and weathered shale, below which is competent shale.

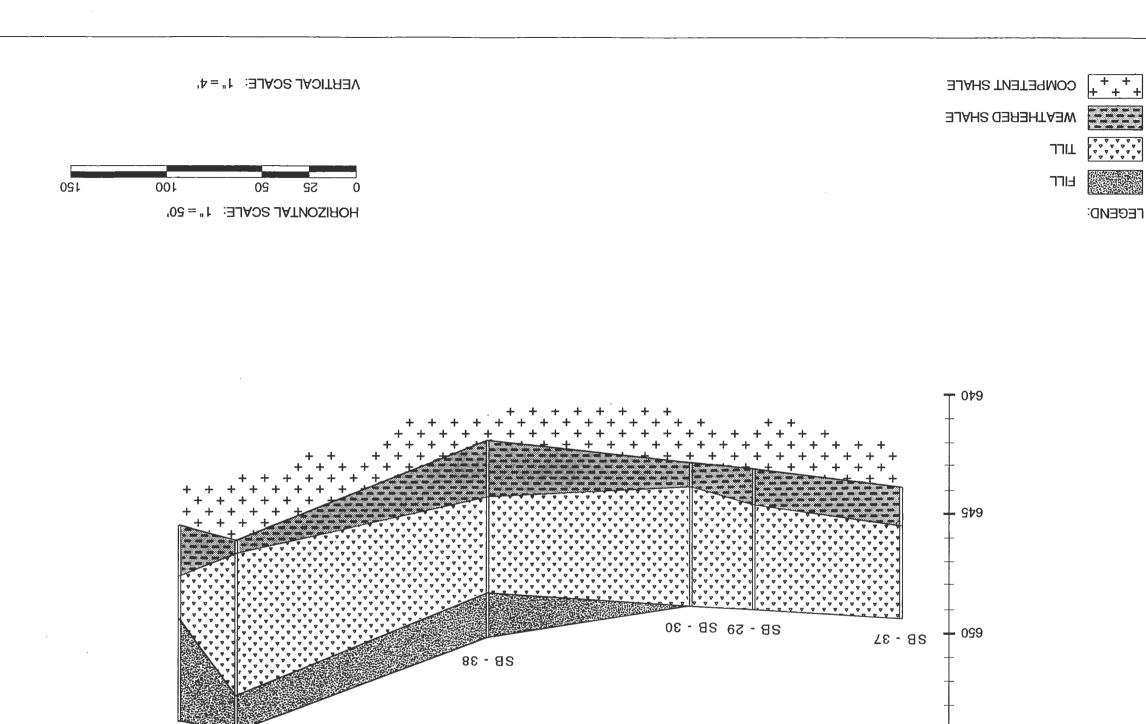

2.4 SITE-SPECIFIC HYDROGEOLOGY

2.4.1 Introduction

The hydrogeologic properties of the site were characterized during the RI. This section presents these results and addresses topics such as saturated thickness, horizontal and vertical direction of groundwater flow, groundwater gradients, hydraulic conductivities of shallow and deep aguifers, and groundwater velocity on-site.

2.4.2 Saturated Thickness of Shallow Aquifer

Representative saturated thicknesses in all on-site monitoring wells are indicated in Table 2-1. The average saturated thickness in the shallow aguifer is 8.7 feet based on January 7, 1992 depth to water measurements. Generally, saturated thicknesses are greatest in the eastern and southwestern portions of the site. The saturated thickness in wells PT-12 and PT-18, the two wells located the closest to the bend in the road area ranged from 3.9 to 8.2 feet for PT-12 and 2.5 to 5.9 feet for PT-18.

Historically, saturated thickness has fluctuated widely on the site based on depth to water measurements made during past groundwater sampling events (Table 2-1). A comparison of saturated thicknesses from September 1990 and January 1992 yields an average difference of 4.76 feet. The September 1990 data indicates an absence of a shallow aguifer in the area of MW-29 and aquifer thicknesses of less than 2 feet in many locations on the site.

2.4.3 Groundwater Flow Directions - Shallow Aguifer

A groundwater topography map was constructed based on depth to water measurements (Figure 2-12). The map indicates that the general direction of groundwater flow in the shallow aquifer is to the west toward Seneca Lake roughly mimicking surface topography. Shallow aquifer elevations are approximately 655 feet mgl in the eastern portion of the site and drop to a low of 630 feet mgl in the western portion of the site.

The groundwater gradient between wells PT-18 and PT-17 was calculated to be 0.021 feet per foot based on depth to water measurements made on January 7, 1992. Groundwater flow contours indicate that there is a consistent gradient over the entire site.

2.4.4 Groundwater Flow Directions - Deep Aquifer

Groundwater elevations in deep bedrock wells are higher in the eastern portion of the site (between approximately 680 and 686 feet mgl) than they are in the western portion of the site (between approximately 630 and 634 feet mgl) suggesting that a westerly direction of flow in the deep aquifer is likely.

Page 2-18 May, 1994

Average	3.10	8.74	4.76

Note

^{*} Depth to water measurements made by National Environmental Testing during a September 1990 sampling event

While these data suggest a westerly direction of groundwater flow, the exact size and orientation of fractures in the shale on the site are uncertain and may significantly influence the flow direction. Mazola (1951) recognized two distinct sets of joints in the area. The main set, termed dip joints, appears to be in the form of two conjugate shear planes that intersect to form acute angles ranging from 10° to 30°. The mean direction of the dip joints ranges from North 15° to 30° East to North 30° to 45° West. Strike joints at right angles to the dip joints trend from North 50° East to North 70° East and are spaced from 1 inch to 4 feet apart. The dip of the joint planes ranges from 46° to nearly vertical. In addition, most of the joints in the beds of the shale are filled with clay or fine silt which may inhibit groundwater flow.

2.4.5 <u>Vertical Connection Between Shallow and Deep Aquifers</u>

Vertical connection tests on paired wells PT-16 and MW-38D, and MW-36 and MW-35D indicate that there is a measurable drawdown in the shallow wells screened in the till and weathered shale when water is purged from their respective paired deep wells screened in competent shale.

Water level measurements from three different dates indicate that there is a downward vertical gradient in the area of PT-16 and MW-38D well cluster where an average head difference of +0.43 feet was calculated. This suggests that downward component of groundwater flow into the deep aquifer exists. Topographically and hydrologically downgradient from this location, a weaker upward movement of groundwater was measured in the area of the MW-36 and MW-35D well cluster where an average head difference of -0.13 feet was calculated.

Based on this data, downward movement of groundwater occurs from the shallow till/weathered shale aquifer into the upper portions of the competent shale aquifer; however, in deeper portions of the competent shale aquifer groundwater movement is upward, possibly driven by the topographic highs between Seneca and Cayuga Lakes. It is likely that the size and distribution of fractures ultimately controls the relative movement of groundwater seepage in this aquifer. There is a 51 foot difference in hydraulic head in the competent shale aquifer between eastern and western portions of the site, based on an average elevation between the two deep wells in each area (MW-38D and MW-35D, and MW-4D and MW-42D) as measured on January 7, 1992. The large differences in piezometric head suggests that movement in the shale aquifier is to the west.

2.4.6 Hydraulic Conductivities

Hydraulic conductivities were determined for both the shallow and deep aquifers at the Ash Landfill site (Table 2-2). Hydraulic conductivities for wells screened in the shallow till/weathered shale aguifer were determined using the method of Bouwer and Rice (1976). Average hydraulic conductivity values for the shallow aguifer range from 6.6 x 10⁻⁶ cm/sec to 3.0 x 10⁻⁴ cm/sec. Average hydraulic conductivity values for the deep aguifer range from 9.0 x 10⁻⁸ to 1.7 x 10⁻⁴. The average hydraulic conductivities for the shallow and deep aguifers are 1.4×10^{-4} and 4.0×10^{-6} cm/sec, respectively (Table 2-2).

By comparison, published hydraulic conductivity values for till or representatively similar materials include the following: 1) 0.49 m/day (5.67 x 10⁻⁴ cm/sec) for a repacked predominantly sandy till (Todd, 1976), and 2) from 10⁻² to 10⁻³ m/day (10⁻⁵ to 10⁻⁶ cm/sec) for representative materials of silt, sand, and mixtures of sand, silt, and clay (Todd, 1976).

2.4.7 Velocity of Groundwater

In accordance with, Darcy's Law, the average linear velocity of groundwater in the shallow till/weathered shale aquifer was estimated from the average site hydraulic conductivity, effective porosity and the on-site groundwater gradient. These values ranged from an average linear velocity of 0.11 feet/day or 38.9 feet/year for a porosity of 11% and 0.047 feet/day or 17.1 feet/year for a porosity of 25%.

2.5 AREA METEOROLOGY

Table 2-3 summarizes climatological data for the SEDA area. The nearest source of climatological data is the Aurora Research Farm located approximately 10 miles east of the site which provided precipitation and temperature measurements. The remainder of the data reported in Table 2-3 has been taken from isopleth drawings from the literature, or from data collected at the Syracuse Airport, New York, 40 miles northeast of the SEDA. Meteorological data collected from 1965 to 1974 at Hancock International Airport in Syracuse, New York, were used in preparation of the wind rose. The airport is located approximately 60 miles northeast of SEDA, and is representative of wind patterns at SEDA. The wind rose is presented in Figure 2-13.

³Climate Atlas of the United States. U.S. Department of Commerce, 1983.

Climate of New York Climatography of the United States No. 60. National Oceanic and Atmospheric Administration, June 1982. Data for Syracuse, NY.

A cool climate exists at SEDA with temperatures ranging from an average of 23°F in January to 69°F in July. Marked temperature differences are found between daytime highs and nighttime lows during the summer and portions of the transitional seasons. Precipitation is well-distributed, averaging approximately 3 inches per month. This precipitation is derived principally from cyclonic storms which pass from the interior of the county through the St. Lawrence Valley. Lakes Seneca, Cayuga and Ontario provide a significant amount of the winter precipitation and moderate the local climate. The annual average snowfall is approximately 100 inches. Wind velocities are moderate, but during the winter months there are numerous days with sufficient winds to cause blowing and drifting snow. The most frequently occurring wind directions are westerly and west-southwesterly.

As Table 2-3 shows, temperature tends to be highest from June through September. Precipitation and relative humidity tend to be rather high throughout the year. The months with the most amount of sunshine are June through September. Mixing heights tend to be lowest in the summer and during the morning hours. Wind speeds also tend to be lower during the morning, which suggests that dispersion will often be reduced at those times, particularly during the summer. No episode-days are expected to occur with low mixing heights (less than 500 m) and light wind speeds (less than or equal to 2 m/s).

Daily precipitation data measured at the Aurora Research Farm in Aurora, New York (approximately 10 miles east of the site) for the period (1957-1991) were obtained from the Northeast Regional Climate Center at Cornell University. The maximum 24-hour precipitation measured at this station during this period was 3.91 inches on September 26, 1975. Values of 35 inches mean annual pan evaporation and 28 inches for annual lake evaporation are shown in Table 2-3. An independent value of 27 inches for mean annual evaporation from open water surfaces was estimated from an isopleth presented in "Water Atlas of the United States" (Water Information Center, 1973).

Information on the frequency of inversion episodes for a number of National Weather Service stations is summarized in "MixingHeights, Wind Speeds, and Potential for Urban Air Pollution Throughout the Contiguous United States" (George C. Holzworth, US EPA, 1972). The closest stations for which inversion information is available are in Albany, New York, and Buffalo, New York. The Buffalo station is nearer to SEDA but almost certainly exhibits influences from Lake Erie. These influences would not be expected to be as noticeable at SEDA.

FINAL EE/CA SENECA ASH LANDFILL

SEDA is located in the Genesse-Finger Lakes Air Quality Control Region (AQCR). The AOCR is designated as non-attainment for ozone and attainment or unclassified for all other criteria pollutants. Data for the existing air quality in the area which surrounds the SEDA, cannot be obtained since the nearest state air quality stations are 40 to 50 miles away from the army depot, (Rochester of Monroe County or Syracuse of Onondaga County), and is not representative of the conditions at SEDA. A review of the data for Rochester, which is in the same AOCR as the SEDA, indicates that all monitored pollutants (sulfur dioxide, particulates, carbon monoxide, lead, and ozone) are below state and federal limits, with the exception of ozone. In 1987, the maximum ozone concentration observed in Rochester was 0.127 ppm; however, this value is not representative of the SEDA area which is a more rural environment.

CONTAMINATION ASSESSMENT 2.6

The results of the investigation activities are summarized below. These activities include both screening (such as soil gas surveys) and conformational soil sampling. The primary purpose of the screening activities was to provide information to be used in locating the conformational soil borings. Confirmation soil sampling was used to accurately determine the extent of the impacted soil. This discussion focuses primarily on the bend in the road area at the Ash Landfill, which is considered the primary source of groundwater contamination. discussion of the RI activities at the site can be found in the RI report (ES, 1993). Complete data tables for the RI including the eight (8) confirmatory soil borings are in Appendix B of the Action Memorandum.

2.6.1 Soil Gas

Three separate soil gas investigations have been carried out at the SEDA Ash Landfill. The first was conducted by Target Environmental, Inc. (Target) under the supervision of ICF as part of the Phase I RI (USATHAMA, 1989). In their investigation, Target collected soil gas samples from a grid network over the entire Ash Landfill site to identify potential hot spots. Several areas with elevated soil gas concentrations were identified, including two areas near the "bend in the road" area. One of these areas southeast of the "bend in the road", contained a soil gas concentration of 11,000 μ g/L (1880 ppmv as TCE). This was the highest value obtained during the target survey and was an order of magnitude higher than the next highest value of 655 μ g/L (112 ppmv as TCE) which was detected in the "bend in the road" area.

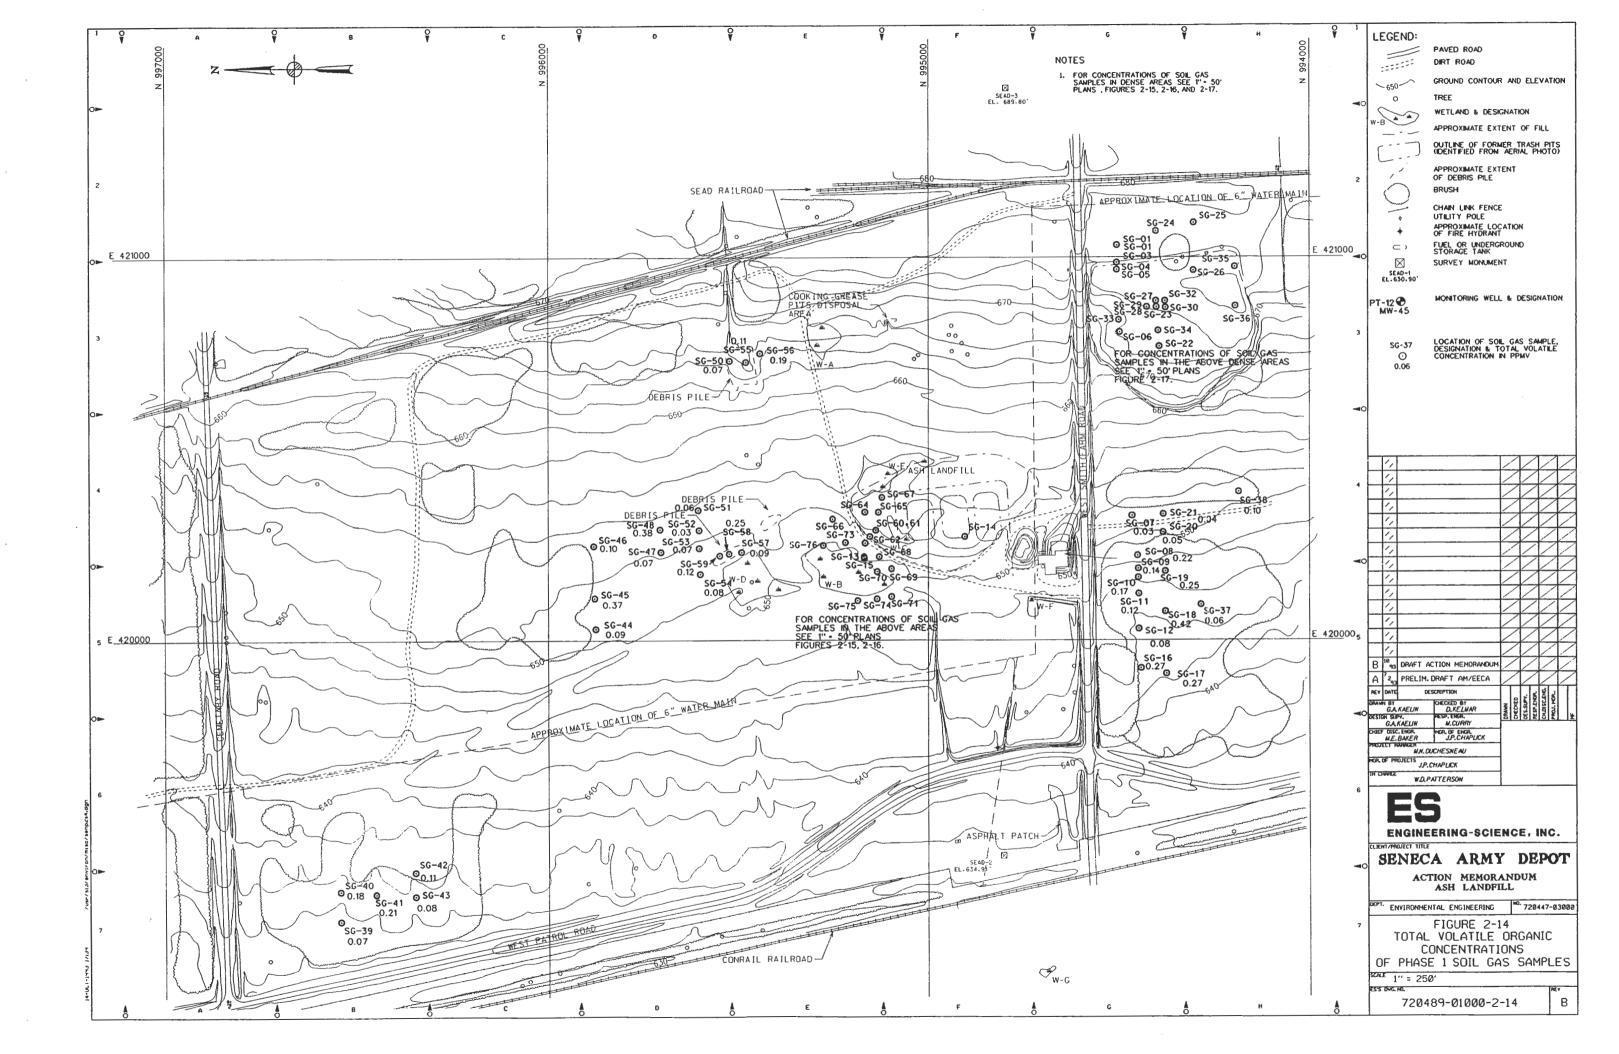

Page 2-27 May, 1994

As a follow up to the Target Survey, C.T. Main (MAIN) performed a soil gas survey in November, 1991 to evaluate the potential for VOC's at geophysical anomalies around the Ash Landfill and at the Non-Combustible Fill Landfill. Additionally, the MAIN survey confirmed the areas of concern identified by the Target Survey. This investigation refined the results of the Target Survey by collecting soil gas samples at closer spacings. The results of MAIN's investigation correlated well with the results of the Target investigation.

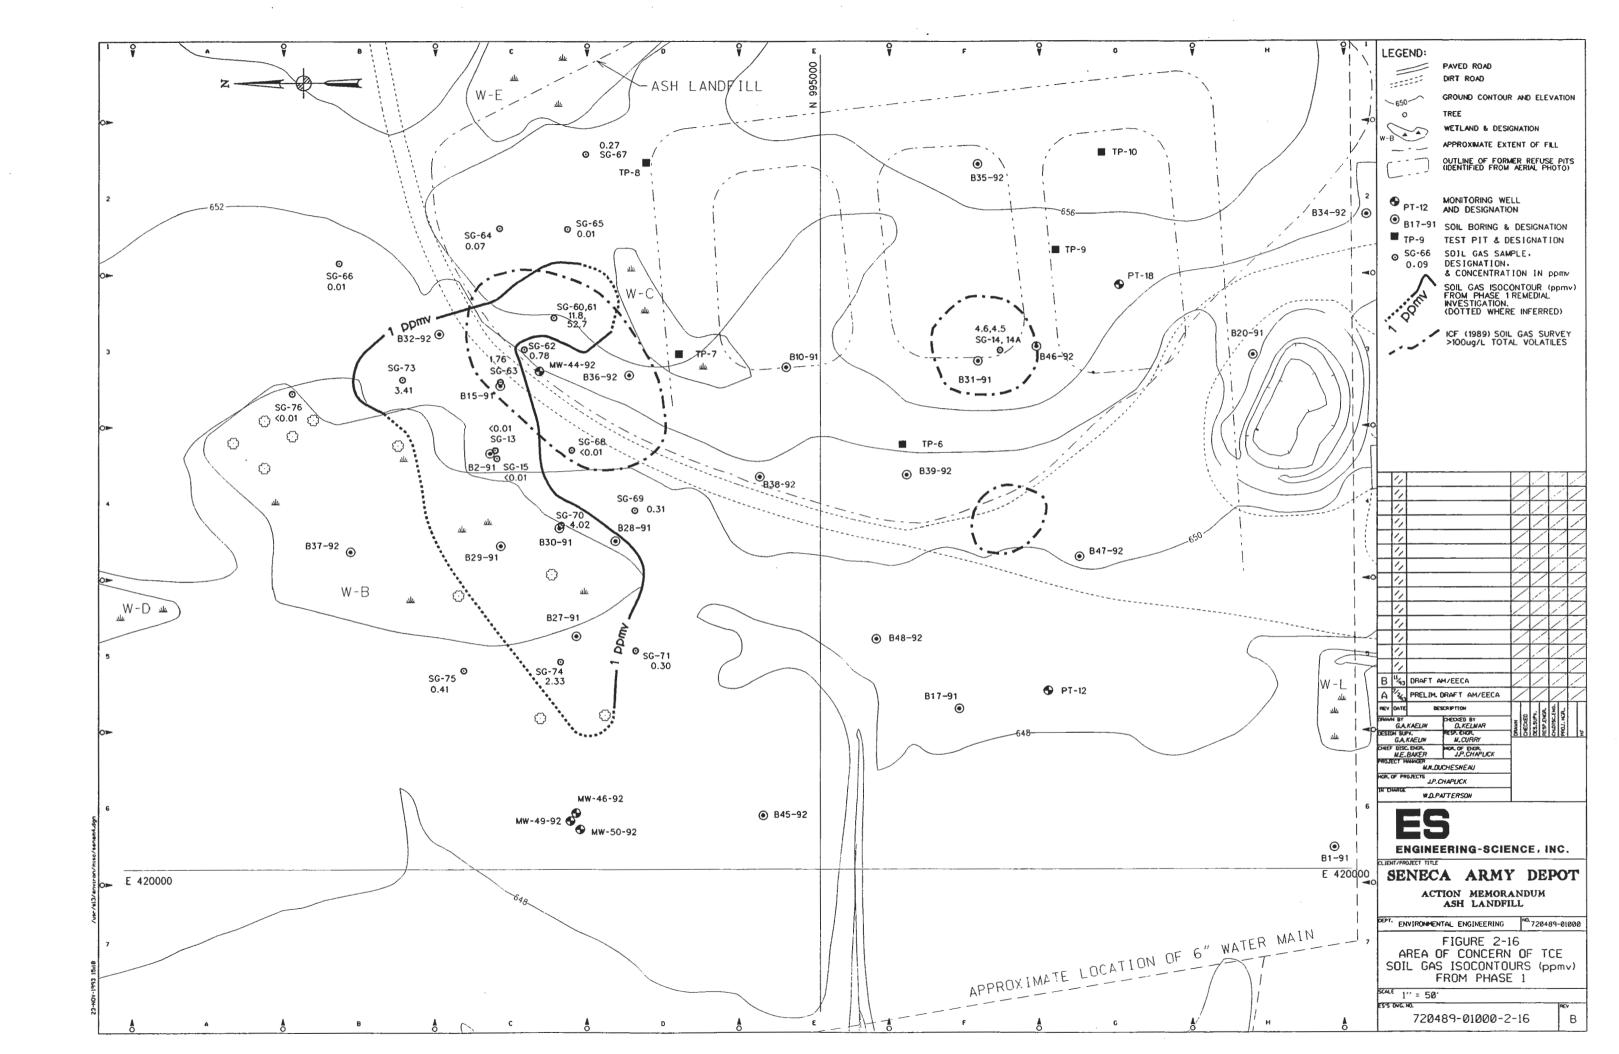

Near the "bend in the road", the MAIN survey determined the total volatile organics in soil gas were as high as 86.6 ppmv (655 ug/L) which compared well to the highest Target soil gas value of 112 ppmv. Experience has shown that soil contamination may be present at concentrations exceeding 1 ppmv. A 1 ppmv total volatile organics isocontour encompasses an area approximately 250 feet by 175 feet (Figure 2-14). Trichloroethane (TCE) concentrations in soil gas are also provided on Figure 2-15. This soil gas survey identified a possible source area for volatile organic compounds in soil (i.e., an area encompassed by 1 ppmv isocontour).

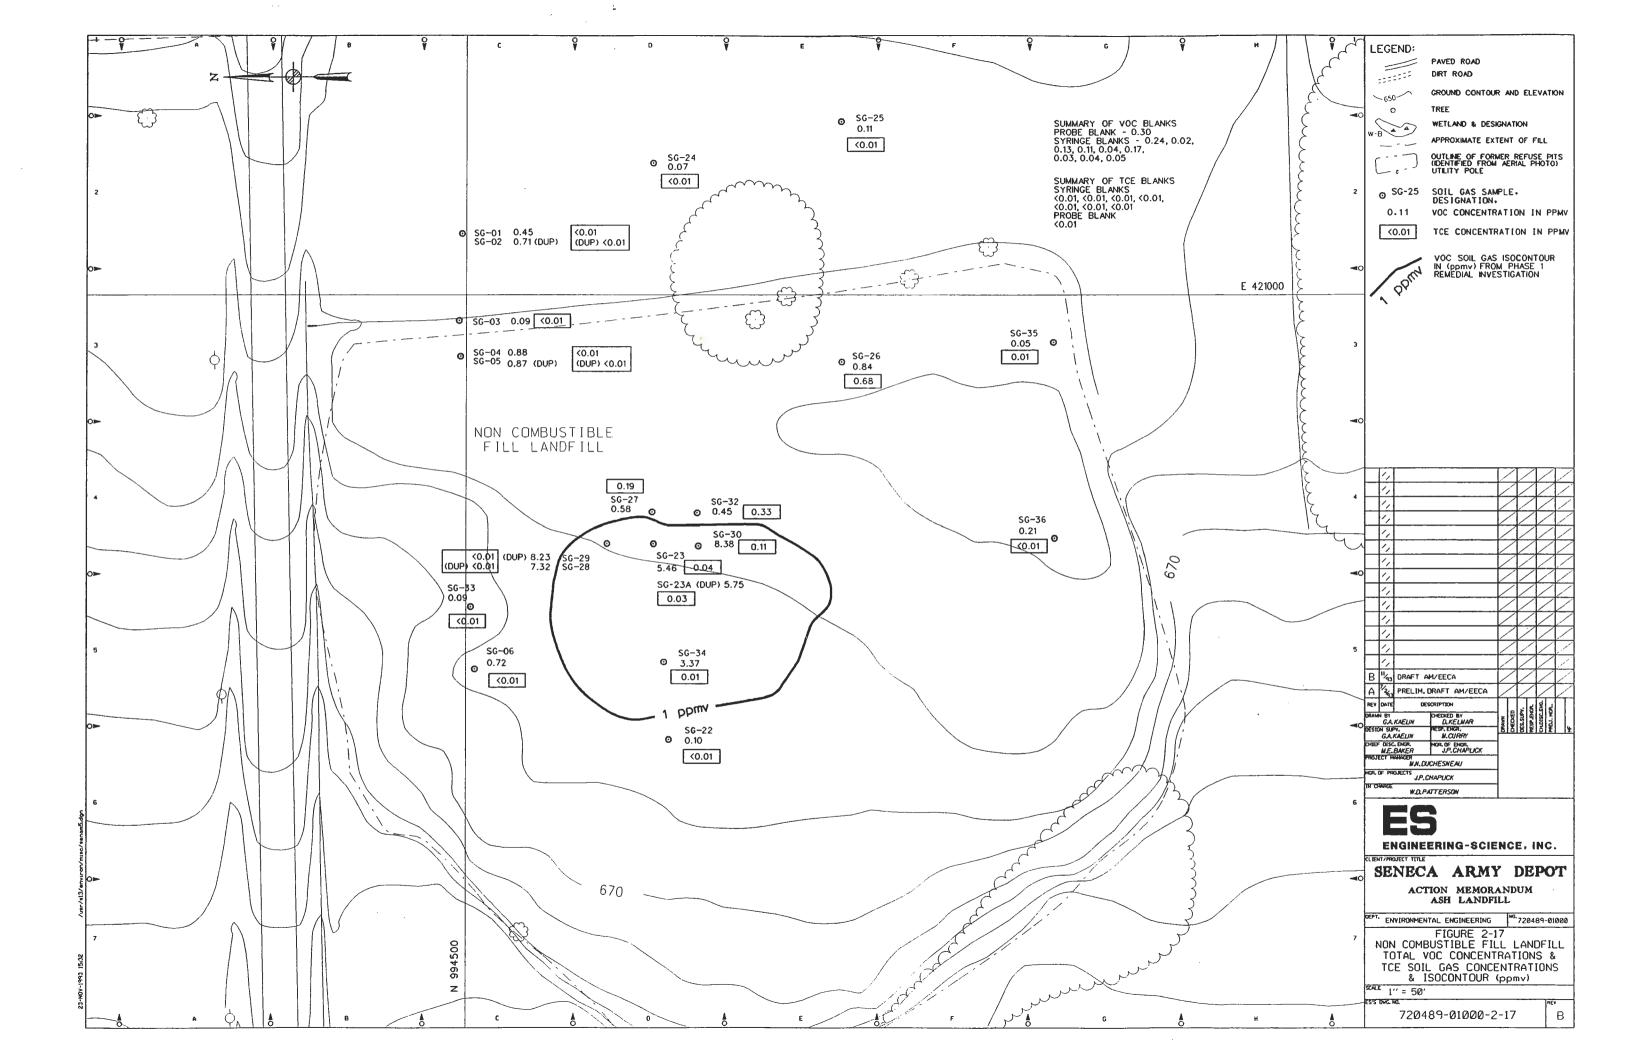

Areas identified in the Target (1989) soil gas survey with soil gas concentrations of over 100 μ g/L 17.1 ppmv as TCE are shown in expanded scale on Figure 2-16 and 2-17. In the southeasternmost location, a total volatile organics concentration of approximately 11,000 μ g/L (approximately 1880 ppmv) was detected. This value was localized in one spot. Soil gas concentrations decreased substantially a small distance from this area. For comparison with the MAIN survey, a soil sample from this approximate location was collected during MAIN's soil gas survey and a concentration of approximately 50 ppmv was determined. Differences in concentration are not unexpected using soil gas techniques given the time between sampling events and the error associated with locating the two collection points. Soil gas concentrations determined by MAIN are generally higher near the bend in the road (up to 86.6 ppmv) than was previously identified by Target. The conclusions from both surveys are consistent and suggest a source of the observed groundwater impacts.

A third soil gas survey was performed in April 1993 to eliminate uncertainties associated with the soil gas contours and provide more resolution for the two areas identified earlier. This soil gas investigation was carried out by ES (formerly MAIN). The purpose of this investigation was to fully delineate the two hot spots identified near the bend in the road for the purpose of determining the area to be addressed by this removal action. The original plan was to conduct the investigation using the same methodology as that of the MAIN investigation; however, due to heavy precipitation and snowbelt, the soils at the site were saturated. This eliminated the use of soil gas since no gas was available, necessitating a change

in the work plan. Using 2-inch-diameter split spoons, driven to a depth of 4 feet, a soil sample was collected and placed in a 40-ml VOA vial with a Teflon septum. Headspace samples were then collected from the vial and analyzed in a manner similar to the analysis of the soil gas using a Photovac model 10S50 portable GC.

The results of this investigation are summarized in Table 2-4 and Figure 2-18. The results were tabulated in units of Volt-seconds (Vs), which are the units of the integrator output.

From this survey, areas of elevated soil gas were fully delineated and used as the basis for follow-up soil borings. Eight (8) confirmations soil borings were collected just outside the areas of elevated soil gas concentrations in order to confirm the extent of soil impacts. Previous soil sampling within the areas of elevated soil gas concentrations had identified the presence of chlorinated volatile organics in soil. Only one sample collected from these eight borings detected the presence of TCE, DCE, or vinyl chloride in excess of the NYSDEC TAGM soil cleanup criteria. The results of these soil borings are detailed below. Following the soil headspace survey and the confirmatory soil sampling, two areas of soil contamination were delineated, comprising approximately 38,000 and 17,000 square feet, respectively. These two (2) areas, are the focus of this removal action.

2.6.2 <u>Soil</u>

2.6.2.1 Volatile Organic Compounds

Volatile organic compounds are the primary analytes of concern identified in most of the soil samples collected during the boring program (Figures 2-19 through 2-23). The volatile organics include vinylchloride TCE, DCE (total), 1,2-dichloroethane (one occurrence). These results from the soil samples collected in the "bend in the road" area are summarized in Table 2-5.

The highest concentrations of volatile organic compounds found at the site were detected in samples from varying depths (2 to 8 feet) in the fill of the Ash Landfill and immediately northwest of this filled area, near the bend in the road. The highest concentration of volatile organic compounds (641,700 μ g/kg of mostly TCE) was found in the 2-4 foot sample in B15-91 (Figure 2-19). Generally, concentrations of total volatile organic compounds decrease in a westward direction between boring B15-91 and B45-91 (on the western side of wetland B).

SENECA ASH LANDFILL FINAL EE/CA

Two areas of soil contamination have been delineated at the "bend in the road" area. The northern area is approximately twice as large as the southern area. These two areas are separated by a small strip of uncontaminated soil. The highest concentrations of total volatiles from two borings in the central portion between the two contaminated areas (B10-91 and B38-92) were approximately 1600 and 350 μ g/kg at 6'-8' (Figure 2-22). The western portion of the Ash Landfill and areas near the "bend in the road" and wetland B are the primary source areas for volatile organic compounds in groundwater.

A comparison of VOCs (including 1,2-DCE and TCE) in selected soil samples from borings at areas of high soil gas are presented in Table 2-6. In most instances when VOCs are found in the soil gas they are also found in the soil, supporting the use of soil gas techniques to locate source area for volatile organic compounds.

As previously mentioned in Section 2.6.1, soil headspace was performed during Phase 2 to delineate the vertical extent of soil impacts. After the soil headspace survey was completed, eight soil borings were collected just outside the two areas identified by the soil headspace survey as the primary source of the volatile organic contamination. The locations of these eight (8) borings are shown on Figure 2-19, and the results are summarized in Table 2-5. These borings are: B32, B36, B37, B38, B45, B46, B47 and B48. Of the thirty-three (33) soil samples collected, only one (1) sample, B47 at the 4'-5.3'depth, exceeded only one NYSDEC TAGM value, for DCE.

2.6.2.2 Semivolatile Organic Compounds

Table 2-5 also provides a summary of only those semi-volatile compounds detected above the NYSDEC TAGM values. The list includes Polynuclear Aromatic Hydrocarbons (PAHs), phthalates, phenol and phenolic compounds. PAHs are commonly detected as Products of Incomplete Combustion (PICs) and are not unexpected from the residue of a municipal incinerator.

Semivolatile organics compounds were detected in 18 of the 23 in the vicinity of the bend in the road (Table 2-5). The highest total semi-volatile concentrations and widest variety of compounds were found in samples from B10-91, B31-91, B36-93 and B15-91 and B15-91 where the 0-2 foot samples from both locations contained 13,740, 1,820, 3,010 and 1,287 μ g/kg, respectively. The concentration of semi-volatile compounds, especially PAHs, decrease with increasing depth, suggesting little penetration following surface deposition.

Notes:

Soil gas locations are shown in parentheses beneath the concentration

Concentrations for soil analyses are mg/Kg

Concentrations for soil gas analyses are in ppmv

SENECA ASH LANDFILL FINAL EE/CA

Borings in the Ash Landfill and in the "bend in the road" area near wetland W-B generally contain semi-volatiles from the surface to the bottom of the boring, although the concentrations in this area are not as high as those from other areas of the site such as the debris pile and Non-Combustible Fill Landfill. Detectable concentrations of semi-volatiles from this area range between 83 ug/kg in boring B37-93 and 13,740 µg/kg in B10-91.

2.6.2.3 Pesticides/PCBs, and Herbicides

No Pesticides/PCBs or Herbicides were detected above NYSDEC TAGMs in the bend in the road area.

2.6.2.4 Metals and Cyanide

A summary of the results for the metals and cyanide is presented in Table 2-7. As would be expected for any soil, many of the Target Analyte List (TAL) metals were detected in every boring collected at the "bend in the road" area. Of the numerous metals detected, copper, lead, mercury and zinc are considered significant due to their toxilogical effects and the concentrations detected.

Low to moderate concentrations of copper were detected in the central portion of the Ash Landfill, near the "bend in the road" area, primarily at the 0 to 2 foot depth interval at borings B10 and B31. The maximum copper concentration observed was 105 mg/kg in boring B10. The NYSDEC TAGM value for copper is 25 mg/kg. The location of these borings is presented on Figure 2-19. The vertical extent of copper impacts is from 0 to 4 feet, although some slightly elevated concentrations above the TAGM value below a depth of 4 feet were detected in borings B-31, B-36 and B-38.

Low to moderate lead concentrations were detected in borings B-31, B-35 and B-46 at the center of the Ash Landfill (Figure 2-19) at the depth interval of 2 to 4 feet. The maximum concentration detected was 696 mg/kg in borings B31 at the 2 to 4 foot depth. Generally, concentrations of lead decrease to below the NYSDEC TAGM values with increasing depth at location which have samples above the TAGM value.

May, 1994 Page 2-53

FINAL EE/CA SENECA ASH LANDFILL

Zinc concentration were detected in the Ash Landfill at concentration above the NYSDEC TAGM value for the depth intervals of 0 to 2 feet, and from 2 to 4 feet. The maximum concentration of zinc was 6,290 mg/kg and was detected in boring B-35 at the 0 to 2 foot depth. At the 2 to 4 foot depth for this same boring the concentration of zinc was determined to be 4,210 mg/kg. For this site, the NYSDEC TAGM value for zinc is considered to be background which was determined to be 89 mg/kg. The Ash Landfill appears to be affected by elevated concentrations of zinc down to a depth of approximately 4. Below this depth, only B-31 contained zinc at elevated concentrations.

Concentrations of mercury were also detected in the Ash Landfill at boring locations B-10, B-17 and B-35, down to a depth of between 0 and 4 feet. The maximum mercury concentration was 0.76 mg/kg and was detected at boring B-35 the 2 to 4 foot depth interval. The NYSDEC TAGM value for mercury at this site is 0.1 mg/kg.

No cyanide concentrations were detected above the NYSDEC TAGM value in the area of concern.

The horizontal and vertical extent of these metals appears to be coincident with the Ash Landfill, Figure 2-19, and is likely associated with the former incinerator ash.

2.6.2.5 Total Recoverable Petroleum Hydrocarbons

The presence of other organic chemical constituents which are not part of the TCL list of analytes were reviewed and presented as Tentatively Identified Compounds (TIC)s in Appendix B. These analytes have been reviewed to determine the presence of petroleum hydrocarbons. Petroleum hydrocarbons are of interest since NYSDEC has established a value for clean-up of 10 mg/kg. The presence of these materials are described as tentative because standards were not prepared to quantitate the concentrations determined. Accordingly, the concentration values presented are only estimates and can be somewhat different than what would be determined by other, more traditional methods for determining petroleum hydrocarbons. Nonetheless, the largest concentration of TICs, which were identified as a series of high molecular weight alkane hydrocarbons, was detected at borings B-2, B-15, B-32 and B-36 and were determined throughout the soil column from 2 to 8 feet in depth.

Page 2-63 May, 1994

2.6.3 Groundwater

2.6.3.1 Volatile Organic Compounds

As with the soil samples, volatile organic compounds are the primary analytes of concern detected in the groundwater at the site. Volatile compounds were detected in nine (9) of the thirty monitoring wells sampled. The VOCs detected included TCE, 1,2-DCE (total), vinyl chloride, chloroform, 2-Butanone, xylene (total), methylene chloride, and acetone. The latter two compounds are believed to be laboratory contaminants. TCE and 1,2-DCE are the volatile organics which have been detected in many of the wells and are of concern.

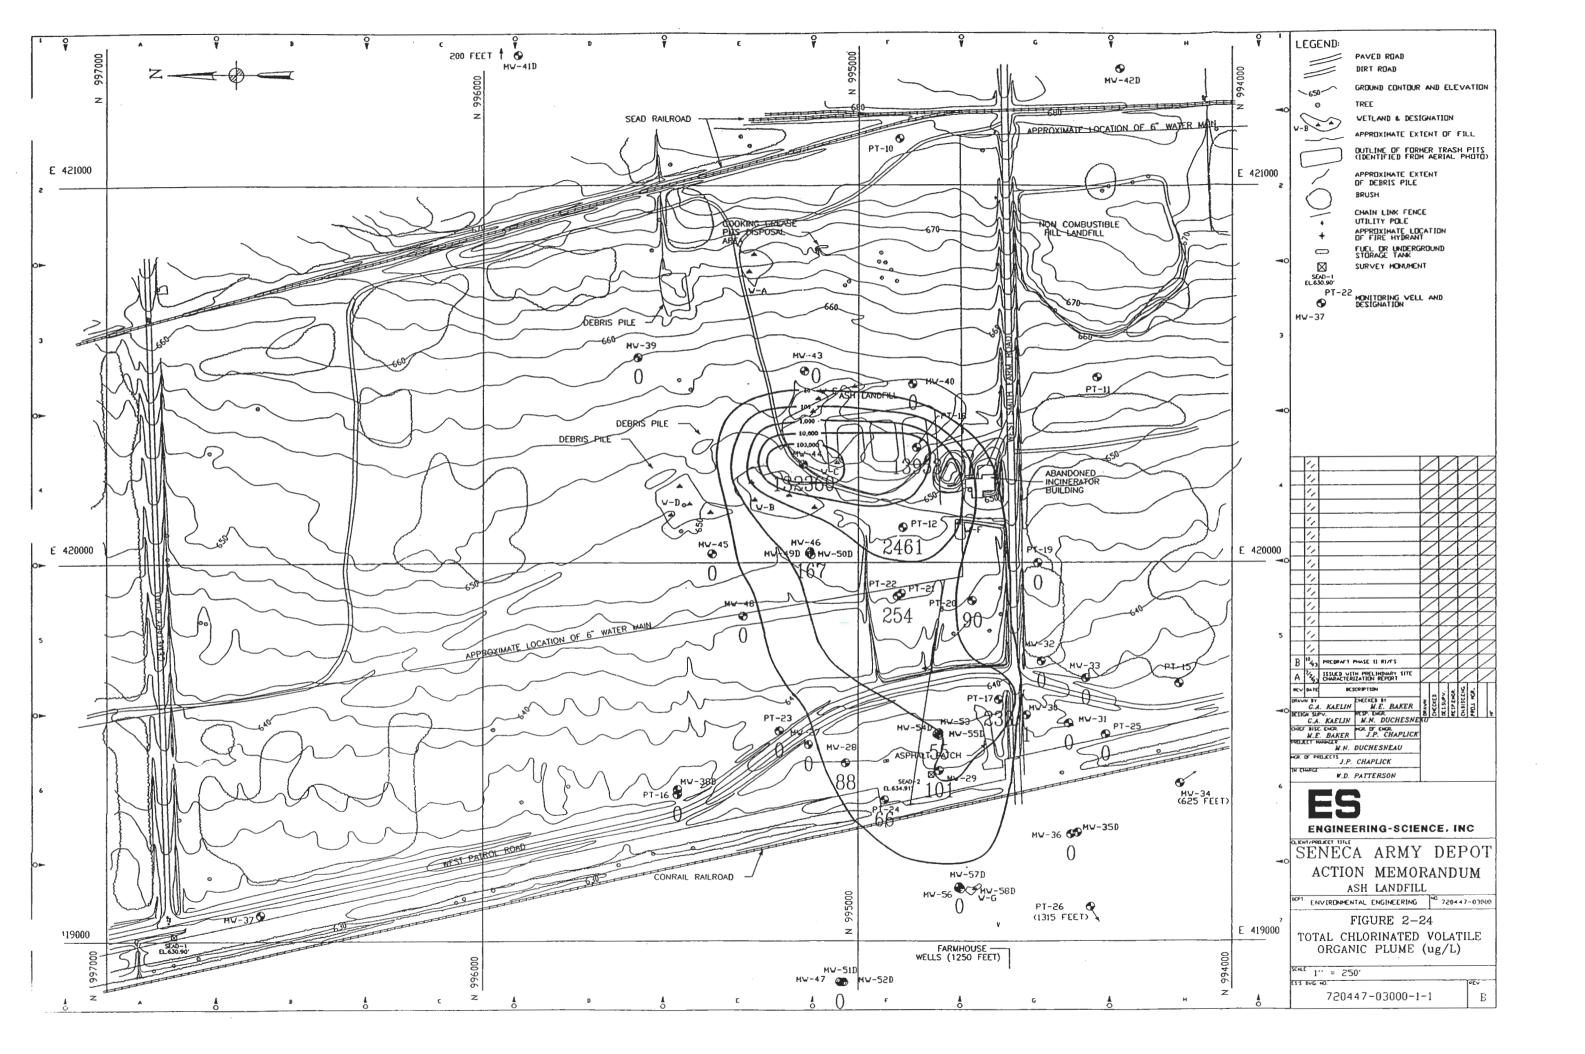

The geographic distribution of total volatile organic compounds is shown in Figure 2-24. Ten, 100, and 10,000 µg/L isocontours define a total volatiles plume that originates in the western portion of the Ash Landfill and extends to the west in the direction of groundwater flow. The plume is believed to extend beyond the fence near the Conrail railroad line onto the adjacent property based on the 104 μ g/L concentration of total volatiles in well PT-24.

As shown on Figure 2-24 the plume is relatively long and narrow; however, based on soil gas results and soil analyses, the source area for this plume is believed to extend as much as 300 feet north of PT-18, towards the bend in the road area. Because the source area is suspected to be wider than shown, the north and northeastern portions of the plume are bound by dashed or (inferred) 10 and 100 μ g/L isocontours. Well MW-40 in the eastern portion of the Ash Landfill clearly defines the eastern extent of the plume while wells PT-19, MW-32 and MW-31 define its southern extent.

TCE is considered as the dominant volatile organic compound present. Concentrations of TCE are up to 11,000 μ g/L in the source area (PT-18) and are as low as 4 and 1 μ g/L near the western boundary of the site. A more detailed plume characterization is in the RI report (ES, 1993).

Several daughter products of the breakdown of TCE have been observed at the site. They include 1,2-DCE and vinylchloride. At the downgradient, western end of the plume, 1,2-DCE is the dominant volatile organic compound where it is found at 100 and 71 µg/L in wells PT-24 and MW-29, respectively. The shift from TCE as the predominant volatile organic compound near the source areas to the dominance of the breakdown daughter compound 1,2-DCE at downgradient locations is consistent with the environmental chemistry of TCE.

Page 2-64 May, 1994

2.6.3.2 Other Priority Pollutants

No semi-volatile organic compounds, pesticides, PCBs, or herbicides were detected in any of the well samples collected.

Both unfiltered (total) and filtered (dissolved) groundwater samples were collected. Generally, filtered metals concentrations are less than concentrations in unfiltered samples, with most metals concentrations below the detection limit in the filtered samples.

Some of the highest unfiltered metals concentrations were obtained in well PT-26, near the Seneca airfield. PT-18 in the Ash Landfill also exhibits some high unfiltered concentrations of metals especially lead (17.8 μ g/L), zinc (496 μ g/L), manganese (1,530 μ g/L), and mercury (0.42 μg/L). Elevated concentrations of barium, beryllium, cadmium, chromium, lead, manganese, vanadium, and zinc occur in unfiltered samples from wells MW-29 and MW-31.

Cyanide concentrations (unfiltered only) were all below the detection limit of $10 \mu g/L$, except in PT-10 where 11.2 μ g/L were detected.

2.6.3.3 Additional Parameters

Several of the groundwater samples were analyzed for additional water quality parameters. The results are presented in Table 2-8. Generally, most of the concentrations were similar from well to well; however, anomallously high concentrations are noted in wells PT-17 (chloride) and PT-23 (Chemical Oxygen Demand and Total Suspended Solids).

2.6.4 Test Pits

Several test pits were excavated in locations where Ground Penetrating Radar (GPR) characterization of magnetic anomalies (measured by EM-31 device) indicated a possible pipe or drum signature. A total of 10 excavations were performed, five in the ash landfill and debris pits and five on the Non-Combustible Fill Landfill.

Test pits were excavated to up to 5 feet deep using a backhoe. Upon completion all excavated material was returned to the pit and covered. Test pit logs are included in the Phase II RI report.

Page 2-66 May, 1994

SENECA ARMY DEPOT ASH LANDFILL

TABLE 2-8 CONCENTRATIONS OF ADDITIONAL PARAMETERS IN GROUNDWATER (mg/L)

16.10	Moni	toring Wells	
	PT-17	PT-23	MW-42D
Parameter	(till/weathered	shale)	(bedrock)
Biological Oxygen Demand	1.9	4.6	1.2

Total Dissolved Solids	405	282	600
Total Suspended Solids	180	2370	150
Total Organic Carbon	1.9	1.9	1.6

SENECA ASH LANDFILL FINAL EE/CA

Two of the test pits (TP-6 and TP-7) were completed in and around the bend in the road area. These pits contained debris mixed with fill at depths of 0.5 to 4 feet. The debris was covered with fill and underlain by 3 to 4 feet of native soil. Bedrock was encountered at approximately 7 to 9 feet. No drums were found in any of the test pits. Metal debris, such as culverts or milk containers, were found and presumed to be the likely cause of the geophysical anomalies. Debris accounted for approximately 10% of the total volume.

2.6.5 Contamination Assessment Summary

As discussed above, the primary constituents of concern at the site are TCE and DCE. These are the most prevalent analytes in the soil and the major contributors to the groundwater plume, present in the groundwater. Contamination from other chemicals such as the petroleum residues, PCBs, pesticides, and herbicides appears to be limited, since these compounds were generally found in only a few samples.

The focus of this removal action will be TCE and DCE, along with the daughter product vinyl chloride, since these are the main groundwater contaminants, and since these compounds were found in almost all of the soil samples. Other contamination will be addressed during the remedial actions at the depot as outlined in the phase II RI/FS report.

The contamination at the site was delineated by the 1993 soil headspace survey. As shown in Figure 2-18, the source areas of the contamination consist of two noncontiguous areas, as defined by the 50 Vs contour line developed from the soil headspace survey. The results of the volatile organic analyses from the borings collected just outside these two areas showed that TCE, DCE, and vinyl chloride did not exceed the cleanup criteria. Therefore, these two areas will be used to define the areas for remediation.

2.7 RISK EVALUATION

2.7.1 Threats to Human Health

The contamination at the SEDA Ash Landfill poses a threat to public health or welfare through several mechanisms. The primary threat is through exposure to contaminated groundwater. As shown in the risk assessment conducted for the RI, volatile organics in groundwater pose a threat to human health. In addition, the risks posed by the other

May, 1994 Page 2-68

SENECA ASH LANDFILL FINAL EE/CA

constituents (i.e., metals, SVOC) fall within or below the EPA target ranges. TCE and its breakdown products are already present in the groundwater, and the plume is known to have migrated slightly off the site. The presence of TCE, DCE and vinyl chloride in the soil also pose a potential threat of airborne exposure through volatilization. Finally, the impacted soil may pose a threat through occasional soil exposure to existing SEDA post personnel or to the general public in the future should the post property be opened to residential use. Tables 2-5 through 2-8 summarize the analytical results for the soil samples collected as part of the RI. These tables include results for volatile and semivolatile organic compounds, and metals. Several of these concentrations (most notably TCE and DCE) exceed the New York State guidelines for soil cleanup, as discussed in Section 3 of this report. The New York State soil cleanup values are designed to be protective of human health by limiting the concentration of contaminants in the soil to below levels at which these contaminants would become a health threat through the groundwater pathway.

2.7.2 Threats to the Environment

The threats to the environment posed by the site have been quantified and indicate. It is believed that there is a threat of exposure through the air pathway or soil exposure to the animal population on the site. Surface water in Wetland B or groundwater discharge to surface water poses a threat to ecological life.

2.8 REMOVAL ACTION JUSTIFICATION

The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) states that a removal action may be conducted at a site when there is a potential threat to public health, public welfare, or the environment. An appropriate removal action is undertaken to abate, minimize, stabilize, mitigate, or eliminate the release or the threat of release at a site. Section 300.415(b)(2) of the NCP outlines factors to be considered when determining the appropriateness of a removal action, such as high levels of hazardous substances, pollutants, or contaminants in soils, largely at or near the surface, that may migrate; or the threat of fire or explosion.

Once it is determined that a removal action is appropriate, the removal is designated an emergency, time-critical, or non-time-critical removal. Emergencies are those situations in which response actions must begin within hours or days after the completion of the site

Page 2-69 May, 1994

SENECA ASH LANDFILL FINAL EE/CA

Time-critical removals are those in which, based on a site evaluation, it is evaluation. that less than 6 months remains before response actions must begin. determined Non-time-critical removals are those in which it is determined that more than 6 months may pass before response actions must begin. Since more than 6 months may pass before this removal action begins, this removal action is considered a voluntary, non-time-critical removal action.

Investigations of the SEDA Ash Landfill indicate that soils at this site pose a potential threat to human health and the environment through soil ingestion or dermal contact, and through continued leaching to the groundwater which passes through the site. This EE/CA was prepared to document the identification and evaluation of removal action alternatives in support of this voluntary non-time-critical removal action.

May, 1994 Page 2-70

3.0 REMOVAL ACTION OBJECTIVES AND SCOPE

GENERAL STATEMENT OF THE REMOVAL ACTION OBJECTIVES 3.1

Removal action objectives and site-specific considerations are developed as a basis for identifying appropriate removal action alternatives. Removal action objectives must protect human health and the environment, and address contaminants of concern, exposure routes, and receptors. Applicable or relevant and appropriate requirements (ARARs) that establish cleanup standards are also used to identify removal action objectives. In New York State, the acronym ARARs is not used, but is replaced with the term New York State Standards, Criteria, and Guidelines (SCGs), as presented in the NYSDEC Technical and Administrative Guidance Memorandum (TAGM) #HWR-90-4030. The removal action must be compatible with long-term remedial objectives at the site.

There are several general objectives to be considered for this removal action. One goal is to achieve a permanent solution, one which removes the threat to human health or the Another objective is treatment. A removal objective which treats the contaminants, as opposed to moving the contaminants to another location, is preferred.

This removal action for the SEAD Ash Landfill is not financed by Superfund therefore, the requirements of the NCP in Section 300.415(b)(5) for fund-financed removal actions do not apply.

3.2 ARARS STANDARDS, CRITERIA AND GUIDELINES (SCGS)

Pursuant to Section 300,415(i) of the NCP, the removal action for the site "shall, to the extent practicable considering the exigencies of the situation, attain applicable or relevant and appropriate requirements under federal environmental or state environmental or facility siting laws." ARARs are used to identify removal action objectives, formulate removal action alternatives, govern the implementation and operation of a selected removal action, and evaluate the appropriate extent of site cleanup.

In 40 CFR 300.5, EPA defines applicable requirements as those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that specifically address a

Page 3-1 May, 1994

SENECA ASH LANDFILL FINAL EE/CA

hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance found at a CERCLA site. Only those state standards that are identified by a state in a timely manner and that are more stringent than federal requirements may be applicable. Relevant and appropriate requirements are defined as those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that, while not "applicable" to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site. Only those state standards that are identified in a timely manner and are more stringent than federal requirements may be relevant and appropriate.

Any standard, requirement, criterion, or limitation under any federal environmental or state environmental or facility siting law may be either applicable or relevant and appropriate to a specific action. The only state laws that may become ARARs are those promulgated such that they are legally enforceable and generally applicable and equivalent to or more stringent than federal laws. A determination of applicability is made for the requirements as a whole, whereas a determination of relevance and appropriateness may be made for only specific portions of a requirement. An action must comply with relevant and appropriate requirements to the same extent as an applicable requirement with regard to substantive conditions, but need not comply with the administrative conditions of the requirement.

Three categories of ARARs have been analyzed: chemical-specific, location-specific, and action-specific. Chemical-specific ARARs address certain chemicals or a class of chemicals and relate to the level of contamination allowed for a specific pollutant in various environmental media (water, soil, air). Location-specific ARARs are based on the specific setting and nature of the site. Action-specific ARARs relate to specific actions proposed for implementation at a site.

3.2.1 Chemical-Specific ARARs

Chemical-specific ARARs are usually health or risk-based standards limiting the concentration of a chemical found in or discharged to the environment. They govern the extent of site remediation by providing actual cleanup levels, or the basis for calculating such levels for

May, 1994 Page 3-2

SENECA ASH LANDFILL FINAL EE/CA

specific media. These requirements may apply to air emissions during the removal action. A number of federal and state regulations may be used for this site. These include the following:

Air Quality

- 40 CFR Part 50.8 (applicable): Ambient Air Quality Standard for Carbon Monoxide. Carbon monoxide concentrations in the ambient air shall not exceed the following hourly average, 35 parts per million (ppm); 8-hour average, 9 ppm.
- 40 CFR Part 50.12 (applicable): Ambient Air Quality Standard for Lead. Lead concentrations in the ambient air shall not exceed 1.5 micrograms lead per cubic meter of air, 90-day average.
- 40 CFR Part 50.9 (applicable): Ambient Air Quality Standard for Ozone. concentrations in the ambient air shall not exceed 0.10 ppm hourly average.
- 40 CFR Part 50.6 (applicable): Ambient Air Quality Standard for PM-10. PM-10 concentrations in the ambient air shall not exceed the following: 24—hour average, 150 micrograms per cubic meter of air; annual average, 50 micrograms per cubic meter of air.
- 40 CFR Part 61 (applicable and relevant and appropriate): National Emission Standards for Hazardous Air Pollutants. This regulation requires the minimization of emissions, specifies emissions tests and monitoring requirements, and sets limits on several hazardous air pollutants.
- 40 CFR Part 58 (applicable): Ambient Air Quality Surveillance. This part defines quality assurance requirements, monitoring methods, instrument siting, and operating schedule for ambient air quality surveillance.
- 40 CFR Part 52 (applicable): Approval and Promulgation of Implementation Plans. This part defines general provisions for the contents of State Implementation Plans (SIPs).

Page 3-3 May, 1994

SENECA ASH LANDFILL FINAL EE/CA

6 NYCRR Part 256 (applicable): Air Quality Classification System. This regulation defines four general levels of social and economic development for geographical areas in New York. These levels range from Level I, which would be used for timber, dairy farming or recreation and would be sparsely populated, to Level IV, which would be densely populated with large commercial metropolitan office buildings or areas of heavy industry. SEAD is classified as Level II, which is an area of predominantly single and two family residences, small farms and limited commercial services and industrial development.

- 6 NYCRR subpart 257-1 (applicable): Air Quality Standards General. This section of the air regulations defines what an air standard is, how the standard will be applied and what compliance with these standards will entail.
- 6 NYCRR subpart 257-3 (applicable): Air Quality Standards-Particulates. Suspended particulates shall not exceed 250 mg/m³ more than once a year. Annual standard -55 $\mu g/m^3$, 30-day standard - 100 $\mu g/m^3$, 60-day standard - 85 $\mu g/m^3$, 90-day standard - 80 μg/m³, standard for settleable solids - 50 percent of the values of the 30 day average concentrations shall not exceed 0.30 mg/cm²/mo; - 84 percent shall not except 0.45 mg/cm²/mo.
- 6 NYCRR subpart 257-4 (applicable): Air Quality Standards for Carbon Monoxide. Eight hour standard - 9 ppm, 1 hour standard 35 ppm.
- 6 NYCRR subpart 257-6 (applicable): Air Quality Standards Hydrocarbons (non methane). Three hour standard measured from 6 to 9 am - 0.24 ppm.
- NYSDEC Air Guide 1 To Be Considered (TBC): This document provides guidance for the control of toxic ambient air contaminants in New York state including guidance on the following contaminants of concern.

33.000 µg/m³ Short-term Guideline Concentration (SGC);4.5 E-Trichloroethene -

01 μg/m³ Annual Guideline Concentration (AGC)

 $14,000 \,\mu g/m^3 \,SGC; \,1900.0 \,\mu g/m^3 \,AGC$ Dichloroethene -

1300 $\mu g/m^3$ SGC; 2.0 E -02 $\mu g/m^3$ AGC Vinyl Chloride -

May, 1994 Page 3-4 K:\Seneca\EECA\Section.3

SENECA ASH LANDFILL FINAL EE/CA

Water Quality

There are a number of water quality standards which are potential ARARs for this removal action. These are summarized in Table 3-1 and described below.

- 40 CFR Part 131 (applicable): Water Quality Standards. This part implements Section 101 of the Clean Water Act (CWA), which specifies the national goals of eliminating the discharge of pollutants, prohibiting the discharge of toxic pollutants in toxic amounts, and implementing programs for control of nonpoint sources.
- 40 CFR Part 131.12 (applicable): Antidegradation Policy. Establishes standards to prevent a body of water which has an existing high standard from degrading to a lower standard.
- 40 CFR Part 141 (applicable): National Primary Drinking Water Regulations. This part establishes primary drinking water regulators pursuant to Section 1412 of the Public Health Service Act as amended by the Safe Drinking Water Act.
- 40 CFR Part 141.11 (applicable): Maximum Inorganic Chemical Contaminant Levels. This section establishes maximum contaminant levels (MCLs) for inorganic chemicals including the following:

Constituent	Level (mg/L)
Arsenic	0.05
Barium	1.0
Cadmium	0.010
Chromium	0.05
Lead	0.05
Mercury	0.002
Selenium	0.01

Note:

SDWA = Safe Drinking Water Act. MCL = Maximum Contaminant Level

MCLG = Maximum Contaminant Level Goal

DWQS = New York Primary Drinking Water Quality Standard

AWQC = EPA ambient water quality criteria.

W & F = AWOC for the protection of human health from the ingestion of water and aquatic organisms.

F = AWQC for the protection of human health from the ingestion of aquatic organisms, only.

WS = water source

B = bioaccumulation

POC = Principle Organic Contaminant

PCB = polychlorinated biphenyl.

mg/L = milligrams per liter.

ug/L = micrograms per liter.

umho/cm = micromhos per centimeter.

Secondary MCLs are not potential ARARs but are To Be Considered (TBCs) and have been included for comparison purposes only

- (a) 40 CFR 141
- (b) 10 NYCRR Part 5
- (c) Water Quality Criteria Summary, US EPA, 1991 (d) 6 NYCRR Parts 701 705, and NYS TOGS 1.1.1, November 15, 1991
- (e) pH Dependent Criteria (f) Value for total chromium.

- (g) Value for trivalent arsenic.
 (h) Hardness—dependent criteria assumes water hardness of 100 mg/L calcium carbonate.
 (i) Value for listed principle organic contaminants; total for principle and unspecified organic contaminants may not exceed 100 ug/L.
- (i) Value for total tribalomethanes (chloroform, bromodichloromethane, dibromochloromethane, and bromoform).
- (k) Value for total halomethanes; includes chloromethane, bromomethane, dichloromethane, bromodichloromethane, tribromomethane, dichlorodifluoromethane, and trichlorofluoromethane
- (1) Value for total chlorinated benzenes.
- (m) Value for total dichloroethenes.
- (n) Value for total 1,3-dichloropropenes.
- (o) Value for listed unspecified organic contaminants; total for principle and unspecified organic contaminants may not exceed 100 ug/L.
- (p) Value for total phthalate esters.

 40 CFR Part 141.12 (applicable): Maximum Organic Chemical Contaminant Levels. This section establishes MCLs for organic chemicals including the following:

Constituent	Level (mg/L)
TCE	0.005
Benzene	0.005
Total trihalomethanes	0.10

- 40 CFR Part 264 Subpart F (relevant and appropriate): Releases from Solid Waste Management Units. Standards for protection of groundwater are established under this citation.
- 40 CFR Part 403 (applicable): Pretreatment Standards for the Discharge of Treated Site Water to a Publicly Owned Treatment Works (POTW). This part establishes pretreatment standards for the discharge of wastewater to POTWs.
- 6 NYCRR Chapter X (relevant and appropriate): This chapter establishes the requirements of the State Pollutant Discharge Elimination System.
- 6 NYCRR subparts 701 and 702 (applicable): These subparts establish surface water standards for protection of drinking water and aquatic life.
- 6 NYCRR subpart 703 (applicable): This subpart establishes groundwater standards specified to protect groundwater for drinking water purposes.
- 6 NYCRR subpart 375 (relevant and appropriate): This subpart contains the New York State rules for inactive hazardous waste disposal sites.
- 6 NYCRR subpart 373-2.6 and 373-2.11 (applicable): This regulation requires groundwater monitoring for releases from solid waste management units.
- 6 NYCRR subpart 373-2 (relevant and appropriate): This regulation establishes
 postclosure care and groundwater monitoring requirements.

May, 1994

Page 3-10

K:\Seneca\EECA\Section.3

10 NYCRR Part 5 (relevant and appropriate): This regulation establishes criteria for drinking water supplies. Specifically, NYSDOH has established MCLs for water. The MCL for lead is 0.015 mg/L, which is more stringent than the federal MCLs.

NYSDEC TOGS 1.1.1 (relevant and appropriate): This document compiles water quality standards and guidance values for use in NYSDEC programs.

Soil Quality

- 40 CFR Part 268 (relevant and appropriate): Land Disposal Restrictions. Restricts the disposal of listed and characteristic hazardous waste which contain hazardous constituents exceeding designated levels. Only applies when the waste is "placed" on the land. Only the restrictions on land disposal of TC hazardous wastes are ARARs; there are no listed wastes onsite. Specifically, the criteria for D008 (lead) and D040 (trichloroethene) are ARARs.
- 40 CFR subpart S parts 264.552 and 264.533 (relevant and applicable): Corrective Action for Solid Waste Management Action for Solid Waste Management Units. Allows for the consolidation of wastes, or the replacement of remediated wastes in land based units without invoking the RCRA land-disposal requirement of 40 CFR 268.
- 6 NYCRR subpart 375 (relevant and appropriate): This subpart contains the New York State rules for inactive hazardous waste disposal sites. Specifically, cleanup levels for hazardous constituents in soil have been proposed by the State of New York through Technical and Administrative Guidance Manuals (TAGMs). NYSDEC TAGM manual for cleanup levels for soils is #HWR-92-4046 and has been used as guidance for this remedial action. These levels are shown in Table 3-2 for constituents detected at the Ash Landfill. The primary chemicals of concern at the SEAD Ash Landfill for this removal action are chlorinated hydrocarbons, specifically TCE, DCE, and vinylchloride. A review of the data presented in Section 2 indicates that some semi-volatile organic compounds and some metals also exceed the established TAGM values. The final management of these materials will be the focus of the ultimate Record of Decision (ROD) and are not the focus of this action.

- 2. Based upon NYSDEC Water Quality Standards
- 3. NYSDEC TAGM #HWR-92-4046, November 16, 1992

The potential ARARs for soils for this removal action are summarized in Tables 3-2 and 3-3. Site Cleanup Goals (SCG) for metals have been determined as either the site background concentration or the NYSDEC TAGM value, whichever is higher. The background metal concentration value has been determined as the 95th Upper Confidence Limit (UCL) for the entire SEAD facility.

PCBs

- 40 Part 761 (TBC): Polychlorinated Biphenyls (PCBs) Manufacturing, processing, distribution in commerce and use prohibition. This part establish and the requirements for the storage and disposal of PCBs. No action is required in regards to this regulation.
- This regulation 40 Part 761 subpart G (TBC): PCB Spill Clean Up Policy, establishes criteria EPA will use to determine the adequacy of the clean up of spills resulting from the release of materials containing PCBs. No action is required in regards to this regulation since the concentrations of PCBs at the Ash Landfill are less than 50 ppm.

3.2.2 Location-Specific ARARs

Location-specific ARARs govern natural site features such as wetlands, floodplains, and sensitive ecosystems, and manmade features such as landfills, disposal areas, and places of historic or archaeological significance. These ARARs generally restrict the concentration of hazardous substances or the conduct of activities based solely on the particular characteristics or location of the site. Federal and State regulations which may apply to this removalaction include the following:

Endangered Species

40 CFR Part 257.3-2 (relevant and appropriate): Facilities or practices shall not cause or contribute to the taking of any endangered or threatened species.

SB - Site Background

NA - Not Available

Location Standards

40 CFR Part 264.18 (relevant and appropriate): Location Standards for Hazardous Waste Facilities. The general requirements for locating a hazardous treatment, storage, or disposal facility are found in this section. They include provisions for seismic considerations and floodplains.

40 CFR Part 241.202 (applicable): Site selection shall be consistent with public health and welfare. It shall also be consistent with land-use plans and air and water quality standards.

Antiquities

- 16 USC Part 469a-1 (applicable): The Archaeological and Historic Preservation Act requires that action be taken to recover and preserve artifacts.
- 36 CFR Part 800 (relevant and appropriate): Action must be taken to preserve historic properties. Actions must be planned to minimize harm to national historic landmarks.

3.2.3 Action-Specific ARARs

Action-specific ARARs are usually technology- or activity-based- limitations that control actions at hazardous waste sites. Action-specific ARARs generally set performance or design standards, controls, or restrictions on particular types of activities. To develop technically feasible alternatives, applicable performance or design standards must be considered during the development of all removal alternatives. Action-specific ARARs are applicable to this site. The action-specific ARARs to be used will be determined by the Army based upon the technology chosen. Federal and State regulations which may apply include the following:

Solid Waste Management

- 40 part CFR 241,100 (relevant and appropriate): Guidelines for the Land Disposal of Solid Wastes. These regulations are geared specifically toward sanitary landfills; however, they are applicable to all forms of land disposal and land-based treatment.
- 40 CFR Part 241.204 (applicable): Water Quality. The location, design, construction, and operation of land disposal facilities shall protect water quality.

Page 3-15 May, 1994

40 CFR Part 241.205 (applicable): The design, construction, and operation of land disposal facilities shall conform to air quality and source control standards.

- 40 CFR Part 257.1 (relevant and appropriate): This part establishes the scope and purpose of criteria for use in assessing the possibility of adverse effects on health or the environment from solid waste disposal operations.
- 40 CFR Part 257.3 (relevant and appropriate): This part establishes criteria to assess the impact of disposal operations, including such considerations as floodplains, endangered species, air, surface water, groundwater, and land used for food-chain crops.
- 40 CFR Part 243.202 (relevant and appropriate): This part specifies the requirements for transporting solid waste, including provisions to prevent spillage.

Hazardous Waste Management

- 40 CFR 262.11 (applicable): This regulation requires a person who generates a solid waste to determine if that waste is a hazardous waste.
- 40 CFR Part 263.30 and 263.31 (relevant and appropriate): These regulations set forth the standards and requirements for action in the event of a release during transport.
- 40 CFR Part 264 (relevant and appropriate): This part establishes hazardous waste management facility standards and requirements. The onsite disposal areas used for stockpiling, mixing, and extended bioremediation of wastes must meet the substantive requirements of 40 CFR subparts B (general facility standards), E (manifest system, record keeping, and reporting), F (releases from solid waste management units), G (closure and postclosure), L (waste piles), M (land treatment), and N (landfills). These regulations are applicable for hazardous wastes and are also relevant and appropriate for certain wastes which are not hazardous wastes.
- 40 CFR Part 270 subpart C (relevant and appropriate): This regulation establishes permit conditions, including monitoring, recordkeeping requirements, operation and maintenance requirements, sampling, and monitoring requirements. Although no permit is required for activities conducted entirely on site, the substantive requirements of these provisions are relevant and appropriate.

Page 3-16 May, 1994

40 CFR Part 270 subpart B (relevant and appropriate): This part defines the The required contents of a hazardous waste management permit application. substantive requirements of these provisions are relevant and appropriate.

Occupational Health and Safety Administration

- 29 CFR Part 1910.50 (applicable): Occupational Noise. No worker shall be exposed to noise levels in excess of the levels specified in this regulation.
- 29 CFR Part 1910.1000 (applicable): Occupational Air Contaminants. The purpose of this rule is to establish maximum threshold limit values for air contaminants to which it is believed nearly all workers may be repeatedly exposed day after day without adverse health effects. No worker shall be exposed to air contaminant levels in excess of the threshold limit values listed in the regulation.
- 29 CFR Part 1910.1200 (applicable): This part requires that each employer compile and maintain a workplace chemical list which contains the chemical name of each hazardous chemical in the workplace, cross-referenced to generally used common names. This list must indicate the work area in which each such hazardous chemical is stored or used. Employees must be provided with information and training regarding the hazardous chemicals.
- 29 CFR Part 120 (applicable): This part applies to employers and employees engaged in sites that have been designated for cleanup, and other work related to RCRA and CERCLA. The regulation establishes proceedings for site characterization and control, and requirements for employee training and medical monitoring.

Transportation of Hazardous Waste

- 49 CFR Part 171 (applicable): General information, regulations, and definitions. This regulation prescribes the requirements of the DOT governing the transportation of hazardous material.
- 40 CFR Part 172 (applicable): Hazardous materials table, special provisions, Hazardous Materials Communications, Emergency Response Information, and Training requirements. This regulation lists and classifies those materials which the DOT has designated to be hazardous materials for the purpose of transportation and

Page 3-17 May, 1994

prescribes the requirements for shipping papers, package marking, labeling and transport vehicle placarding applicable to the shipment and transportation of those hazardous materials.

- 49 CFR Part 177 (applicable): Carriage by Public Highway. This regulation prescribes requirements that are applicable to the acceptance and transportation of hazardous materials by private, common, or contract carriers by motor vehicle.
- 6 NYCRR Chapter 364 (applicable): New York Waste Transport Permit Regulation. This regulation governs the collection, transport, and delivery of regulated waste originating on terminating within the state of New York.
- EPA/DOT Guidance Manual on hazardous waste transportation (TBC):

Incineration

- 40 CFR Part 264 Subpart O (relevant and appropriate): This regulation establishes performance standards and monitoring requirements for hazardous waste incinerators.
- 6 NYCRR Subpart 373-2.15 (relevant and appropriate): This regulation establishes performance standards and monitoring requirements for hazardous waste incinerators for New York State.

REMOVAL ACTION OPTIONS 4.0

4.1 **EVALUATION METHODOLOGY**

The purpose of this removal action is to remove the source of TCE and DCE and thereby reduce the further degradation of groundwater and soils. Other analytes such as PAHs and metals are not a direct concern of this action and the ultimate disposition of these materials will be determined as part of the overall RI/FS process. This section discusses the methodology which was employed to select the appropriate treatment technology for this removal action. The evaluation followed the EPA RI/FS guidance, where applicable.

The first step in the technology selection process was to screen potential technologies based upon their demonstrated ability to treat soil impacted with TCE and DCE. This process accounted for site specific conditions including geology, hydrogeology, and the nature and extent of contamination. Other factors considered in the initial screening evaluation included the permenance of the solution, in regards to removing the source of TCE and DCE contamination and the potential effect on future remediation operations.

Those technologies passing the initial screening process were further evaluated. The purpose of evaluating removal action options is to provide decision makers with sufficient information to select the most appropriate technology for the removal action. The evaluation of each option was based on three criterion - effectiveness, implementability, and cost.

The first evaluation criterion considered was effectiveness. This criterion as defined in "Guidance for Conducting Remedial Investigation and Feasibility Studies under CERCLA" (EPA, 1988c) focuses on (1) the potential effectiveness of process options in handling the estimated areas and volumes of contaminated soils and meeting the removal action clean up objectives; (2) the potential impacts to human health and the environment during the construction and implementation phase; and (3) how proven and reliable the process is with respect to the contaminants and conditions at the site. Factors considered in the evaluation of effectiveness included the following:

- protection of the community during the removal action
- protection of workers during the removal action
- threat reduction

Page 4-1 May, 1994 K:\Seneca\EECA\Section.4 time until the removal action objectives are met

- compliance with ARARs
- impact to the environment
- potential exposure to remaining risks
- reduction of toxicity, mobility, or volume
- long-term effectiveness and permanence
- long term remediation goals

Implementability encompasses both the technical and administrative feasibility of implementing a technology process. Technical feasibility refers to the ability to construct, reliably operate and meet the technology-specific regulations taking into account specific site conditions. Administrative feasibility refers to the ability to obtain approvals from the various agencies, the availability of treatment, storage and disposal services and capacity, and the requirements for, and availability of, specific equipment and technical specialists. In summary, factors which were examined in regards to implementability included the following:

- technical feasibility
- administrative feasibility (including availability)

Preliminary cost estimates were developed for each alternative based upon published information, guidance documents, vendor quotes, and engineering judgement. These estimates are not meant to be definitive, but serve as a basis for comparison. Costs considered included capital costs and annual operating and maintenance (O&M) costs.

Capital costs consist of direct (construction) and indirect (nonconstruction and overhead) costs. Direct costs may include the following:

- construction costs
- equipment costs
- land and site development cost
- buildings and services costs
- disposal costs
- site restoration costs
- equipment decontamination costs

Page 4-2 May, 1994 K:\Seneca\EECA\Section.4

Indirect costs consist of the following:

- engineering costs
- license and permitting costs
- startup and shakedown costs
- contingency allowances

O&M costs are post construction costs necessary to ensure the continued effectiveness of the action. O&M costs may include the following:

- operating labor costs
- maintenance costs
- auxiliary materials and energy costs
- disposal of residues
- sampling and analysis fee
- administrative costs
- contingency costs

4.2 INITIAL SCREENING

There are three general categories of potential removal actions for remediating the contaminated soil in the "bend in the road" area: on-site treatment, on-site containment and off-site disposal. Treatment can be done in situ or ex situ. Containment actions, in which contaminated soils remain in situ, are meant to isolate or confine soil contaminants from the surrounding environment, thus limiting the movement of the contaminants into the soil, groundwater or air. For off-site disposal, contaminated soils will be excavated and shipped off-site for disposal in a permitted hazardous waste landfill.

Specific ex-situ treatment activities include excavation of contaminated soil and debris, treatment of contaminated materials using thermal, physical, chemical, or biological treatment technologies followed by disposal of the treated materials in permitted landfills, and/or backfilling of the treated materials on-site.

A number of treatment technologies can be conducted in situ: soil vapor extraction (either steam or vacuum), bioremediation, solidification, and vitrification. The treated media, after clean-up objectives have been met is then left in place.

Specific containment technologies include capping and the installation of subsurface barriers, such as slurry walls. The no-action alternative is a special case in this category. The no-action alternative must be considered when conducting a feasibility study under the NCP, but is not required when conducting an EE/CA. Containment technologies were eliminated as options during the initial screening because they do not offer a permanent solution.

A number of soil treatment technologies were considered for this removal action. These are shown in Table 4-1, which is a table prepared by the EPA for screening remediation technologies. After the initial screening analysis, this list of candidate options were reduced to three basic technologies which were then considered in detail (see Section 4.3). These technologies included: thermal desorption, soil vapor extraction, and incineration. Combinations of these techniques were also considered. Bioremediation. soil washing, vitrification solidification/stabilization were not evaluated in detail. Bioremediation of chlorinated solvents in soils is not a proven technology for treating chlorinated hydrocarbons as are the other selected technologies. Soil washing was not evaluated in detail because of the large quantities of contaminated water generated by the process, which would require the construction of a wastewater treatment plant. Vitrification was not evaluated in detail because vitrification is considered to be an effective technology for immobilization of metals, its effectiveness for organic contaminants has not been well documented. Solidification/stabilization has not been demonstrated to be effective for the treatment of VOCs such as TCE and DCE. demonstrate effectiveness, treatability studies would be required.

Each of the technologies evaluated in detail, including off-site disposal, is discussed below. Each discussion describes the technology, evaluates some of its positive and negative aspects, and compares estimated costs. Comparative costs were developed based on information contained in EPA guidance documents and from vendors and are provided for comparison only. These should not be considered as the final actual cost estimates, which can be completed only after the design is finalized.

Table 4-1 Soil Remediation Technologies (EPA, 1988a)

4.3 DETAILED ANALYSIS OF OPTIONS

4.3.1 Soil Vapor Extraction

Soil Vapor Extraction (SVE) systems withdraw air through soil in order to extract volatile organic compounds. A vacuum apparatus is used to create negative pressure in the soil to accomplish this. Volatile constituents partition to the air in the soil and are subsequently recovered. Typical systems consist of a vacuum extraction well or wells, an air/water separator, a vacuum pump, a carbon adsorption canister (though a catalytic/thermal oxidizer or vapor condenser may also be used), and associated vacuum gauges.

The extraction wells may be either horizontal or vertical. Horizontal wells are generally more effective in situations where the contaminated soil is shallow (less than 10 feet deep), as is the case at the SEAD Ash Landfill.

SVE systems are generally used in unsaturated soils. At sites such as the SEAD Ash Landfill, dewatering would be necessary during periods of the year, such as the spring, when the water table rises to near the surface. This could be accomplished separately from the SVE system by using either trenches or extraction wells. However, since the amount of water to be removed is likely to be small, since the aquifer thickness is thin and does not readily yield water, and the suction lift is only 10 to 15 feet it may be possible to simultaneously remove air and entrained water from the site by a strong vacuum system. Once the entrained water is separated from the air in an air/water separator, the water collected would be treated and discharged to either the nearby surface streams/drinage ditches or transported to the biological wastewater treatment plant.

4.3.1.1 Effectiveness

Vacuum extraction processes have proven to be effective remediating volatile contaminants from uncontrolled hazardous waste sites and are most commonly used in in-situ remedial actions (Murdoch, et al. 1988). These systems are commonly used for gasoline and other petroleum spills, and have been shown to be effective for a wide range of volatile organic contaminants. Typically, SVE systems are effective for compounds with a high vapor pressure, and/or a dimensionless Henry's Law constant greater than 0.001. TCE, for example, has a Henry's Law constant of 0.23 at 10°C. DCE and vinyl chloride have Henry's Law constants of 0.12 (cis-1,2-DCE), 0.25 (trans-1,2-DCE), and 0.65. (EPA, 1989c). A summary of ARAR compliance is shown in Table 4-2.

The use of SVE is most effective in permeable unsaturated soils, such as sands, gravels, and coarse silts since diffusion rates through dense soils, such as compacted clays, are much lower than through sandy soils (USEPA, 1988a). New techniques have been developed which increase the permeability of clay soils, thereby increasing the contaminant removal rates. These techniques include capping-which prevents the "short circuiting" of the vapor extraction well; air injection-which causes the fracturing of the clay matrix and thereby increases the permeability; and steam injection-which causes an increase in volatility of the organics as well as an increase in permeability.

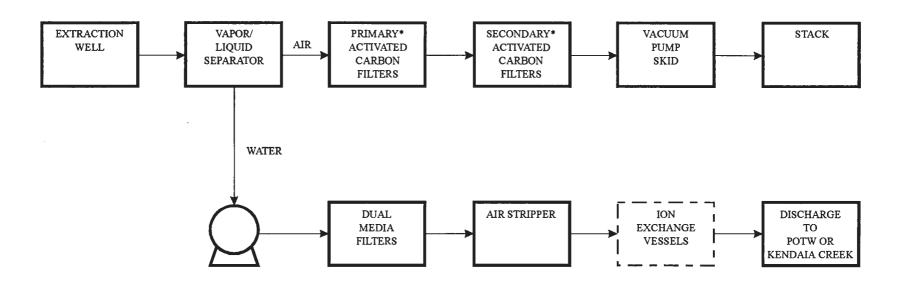

There are two primary effluents from an SVE system: air and water. The air is discharged after passing through the various treatment units. Typically, the air is passed through a condenser to remove water and some organics. The air is then passed through either carbon adsorption filters or a catalytic oxidizer/thermal. Air monitoring can be used to ensure that the air leaving the system meets the requirements of all ARARs. Figure 4-1 provides a typical block flow diagram for a SVE system.

The water effluent comes from two sources, the vacuum system and, if required, the dewatering system. This water can be treated in a variety of ways. At the SEAD Ash Landfill the water will likely be filtered, and then passed through an air stripper. The off-gas from the stripper will be treated in a catalytic oxidation unit or an activated carbon adsorption system. If metals in the recovered groundwater exceed allowable discharge criteria, the water could also be routed through ion exchange resins. The treated water could either be discharged to a local creek, or to the biological wastewater treatment system, depending on compliance with the water ARARs discussed above.

The principal pathway of community and worker exposure during removal activities would be through inhalation or contact with the soil during installation of the SVE system. Typical drilling equipment such as that used during the RI, will be used to install the SVE wells. It is anticipated that the community exposure will be acceptable, since ambient air monitoring conducted during the RI did not detect unacceptable air concentrations 100 feet from the drilling site. The nearest residence is approximately 2500 feet away. The fenceline for the site is over 200 feet away.

One potential drawback to using SVE at the Ash Landfill is the soils at the site. The soils are primarily clays and clay loams, which have low permeabilities. As discussed above, SVE can still be effective in these soils, but a large number of wells or some other permeability increasing technique will likely be necessary. This situation makes it difficult to predict the

Soil Vapor Extraction Blockflow Diagram

^{*} AS AN ALTERNATE CATALYTIC OXIDATION COULD BE USED

duration of the removal action and therefore accurately estimate the cost. Localized areas of dense soils could take 1.5 to 2 years to fully remediate.

4.3.1.2 **Implementability**

SVE is readily implementable at the SEAD Ash Landfill site. There are a number of vendors available who specialize in installing SVE systems including ETG Technologies, Inc.; VAPEX; and Terravac. Most of the equipment used for SVE is standard equipment, such as the extraction wells, injection wells, blowers, and pumps. This equipment is readily available and easy to maintain since replacement parts are also readily available.

Once the system is installed, the maintenance requirements are minimal. The treated water will likely be transported to be disposed at the SEDA biological treatment plant or discharged to the on-site drainage swales. Depending upon the concentration of vinyl chloride in the water activated carbon could be used for treatment of the air or water. Depending upon the treatment flow and the influent concentration the carbon canisters will need to be replaced periodically. Due to the low concentrations of organics and the relatively short time-frame for this removal action, it would not be practical to regenerate carbon on site. The spent carbon would be sent offsite for either regeneration or proper disposal. Other maintenance would be to routinely check all the equipment and make necessary repairs.

If the concentration of vinyl chloride is high, catalytic/thermal oxidation will be used as an alternative to carbon.

The set up time for implementing an SVE system is short. Since all of the equipment needed is standard, mobilization, site preparation and equipment installation is expected to take from between 2 and 4 weeks.

4.3.1.3 Cost

Treatment cost for soil vapor extraction obtained from vendors was approximately \$175 per cubic yard, based on site conditions. The total cost to treat 14,500 yards of soil would be approximately \$2,500,000. These costs include the following:

- engineering
- the development of work plans
- the development of health and safety plans

May, 1994 Page 4-18 K:\Seneca\EECA\Section.4

- permitting
- the development of sampling and analysis plans
- mobilization
- site development
- dewatering operations
- water treatment
- off gas treatment
- ambient air monitoring
- site restoration
- decontamination operations
- the disposal of secondary wastes
- demobilization
- confirmational sampling and analysis
- site supervision

These costs do not include oversight costs or contingency costs.

4.3.2 Thermal Desorption

Thermal desorption, otherwise known as low-temperature thermal stripping, is a process in which the contaminated soil is heated in order to vaporize the volatile organic contaminants. The vapor then passes through a series of air emission control units. contaminants are treated with catalytic or thermal oxidation, or a carbon adsorption system. Unlike incinerators in which the soil is subjected to high temperatures and combustion in the primary chamber, thermal desorbers heat the soil at lower temperatures and combust the vapor in air pollution control equipment prior to discharge. In some instances, activated carbon can be substituted for a thermal oxidizer.

There are two major types of thermal desorbers currently available. One set relies on indirect heating. The soil and the heat transfer medium, generally a synthetic oil or a molten salt do not contact each other. The other type of unit, a direct-heated device, is similar to a rotary kiln incinerator. The soils are heated in the unit by a flame which directly contacts the soil. The flame is only hot enough to promote volatilization and not incineration. Indirectly heated units maintain the soil at a higher temperature, while indirectly fired units tend to have a higher throughput.

The type of unit required depends on the nature of the contaminants present and the treatment criteria. Figure 4-2 shows a typical block flow diagram.

The thermal desorber is operated in the range of 300°F to 850°F, depending on the type of unit and the nature of the contaminants. For the SEAD Ash Landfill, a higher temperature may be necessary because of the presence of PAHs and other petroleum hydrocarbons at the site. PAH and petroleum compounds have higher boiling points than volatile organic compounds. If a thermal oxidizer is used for combustion, the operating temperature in this chamber is usually in the range of 1,500°F to 2,200°F. The primary advantage to this system over incineration is that only the vaporized

organics and water from the contaminated soil enter the combustion chamber, thus minimizing the residuals in the vapor, such as HCl and NO_x which must be removed.

Thermal desorption has been demonstrated effective for the removal of organics from contaminated soils. Specifically, thermal desorption has been used to treat soils contaminated with chlorinated hydrocarbons, petroleum hydrocarbons and PAHs, such as the SEAD Ash Landfill soils, to levels less than 10 mg/kg for total petroleum hydrocarbons and less than 0.1 mg/kg for specific chlorinated hydrocarbons. Thermal desorption is ineffective in removing metals, but the effluent from the thermal desorption unit could be stabilized prior to backfilling to prevent metals migration and to ensure that the treated soils meet the criteria for backfilling, if required.

There are potentially five effluents from this system: the treated soil, scrubber water, baghouse filters, spent carbon canisters, and debris. If an afterburner is used, no spent carbon is generated. The scrubber water may be treated and sent to the local wastewater treatment plant or discharged into Kendaia Creek. The spent carbon can be thermally regenerated and reused. The soil can be either backfilled or sent off-site for disposal. The baghouse filters can also be sent to an appropriate disposal facility. Debris can be segregated, sized, and washed. Some debris will also be suitable for thermal desorption. The treated debris would then be disposed of on-site or sent off-site for additional treatment and disposal.

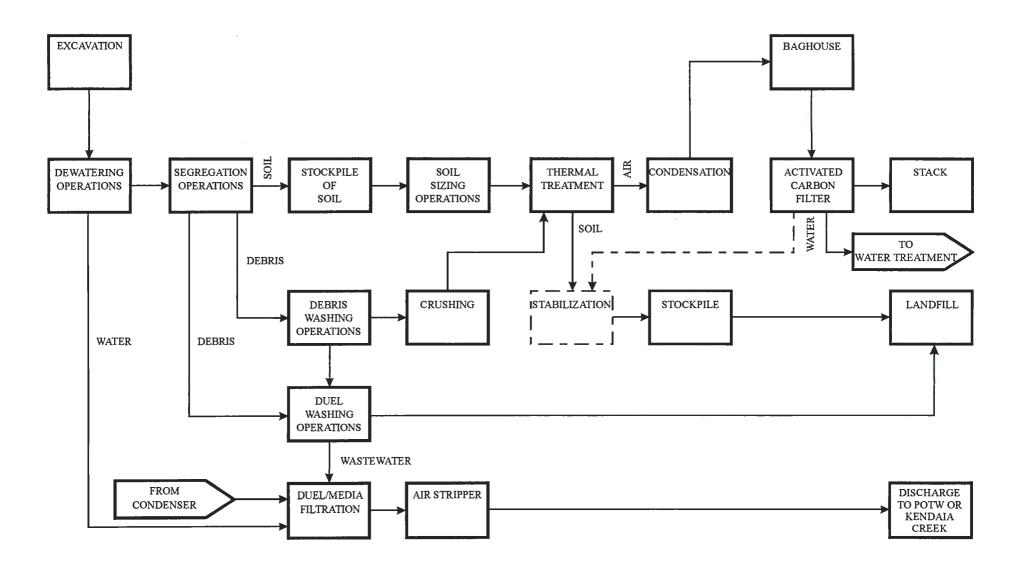

Air emissions controls are an integral part of these units. In addition to the organic controls, baghouses and scrubbers are often used. Scrubbers are used to remove acid gases, and baghouses are used to remove particulate matter. Scrubber effluent can be passed through a carbon system and reused. The exact configuration of the emissions controls depends on the design of the thermal desorber and the characteristics of the contaminated soil.

May, 1994

Page 4-20

K:\Seneca\EECA\Section.4

Thermal Desorption Blockflow Diagram

4.3.2.1 Effectiveness

Thermal desorption has been demonstrated effective for the removal of organics from contaminated soils. Specifically, thermal desorption has been used to treat soils contaminated with chlorinated hydrocarbons, such as the SEAD Ash Landfill soils, to levels less than 0.1 mg/kg. Thermal desorption is ineffective in treating metals, however metals are not the focus of this effort.

Thermal desorption has been used at a number of sites. For example, Canonie Environmental has successfully used their process at the Cannons Bridgewater Superfund Site in Massachusetts, the Mckin Superfund site in Maine, and the Ottati and Goss Superfund Site in New Hampshire. Weston has used their unit at sites at Tinker Air Force Base in Oklahoma and Letterkenny Army Depot in Pennsylvania.

The effluent soil would be sampled periodically to ensure that sufficient treatment has occurred. The effluent air would be monitored to assure that the levels of organics do not exceed design criteria. The temperature of the thermal desorption vessel will be monitored to ensure proper treatment.

A summary of ARAR compliance is shown in Table 4-2.

4.3.2.2 Implementability

Thermal desorption is readily implementable. Mobile units are available from Canonie Environmental in Ohio, ReTeC, Inc., in Massachusetts, and Roy F. Weston or ETG Environment, Inc. in Pennsylvania. Bench- or pilot-scale tests can be run to determine optimal operating conditions. Additionally, all of the necessary emissions control units are commonly employed in industry for air pollution controls.

The thermal desorption unit requires routine maintenance, but this is generally provided by the vendor. The earthmoving equipment also requires routine maintenance.

Mobilization time for thermal desorption is in the range of 1 to 2 months, covering setup time, site preparation, and testing. Treatment time is in the range of 2 to 4 months for approximately 14,500 cubic yards of soil.

4.3.2.3 Cost

The cost of thermal desorption is less than incineration. Treatment cost estimates obtained from vendors ranged from \$215 to \$250 per cubic yard, based upon the understanding of existing site conditions. The total treatment cost for 14,500 yards of soil would be expected to be approximately \$3,500,000. Once the soil is backfilled, there should be no long-term maintenance costs. Costs will be higher if off-site disposal of the treated soil and debris, solidification/stabilization of soils prior to on-site disposal, or extensive testing is necessary. The costs associated with thermal desorption would include the following:

- development of Work Plans and Health and Safety Plans
- obtaining all the necessary permits
- development of sampling and analysis plans
- mobilization
- site development
- soils removal
- segregation operations
- sizing operations
- groundwater treatment (from excavation and dewatering operations)
- thermal desorption
- debris treatment and off-site disposal
- off gas treatment
- water treatment
- water discharge (to creek)
- backfill operations
- site restoration
- ambient air monitoring
- soil and water sampling and analysis
- decontamination of all treatment equipment
- the safe disposal of all secondary wastes generated as a result of the treatment operations such as spent resins, carbon, etc.
- demobilization

These costs do not include oversight costs or contingency costs.

May, 1994

Page 4-23

K:\Seneca\EECA\Section.4

4.3.3 Incineration

Incineration is a technique which uses high-temperature oxidation to destroy a waste. Incineration is effective for a wide variety of organic wastes, even those resistant to biodegradation. During the process, organic materials are generally reduced to CO₂ and H₂O. Residuals from the process may include SO₂, NO_x, HCl, and ash. Any metals in the soil generally end up in the ash. Emissions control devices are effective in minimizing the emissions of these oxidation products.

There are two ways incinerators may be used for a site remediation. Portable units may be brought to a site so contaminated soils may be placed directly into the incinerator. For this site, portable units were considered to meet the objective of onsite treatment.

Three types of incinerators can be used to treat contaminated soils: rotary kiln, fluidized bed and infrared thermal treatment.

Several operational parameters are important in understanding incineration: temperature, residence time, and mixing. The temperature must be high enough to destroy the organic contaminants present in the soil. Residence time is important because the material must remain in the incinerator long enough to be destroyed. The last important operational parameter is mixing. The incinerator must be designed such that the materials are fully dispersed in order to maximize the treatment efficiency.

Rotary-kiln incinerators are often used to treat contaminated soils. They are specifically designed to handle solid materials. The range of combustion temperatures is 1,500 °F to 3,000 °F, with varying residence times depending on this soil and contaminant characteristics.

Fluidized-bed incinerators are used primarily for liquid and slurry wastes, but can be designed to handle soils and other solid materials. Fluidized-bed incinerators are designed to provide better mixing and thus achieve efficient treatment at lower temperatures than rotary-kiln units.

Infrared thermal treatment is somewhat different from the incineration technologies. In this system, the soil is conveyed through an infrared chamber, where it is subjected to infrared radiation at a temperature of approximately 1,400 °F. The combustion products then flow to a secondary chamber, which may be either an infrared unit or a standard incineration unit. The temperature of the secondary chamber is approximately 1,600 °F. The residence time in an infrared unit is generally in the range of 5 to 50 minutes (EPA, 1988a).

4.3.3.2 Effectiveness

Incineration can be extremely effective in destroying of organic contaminants such as TCE, DCE, and the PAHs present in soils in the bend in the road area. Destruction and removal efficiencies of 99.99 percent and 99.9999 percent have been documented (EPA, 1988b). Incineration is not as effective for metals. Metals generally remain in the ash, but may be released to the offgas as particulates or volatiles. Control technologies must be implemented for the metals released to the offgas.

The two major effluents from incineration are the soil-ash mixture and the air stream. Other effluents are baghouse dust from particulate emissions control equipment and any liquid streams from scrubbers used as emissions control equipment. The soil-ash and other solid material must be analyzed and, if necessary, disposed of in an appropriate facility such as a permitted landfill or the materials must be solidified/stabilized for on-site disposal. It may be possible to backfill the soil and solid materials if testing indicates that these materials are not hazardous. Liquid effluent may be able to go to the local POTW or Kendaia Creek after treatment.

Incineration reduces the potential threat to human health and the environment by destroying the organic contaminants in the soil. Metal contaminants remain in the ash and the baghouse dust and must be properly disposed of. Additional treatment of the metals may be necessary prior to disposal.

The major routes of exposure during treatment are direct contact with the contaminated soil and inhalation of vapors or particulates. Protection from exposure can be accomplished through site access controls and the use of proper protective equipment for site workers, such as respirators and Tyvek protective clothing. Air emissions control equipment is used to minimize the threat from airborne contaminants. Air monitoring is often used to ensure that there is no significant threat from the inhalation of vapors or particulates. A summary of ARAR compliance is shown in Table 4-2.

4.3.3.3 **Implementability**

Incineration has been used for a number of years to treat a variety of hazardous wastes.

The startup period for on-site incineration is several months. Time is required to transport the equipment to the site. Testing and trial burns with the site soil are necessary to determine the optimal operating parameters for the site. The regulatory requirements for incinerators are often more stringent than for other technologies because of the air emissions.

The capacity of most mobile incinerators is 2 to 5 tons per hour. Since a cubic yard of soil weighs about 1 to 2 tons, incineration capacity is 1 to 3 cubic yards per hour. Therefore, the treatment time for the Potential Removal Action is in the range of 30 to 60 months if operated 24 hours a day. In addition, the regulations and guidance documents which pertain to hazardous waste incinerated are currently under intense review by the new administration. It is unclear at this time how this would affect the permitting process for a hazardous waste incinerator at a CERCLA site.

4.3.3.4 Cost

The bend in the road area would be considered a small site (EPA, 1988b). Incineration costs for this size site were estimated to be \$1,000 to \$1,500 per ton or \$1,000 to \$3,000 per cubic yard, which covers treatment, mobilization, demobilization, ash disposal, and other incidental costs. Actual treatment costs are only a small part of the total. Costs for mobilization and demobilization are estimated to be over \$1,000,000. Treatment costs are estimated at \$200 per cubic yard. For 14,500 cubic yards, the treatment cost would be at a minimum \$15,000,000. When other costs, such as those for permitting and site preparation, are added, the total treatment cost could be much higher. These costs are anticipated to be almost entirely capital costs. If it is necessary to landfill the residuals off-site, this will likely cost more than \$200 per cubic yard to cover both landfill and transportation costs. Long-term costs should be minimal. Once the residuals are backfilled or landfilled, there will be no continuing costs.

4.3.4 Offsite Disposal

Offsite disposal was the last option evaluated in detail for this removal action. This technology consists of excavating the contaminated areas, segregating the different materials present (soil, debris, water, etc.), and disposing of each media off-site in an appropriate disposal facility. The contaminated media on-site are not a RCRA listed waste, but may be considered a characteristic hazardous waste. Each media would have to be tested prior to treatment and disposal.

4.3.4.1 Effectiveness

Off-site disposal is obviously very effective in removing the contamination from the site, since the soil will be removed. There are potential limits to the effectiveness. During the removal, many of the volatile contaminants will become mobile, and may spread to previously uncontaminated areas of the site, or migrate off-site. In addition, depending on the nature of the off-site disposal option chosen, the material may be simply moved to a landfill, and not permanently remedied. While this will reduce the threat at the site, it will not do away with the long-term threat from these contaminants. A summary of ARAR compliance is shown in Table 4-2.

4.4.3.2 **Implementability**

Off-site disposal is readily implementable at the SEAD Ash Landfill. A number of contractors are available who are very experienced in removing and transporting contaminated material. There is sufficient disposal capacity for this material at a number of treatment and disposal facilities. The equipment necessary for removal and transport is primarily standard earth moving and construction equipment and is readily available from a number of locations if not already owned by the contractor.

4.4.3.3 Cost

The cost of off-site disposal obtained from vendors based upon the current understanding of existing site conditions ranged, from \$4,900,000to \$7,100,000. Mobilization would be expected to take less than 1 month. The entire project including restoration would take an additional 2 to 3 months. The costs associated with off-site disposal include the following:

- development of Work Plans and Health and Safety Plans
- obtaining all the necessary permits
- development of sampling and analysis plans
- mobilization
- site development
- soils removal
- segregation operations
- sizing operations

• groundwater treatment (from excavation and dewatering operations if required)

- debris treatment
- transportation
- offsite disposal
- water discharge (to creek)
- backfill with clean soil operations
- site restoration
- ambient air monitoring
- soil and water sampling and analysis
- decontamination of all treatment equipment
- the safe disposal of all secondary wastes generated as a result of the treatment operations such as spent carbon
- demobilization

4.5 COMPARATIVE ANALYSIS

There are a number of advantages and disadvantages to each technology which were considered in detail in order to select the appropriate remedial technology. These advantages and disadvantages are summarized in Table 4-3.

Two of the technologies, offsite disposal and incineration were eliminated quickly from consideration. Incineration is very effective for treating soils contaminated with organics, but has several major drawbacks. First, it is far more expensive than any of the other options. Incineration is estimated to cost upwards of \$15 million, or approximately \$10 million more than any of the other options. There is also an increased regulatory burden associated with incineration. Even though an air permit would not be required for the incinerator, it would still be necessary to meet all the substantive requirements of the air permit process. This process could add significantly to the time and cost of incineration.

Offsite disposal also was eliminated at the beginning of the decision process. While offsite disposal is very effective in dealing with the site contamination, it is not a treatment option. The contaminated soil is simply moved to another location, in this case, a hazardous waste landfill. It is a goal of this removal action to treat the contaminated soil, and not just use a disposal option.

May, 1994 Page 4-28

TABLE 4-3
REMOVAL TECHNOLOGY COMPARISON

TECHNOLOGY	EFFECTIVENESS	IMPLEMENTABILITY	COST (\$X10°)	ADVANTAGES	DISADVANTAGES
Soil Vapor Extraction	Demonstrated to be effective for volatile organics removal	Highly implementable	2.5	 Lowest Cost Minimum Fugitive Emissions In-situ, no excavation required 	More uncertain in documenting remedial objectives Length of treatment required is 1.5 to 2 years
Thermal Desorption	Demonstrated to be effective for volatile organics removal	Highly implementable	3.5	 Fairly short schedule Outcome is well documented 	 Excavation required, increasing air emissions Higher cost
Incineration	Very effective at destruction of all organics	May be difficult to implement	15.0	• >99.99% destruction of all organics	Highest cost Ash may be toxic
Off-Site Disposal	Effective for removing the source of contamination	Highly implementable	7.1	Short schedule Completely removes source	 Higher cost Excavation required Not a permanent solution

The two remaining options, SVE and thermal desorption were compared in greater detail. Each of these two options has some strong advantages, but also some disadvantages. The primary advantages to SVE are the low cost, ready implementability, and the ability to conduct the remediation in situ. The primary disadvantages are the long treatment time due to the nature of the soils at the site and the uncertainty that the remedial goals have been attained. A preliminary analysis of the effectiveness of the SVE suggests that it may take approximately 18 months to remediate the site, however this may increase to 2 years, if factors such as frozen ground or flooding conditions prevent effective removal rates. The cost would be expected to increase if the remediation time is extended. Another disadvantage is that SVE that it is not effective in removing the PAHs and other semivolatile organics present at the site.

The primary advantages of thermal desorption are effectiveness for organics, and certainty of treatment. The treatment time required for thermal desorption is far more certain than for SVE, and will likely be in the 3 to 6 month range. Depending of the treatment temperature used for extraction, thermal desorption is effective for treating the small quantities of PAHs and other semivolatile compounds present in the soils. While treating the semivolatile organics is not the primary goal of this removal action, removal of these compounds will further protect human health and the environment, and will minimize the potential requirement for future remedial actions. However, there are also disadvantages to thermal desorption. First, it will likely be more expensive than SVE. Secondly, there are more effluents from the system, including the treated soil, air, and water. In addition, any large sized debris removed during the excavation activities will need to be segregated, cleaned, and sent off-site to an appropriate landfill. It is anticipated that the debris will be able to be sent to a nonhazardous waste landfill.

After weighing all of the different options, thermal desorption has been selected as the technology of choice for this removal action. A full discussion of the rationale for selecting thermal desorption, along with a conceptual design is presented in Section 5 of this report.

May, 1994 Page 4-30

5.0 RECOMMENDATION AND ANTICIPATED SCHEDULE

5.1 RECOMMENDATION

The remedial technology recommended for treatment of the soils containing organics at the Ash Landfill is thermal desorption. Thermal desorption, in coordination with air and water treatment units will be very effective in remediating the organic contamination present at the site. The bulk of the contaminated water generated during the removal action will come from the dewatering activities. It is proposed that this water will be collected in a holding tank, and then passed through a treatment train consisting of a multimedia filter followed by an air stripper. If necessary, ion exchange resins could also be used to control metals in the water. The offgas from the air stripper would be treated with either activated carbon or a catalytic or thermal exidation unit.

The air emissions from the thermal desorber will also need to be treated. Several options for treating the off-gas are avaliable. For example, the effluent solvent ladden air may first pass through a condenser, which will separate the air and water. The water will be either reused in the process, or commingled with the dewatered groundwater for additional treatment. Depending upon the moisture content in the air and the concentration of the organics in the air could by-pass the condenser and pass through an organic treatment unit, either activated carbon or a thermal oxidizer. The exact configuration of the thermal desorption unit will vary from vendor to vendor, and may not exactly fit the description proposed here, but the final results will meet all the requirements described in Section 3.

Sizing and debris washing unit operations will also be required. Debris too large to pass through the thermal desorption unit will be segregated, washed, and shipped off-site to an appropriate landfill. Wastewater generated from the debris washing operations will be subject to the same or similar treatment as the dewatered groundwater.

5.2 CONCEPTUAL DESIGN

The removal action will include several unit operations, along with peripheral and support items. This section provides an overview of the proposed removal action, along with a discussion of several important issues. This section is not meant to be a detailed design. Each vendor has a slightly different unit for accomplishing the removal action. Control over the removal action will be accomplished with a set of performance specifications, which will cover everything from mobilization to treatment performance to site restoration. These

May, 1994 Page 5-1

specifications will be developed and issued as part of a bid package, which will be completed once the proposed removal action has been approved.

5.2.1 Site-Specific Work Plans

The first step in the removal action will be developing site specific work, health and safety, and sampling and analysis plans. The work plan will address the steps necessary to complete the remediation, and will include, at a minimum, the following items:

- Mobilization
- Site preparation
- Site layout
- Dewatering trench design and construction plan
- Groundwater removal and treatment
- Excavation plan
- Emissions control techniques
- Stockpiling and segregation plans
- Thermal desorption unit specifications
- System proveout plan
- Site restoration plan

A site-specific health and safety plan will also be developed. Since this is a hazardous waste site, the plan, to be developed by the contractor, will be prepared in compliance with all applicable OSHA regulations. A requirement of the bid package will be that the contractor be in full compliance with all OSHA regulations, including proper training and medical monitoring programs. This plan will address air monitoring which will be conducted as part of the health and safety program.

The last plan to be developed will be a site-specific sampling and analysis plan. Included within the sampling and analysis plan will be a QA/QC plan. The sampling and analysis plan will address several specific areas. First, soil samples will be collected from the extents of the excavation. These samples will ensure that no soils remaining in the ground, and therefore not treated, exceed the NYSDEC soil treatment standards. A statistical approach will be developed to determine the number and location of the soil samples to be collected.

The next item to be considered in the sampling and analysis plan is post-treatment sampling. Both soil and groundwater will need to be sampled after treatment to ensure that all the

Page 5-2 May, 1994

FINAL EE/CA SENECA ASH LANDFILL

treatment criteria have been met prior to discharging the groundwater and backfilling the soil. Again, a statistical approach will be developed to determine the number and type of samples to be collected.

An important part of the sampling and analysis plan is the QA/QC plan. The QA/QC plan will describe the procedures to be followed to ensure that the data collected is valid, and will be accepted as evidence of a successful removal action. At a minimum, the OA/OC plan will address sampling procedures, analytical procedures, data validation and reduction procedures, and quality assurance samples (duplicates, blanks, etc.). The analytical methods specified will be acceptable to NYSDEC and EPA, and will have detection limits low enough to ensure that the treatment criteria have been met.

5.2.2 Mobilization and Site Preparation

Once the work plans have been approved, site preparation and mobilization will begin. The contractor will bring all the necessary equipment to the site, arrange for all required utilities, and obtain all necessary permits. If necessary, pads will be constructed for the equipment, and run on and run off controls will be constructed.

The next step in the site preparation will be installation of sheet piling. Sheet piling will be constructed to hydraulically isolate the areas to be remediated, with room left to drive heavy equipment betweent the treatment area and the excavation.

Sheet piling will be installed 1 to 2 feet into the shale bedrock. If necessary, tie-backs or rakes will be used to provide additional stability. The results of the test pitting at the site indicate that sheet piling is feasible, however, other construction techniques may be used if sheet piling is impractical. Groundwater inflow may be controlled by trench dewatering or with a sump pump within the excavation. Any groundwater collected will be shipped off-site for treatment and disposal in accordance with all state and federal regulations.

Alternate techniques may also be used to provide excavation stability. The sides of the excavation may be sloped to the levels required by OSHA. Shoring or bracing may also be used.

Page 5-3 May, 1994

5.2.3 Excavation

The areas to be excavated are highlighted in Figure 5-1. Excavation of materials will be limited to daylight hours. The rate of excavation will greatly exceed the material sizing and thermal desorption processing rate in order to maintain a sufficient stockpile of treatable material. The area to be excavated will be dewatered prior to the excavation, but if necessary, a pump will be used to remove water from the pit. This water will be pumped into the dewatering trenches, where it will be treated along with the remainder of the water. In order to minimize emissions, dust control foams and other housekeeping measures may be used in the area with the highest concentrations of TCE and DCE, the area adjacent to the bend in the road. The sides of the excavation will be sloped such that shoring will not be required for entry into the pit. The total depth of the excavation will be approximately 8 feet, which is the average depth to the competent shale at the site.

5.2.4 <u>Material Sizing and Debris Washing Operations</u>

Once the material is excavated, it will need to be sized prior to thermal desorption. A staging area will be set up for the stockpiled soil, which will include sizing and debris washing unit operations. Since a portion of the area to be excavated is in the old landfill, there is a potential for varied debris to be present, and material sizing will be important. Debris too large to pass through the thermal desorption unit will be segregated, washed, and shipped offsite to an appropriate landfill. It is believed that this material can go to a nonhazardous waste landfill. Water from the debris washing operations will be collected, and either reused in the process, or treated in a manner similar to the site groundwater.

5.2.5 Thermal Desorption

The heart of the proposed treatment process is the thermal desorption unit. As discussed above, each contractor has a unit with slightly different specifications, and this discussion is only meant to provide an overview of the process, not a detailed design.

First, the material is sized for the unit, and stockpiled. The sized material is then fed to the unit on a conveyor. Some units use a weigher in the conveyor to record the weight of material entering the unit. The material in the unit is then heated, either directly with a flame, or indirectly with heated augers. The material is only heated to a sufficient

May, 1994 Page 5-4

temperature to induce volatilization of the organics, and not to temperatures sufficient for combustion. For this site a higher temperature, in the range of 400° to 600° F will be necessary to ensure removal of the target volatile organics and the semivolatile organics present in the soil.

After the material has passed through the unit, it will be discharged to a "treated material" stockpile where it will be allowed to cool prior to post-treatment sampling. Once the material passes the site specific QA/QC requirements, it will be stockpiled in a "clean material stockpile" and then backfilled in the excavation. Materials which do not pass the testing will be reprocessed.

The air driven off from the soil will contain the organic constituents, and will pass through several treatment units. First, the air will be passed through a condenser, where the water will be removed. This water may be reused in the process, or treated to the SPDES discharge requirements, and discharged to Kendaia Creek. If the work is done in the summer when the water table is low, the water will likely be shipped off-site to a permitted TSD facility rather than treated on-site. The air will next pass through an organic treatment unit, which could be either activated carbon or a thermal or catalytic oxidizer. The treated air will then be discharged. The unit operations for air treatment will be specified so as to ensure that the air leaving the unit meets all of the air ARARs described in Section 3.

5.2.6 Backfill, Site Restoration, and Demobilization

Once sufficient stock of treated soil has been accumulated, backfill operations will begin. The excavated areas will be filled and restored to the original grade. Clean fill will be brought in as necessary to make up for the debris sent offsite and any volume reduction due to processing. The area will then be reseeded with native vegetation. The contractor will be responsible for maintaining the area for enough time for this vegetation to become established. The dewatering system will be removed, and the trenches backfilled with clean fill. At the discretion of the Army, the dewatering system may be left in place once the soil treatment has been completed if groundwater collected in the system still contains organic constituents.

The contractor will also ensure that LDR standards are met. As described earlier, the LDRs for D008 (lead) and D040 (TCE) are ARARs. The LDR for D040 wastes will be met, since

May, 1994 Page 5-6

soils containing a total concentration of 0.7 mg/kg (the TCE TAGM) would have a maximum TC concentration of 0.035 mg/L of TCE. The soils treated during the proveout period will be tested for TCLP lead to ensure compliance with the D008 LDR standard. Soils used for the proveout period will be collected in the vicinity of B-31 to ensure worst case lead concentrations are used.

All of the equipment used by the contractor will be decontaminated prior to leaving the site. Decontamination water will be collected and properly treated and/or disposed of.

5.2.7 <u>Air Monitoring</u>

There are two major sources of air emissions, the excavation and sizing activities and the thermal desorption unit. These two are very different, and merit separate discussions. The program will be designed to ensure compliance with all air ARARs, including the NYSDEC Community Air Monitoring Plan, which specifies action levels at a distance of 200 feet from the removal action, and at the nearest residence. An monitoring station be established at a distance of 200 feet from the operations. If the level of organics in the air reaches 5 ppm at the monitroing station, then monitoring must be conducted at the nearest residence. For this removal action, the depot fenceline will be used instead of the nearest residence, since this is much closer to the operations, and will therefore be more protective of the community. If unacceptable concentrations of target organics are detected at the fenceline, work will be shut down until this situation has been investigation and further controls are implemented to prevent the reoccurrence of this condition.

During excavation and sizing operations there will be emissions from the soil as it is agitated. In order to evaluate the impacts of these activities, the air emissions were modelled. Air emissions from the soil were estimated using the EPA model LAND7 and the 95th percentile upper confidence limit soil concentrations from the soil samples collected within the boundaries of the proposed removal action. The emission rates were then input into the EPA SCREEN model, which estimates the concentration at various downwind receptors. The air modelling data and results are presented in Appendix C. The model showed that even without any control measures, the concentration of organics at the 200-foot monitoring station would always be well below 5 ppm, and that the concentration at the depot fenceline and at the nearest residence would remain well below the NYSDEC annual guideline concentrations (AGCs) and short-term guideline concentrations (SGCs). The AGCs were calculated

Page 5-7

assuming that the unit would be in operation for an entire year, which is a conservative assumption, since the removal action should only last 3 to 4 months.

To further evaluate the air emissions, the SCREEN model was rerun using input values 10 times greater than estimated by LAND7. Again, all of the output values were well bellow their respective criteria. This indicates that emission controls during excavation and sizing will not be necessary to protect human health and the environment and to comply with the ARARs. However, in order to provide more control, the excavation rate will be minimized in the areas showing the highest concentrations of organics, and foams may be used during the excavation. If the excavation is conducted during the winter months, these additional controls may not be used.

Emissions from the thermal desorption units were also modeled with EPA SCREEN and are also presented in Appendix C. Unit specifications from several vendors were used. For the organic emission rate, the input rate of the organics as estimated from the soil concentrations were used. This assumes no emisson controls for organics, a worst-case assumption, since carbon or an oxidizer will be used on the unit.

The results indicate that for the Weston unit, TCE and vinyl chloride, may exceed the AGC value. However, the Canonie unit did not exceed any NYSDEC air guidance values. This is due to the larger amounts of air discharged by the Canonie unit because it is a direct heating type of treatment unit. The Weston unit is an indirect heating unit and therefore does not discharge large amounts of air. Regardless, it is anticipated that treatment of the off-gas (either thermal or catalytic oxidation) will be utilized to protect against any unforseen discharges of potential air pollutants.

5.2.8 Site Health and Safety

The contractor will be responsible for complete compliance with all OSHA and EPA regulations for operations at hazardous waste sites. All workers will have received the mandatory training, and be part of a medical monitoring program. The contractor will prepare and follow a site-specific health and safety plan which will be approved by the Army prior to the start of work. Due to the presence of vinyl chloride at the site, there is a strong possiblity that level B protective equipemnt will be required for portions of the work. When level B activities are conducted, the contractor will set up an exclusion zone, and not allow

May, 1994 Page 5-8

anyone inside the work area who is not in level B equipment. The health and safety plan will contain procedures for dealing with site visitors, including those visitors who have not received proper training. People not receiving proper training may be allowed on site, but will not be allowed in the work area.

5.2.9 Oversight

A third party contractor will be hired to provide oversight for the removal action activities. This contractor willprepare a construction quality assurance (COA) plan which will document the procedures to be followed to ensure that the removal action meets the established specifications. CQA duties will include, but not be limited to the following acitivities:

- Confirmation sampling and analysis from the excavation, treated soil, and treated water
- Air monitoring
- Monitoring of the thermal desorption unit operating parameters

It is anticipated that an oversight conractor will be onsite for the duration of the removal action.

5.3 PROPOSED SCHEDULE

The overall project schedule is shown in Figure 5-2. The total duration for the removal action after regulatory approval is 8 months.

5.4 ESTIMATED COST

The estimated cost of \$3,500,000 is based upon a preliminary estimate provided by Canonie and Weston. A more detailed cost estimate will be prepared in accordance with details and format of the Hunstville Division Design Manual for Architect Engineers.

6.0 PUBLIC COMMENT

According to the NCP (section 300.415 [m][4]), where a removal action is appropriate at a site and where a planning period of at least 6 months exists prior to initiation of site activities, the lead agency (i.e., the Army) must publish a notice of availability and a brief description of the EE/CA. The public will then have an opportunity for not less than 30 calendar days to submit written and oral comments on the EE/CA to the Army. A public meeting could be held, if requested. The NCP also states that a written response to significant comments must be produced after the public comment period (i.e., the responsiveness summary and the action memorandum). Once the action memorandum and the responsiveness summary have been prepared, the removal action is initiated.

1.1.1.1. From Soil Surface

ref. is Mackay & Matsugu 1973

description	description units			value	allowed range	typical value
< Output	>>	=:====	===:			
mass flux per unit area	(moles/m ² -hr)	Q/Ac	=	1.02E-04	= 1.7	7 210-1 9/2-5
< Input Variable		*:====				
windspeed	m/hr	U	=	16092		
pool diameter or diameter of waste boundary	m	Dр	=	1		
Schmidt gas number	_	Sc	=	1.33		
vapor press of the vol at the surface	atm	P	=	0.0001		
pool temperature or temp of waste surface	°K	Тp	=	293		293°K
dist from soil surface down to surface of waste at time 0	m	ho	=	0		0 at surface
Henry's law constant	m³-atm/mol	\mathbf{H}	=	0.086		
length of time waste at present location	hr	·t	=	1		
air diffusion coeff of contaminant	m²/hr	Do	=	0.0382		
soil type constant	-	gamma			.8 ■ gamma ■	
total porosity		epsln_t		0.45 0	mepsln_t m 1	l
air filled porosity	-	epsln_a	=	0.4		
soil type constant	_	μ	=	2.6		
< Intermediates			->>			
vapor phase mass transfer coeff into air	m/hr	ka	=	46.08		
vapor phase mass transfer coeff through soil	m/hr	ks	=	2.46E-02		
effective diffusion coeff of contaminant	m²/hr	De	=	0.00		
dist from soil surface down to surface of waste at time t	m	h	=	0.18		
overall mass transfer coeff	m/hr	k	=	0.024550734261		
< Constants			====			, ,
vapor press of the vol in the atmosphere gas constant	atm atm-m³/mole-°K	P_inf R	=	0 8.21E-05

STATUS CHECK

Waste loading (g oil/cc soil) is relatively large. Time between applications (days) is relatively large.

15/45

CALCULATED VALUES FROM SPECIFICATIONS

SOURCE: land treatment

The area for waste application is 100 m2 (0 acres).

The waste application volume is 28 m3 (7500 gallons).

The tilling depth is 30.0 cm.(11.8 inches).

Attention:

Mr. Michael Curry

Project Engineer

Subject:

Order-of-Magnitude Cost Estimate for Soil Treatment

Dear Mike:

As we discussed, Roy F. Weston, Inc. (WESTON.) would apply its Low Temperature Thermal Treatment (LT.) System to the TCE and DCE contaminated soil on your site. The LT is an indirectly heated screw conveyor to evaporate and condense organics or collect them on carbon columns that would be regenerated at off-site locations. A set of brochures describing the LT are attached.

Because WESTON uses indirect heating the total volume of gas emission is very small. The estimated emission from our processor while treating 20 tph is only 1,400 acfm at 70°F. The 8 inch diameter stack height is adjustable but typically only 6 feet above grade.

The budgetary cost estimate $(\pm 30\%)$ based on the technical date in your 11 June 1993 letter is as follows:

•	Plans and Per-operational Permitting	\$ 355,000
•	Mobilization	\$ 760,000
•	Excavation and Feed Material Prepared (14,500 yd³) (\$20/yd)	\$ 290,000
•	Treatment of Soil (21,750 tons) (\$70/ton)	\$ <u>1,522,500</u>
		\$2,927,500

Engineering-Science, Inc. Attn: Mr. Michael Curry

-2-

12 October 1993

This cost element does not include soil excavation dewatering or water treatment. These cannot be estimated based upon current information.

If you have any other questions, please call me at (215) 430-7423.

Very truly yours,

ROY F. WESTON, INC.

Thermal Desorption Budgetary Cost Estimate Ash Landfill Removal Action

Dear Mr. Curry:

Canonie Environmental Services Corp. (Canonie) is pleased to submit a preliminary cost estimate for completing the Ash Landfill removal action using Canonie's low temperature thermal aeration (LTTA®) process. This submittal is prepared in response to your June 11, 1993 letter to Canonie and includes a description of the proposed remediation system and a budgetary cost estimate for completing the removal action.

Description of the Proposed Remediation System

Canonie will conduct the remediation using its transportable LTTA® soil processor. LTTA® is a thermal treatment technology developed by Canonie to treat soil containing volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), chlorinated pesticides, and other organic compounds. The system cost-effectively separates these hazardous constituents from excavated soil by heating the soil to a temperature of 300° F to 800° F. Following treatment, the soil may be redeposited on-site without restriction. A detailed description of Canonie's LTTA® soil remediation process is presented in the enclosed booklet.

An important aspect of Canonie's LTTA® soil remediation service is the on-site analysis of treated soil to verify compliance with site cleanup criteria. Compliance is verified and documented in Canonie's on-site analytical laboratory before treated soil is returned to the excavation.

Preliminary Cost Estimate

As requested in your June 11, 1993 letter, Canonie has reviewed the site information which you provided and has prepared a cost estimate for budgetary purposes. The estimated costs are presented below:

Item	Estimated Cost
Fixed Costs: Development of work plans, health and safety plans, and sampling and analysis plans; obtaining necessary permits; site preparation; mobilization; site restoration; disposal of treatment residuals such as spent carbon; and decontamination and demobilization of all excavation/treatment equipment.	\$450,000
Treatment Costs: Soil excavation, segregation, and sizing operations; thermal desorption; off-gas treatment; process water treatment; backfill of treated soil; ambient air monitoring; and soil sampling and analysis (assumes treatment of 21,000 tons of soil).	\$2,280,000
TOTAL ESTIMATED REMEDIATION COST	\$2,730,000

The above estimate does not include costs for two items mentioned in your June 11, 1993 letter. These items are ground water treatment and water discharge. Your letter states that the soil requiring excavation may be unsaturated. In this case, dewatering of the excavation and ground water treatment and discharge will not be necessary. Because scrubber water in the LTTA® processor is treated and recycled for reuse or quenching of soil, there is no process water discharge from the LTTA®. Thus, if dewatering of the excavation is not required, there will be no water discharge to the creek or the publicly owned treatment works (POTW). Please note that Canonie has significant experience in designing, constructing, and operating ground water recovery and treatment systems. If ground water treatment is required, we would be happy to provide these services to you.

Conclusions

Based on the information presented in your June 11, 1993 letter, Canonie's LTTA® process will remediate the Ash Landfill soil impacts in a manner which is verifiable, cost-effective, and environmentally sound.

For your information, I have enclosed an LTTA® demonstration bulletin that was produced by the United States Environmental Protection Agency (EPA) Superfund Innovative Technology Evaluation (SITE) program. We are very proud of the success

that has been documented by the EPA, and are certain that the LTTA® process will serve your purposes as well.

If you have any questions regarding the LTTA® process or the budgetary cost estimate, please do not hesitate to call.

Very truly yours,

Douglas M. Anderson, P.E.

Project Engineer

Mr. Michael Curry Engineering Science, Inc. Prudential Center Boston, MA 02199

Dear Mr. Curry:

Enclosed is the budgetary cost estimate you solicited for the remediation of 15,000 yards of soil by thermal desorption. I have taken our price estimates and indicated the tasks which would be included in our general cost catagories. If you need more breakdown I will take some additional time to generate an itemized list.

I have also enclosed a copy of our Statement of Qualifications for thermal desorption and for subsurface treatment which includes soil venting. If you would like ReTeC to provide the same type of cost estimate for soil venting please contact me and I will have the estimate generated.

ReTeC would be glad to visit your offices and present our capabilities in and answer any questions you have concerning the cost estimate and our technology. Thank you for your consideration.

Sincerely,

Paul N. Rice

RE: Removal Action in Western New York State Terra Vac #42-0072

Dear Michael: 1 & Pitte to Be to the property of

Per your request of June 11, 1993, Terra Vac has prepared this preliminary cost estimate for the removal action in Western New York State. Although we have attempted to be as accurate as possible, please keep in mind that this is a preliminary cost estimate only, based upon very limited site data and a preliminary scope of work.

Site Conditions

The site is in and adjacent to a former ash landfill. The surface of the site is unpaved, and gently rolling.

A 2 to 11 foot thick mantle of dense glacial till covers the shale on site. The till is generally characterized by silt, clay, and fine sand.

Groundwater elevation is highly variable, with complete saturation observed in springtime, and totally unsaturated conditions possibly occurring in late summer. Groundwater flow is thought to be from the north-east to south-west.

Approximately 55,000 square feet of the site is impacted with trichloroethylene (TCE), dichloroethylene (DCE), and other volatile and semivolatile compounds. There are two separate areas of contamination, with Area A being 38,000 square feet, and Area B being 17,000 square feet. The depth of contamination varies between 4 and 10 feet to bedrock.

Given the total volume of impacted soil, (14,500 cubic yards) and the average contaminant concentrations (TCE: 42 ppm; DCE: 8 ppm; other VOCs: 2 ppm), Terra Vac estimates that approximately 2,000 pounds of VOCs exist in the soils.

Vinyl chloride has been identified at the site, at an average concentration of 43 ppb. Terra Vac estimates that there is less than 1-1/2 pounds of vinyl chloride at the site.

No groundwater analytical data was available. For purposes of this proposal, it is assumed that the groundwater is impacted with low to moderate levels of the compounds listed above.

<u>Assumptions</u>

This preliminary cost estimate is based upon the following assumptions:

* Electrical service is available nearby

* Terrain is accessible with an ATV drilling rig

* Soil cuttings will be spread on-site

- * Discharge of water will occur to a nearby creek
- * TCE and DCE are the only two compounds of concern
 * Groundwater transmissivity is low, and total dewatering flow rate will be 50 gpm or less
- * Level B personal protection will be required during intrusive operations

Design Basis

Based upon the preliminary information provided, Terra Vac recommends using Dual Vacuum Extraction to dewater the site and remediate the soils. Dual Vacuum Extraction is the process of simultaneously removing both vapors and groundwater from the same well. By lowering the groundwater table and exposing the previously saturated zone to air flow, the source of continuing groundwater contamination is remediated, thereby remediating the groundwater in conjunction with the soil.

With the fairly low total mass of VOCs, carbon adsorption has been selected for vapor treatment. Vinyl chloride is assumed not to be a problem due to the low total mass, but air modeling should be done to verify this prior to the final selection of a vapor treatment system. Extracted groundwater would be treated using a low-profile aeration unit with carbon polish, and discharged to a nearby stream. Vapors from the aeration unit would be treated through the vapor treatment system.

Given the expected low permeability of the site soils, and the shallow depth of contamination, a ten foot effective radius of influence (ROI) has been assumed. Using this ROI, approximately 120 wells are required for Area A, and approximately 50 for Area B. Terra Vac recommends verifying the ROI before full-scale implementation using a phased installation approach.

With 170 shallow wells, a dual vacuum extraction system capable of treating roughly 2500 SCFM of vapors and 50 gpm of groundwater has been assumed. It is anticipated that the extraction blowers will need to be capable of generating a medium vacuum (12" Hg to 18" Hg).

Given the maximum levels of TCE (540 ppm) and DCE (79 ppm), and the stated cleanup objectives (0.7 ppm, 0.3 ppm, respectively), soil concentration reductions of up to 99.9% will be required. Using the system described above, this will likely take 1-2 years. An operational time of 18 months is used for estimating purposes.

Cost Estimate

Terra Vac presents the following preliminary cost estimate for the tasks outlined in the request dated June 11, 1993:

Tas	k	Cost
1.	Work Plan, H&S Plan, S&A Plan, Permitting, Design, Mobilization	\$100,000
2.	Well Installation	\$85,000
3.	Treatment System Installation	\$500,000
4.	Operations, per month \$30,000 Total Operations, 18 months	\$540,000
5.	Interim and Confirmatory Soil and Water Analysis	\$300,000
6.	Demobilization	\$150,000
TOT.	AL ESTIMATED PROJECT COST	\$1,675,000

Please remember that this is a preliminary cost estimate only. Actual costs will vary depending on the actual scope of work and site conditions encountered. In particular, the actual ROI will greatly impact the drilling costs; and the actual water extraction rate will greatly impact the construction and operations cost.

We look forward to presenting a formal bid to Engineering-

TERRA VAC

Science, Inc. later this year. Please do not hesitate to contact us if you have any questions regarding this estimate.

Sincerely,

David E. Ott, P.E.

ENVIRONMENTAL TECHNOLOGIES

RE: Cost Estimate, Soil Vapor Extraction (SVE), Seneca, NY Site

480 NEPONSET STREET CANTON, MA 02021

Dear Mr. Curry:

617-821-5560 617-821-4967 FAX

In response to your request, Vapex Environmental Technologies, Inc., (VAPEX) has reviewed the information that you provided concerning the site referenced above. The following text discusses the results of our review and presents rough cost estimates for your consideration as you develop plans for the remediation of the site.

4100 QUAKERBRIDGE ROAD LAWRENCEVILLE, NJ 08648 1-800-969-VAPEX

As you are aware, VAPEX has built its approach to the design of remedial systems on a fundamental understanding of the sub-surface processes that govern the effectiveness of the technology. While other companies focus on above-ground hardware, VAPEX believes that only by measuring site-specific physical and chemical parameters, and accounting for these factors in the design process, can a predictable, efficient, and cost-effective system be constructed. VAPEX uses proprietary models as design tools and a wealth of construction and operation experience gained from over 250 remedial projects to plan for and achieve site remediation goals.

In addition, as a subsidiary of Envirogen, Inc., a leader in the development and application of biotechnology for the environmental market, VAPEX is uniquely qualified to evaluate, design and implement biological treatment for remedial Envirogen's facility in Lawrenceville, NJ, includes full laboratory capabilities to conduct treatability studies for the accurate assessment of the potential of bioremediation of contaminated soils and groundwater.

This estimate has been prepared based on a review of the data presented in your letter dated June 11, 1993. The costs presented are a rough estimate presented for planning purposes only. In addition, this estimate has been provided to Engineering-Science as a courtesy to assist in the Feasibility Study phase of this program. In return, VAPEX expects to be offered an opportunity to bid on the SVE pilot testing, design and installation phases of the program at the appropriate times.

In general, it appears that these soils will exhibit somewhat low permeability to air when tested. For this reason, we have based our cost estimate on a conservative estimate of the effective radius of influence of each SVE well.

Mr. Curry Page 2

VAPEX's estimate for the site is as follows:

Area A

VAPEX **ENVIRONMENTAL** TECHNOLOGIES

Area: 38,000 square feet Number of SVE wells: 200, each to a depth of 7 feet

Manifold piping: 5,800 linear feet

\$76,000 to \$125,000 Drilling: Manifold and installation: \$98,000 to \$130,000 Equipment, Buildings & Installation: \$200,000 to \$275,000 \$50,000 System Startup:

Subtotal, Northwestern Source Area: \$424,000 to \$580,000

Area B

Area: 17,000 square feet

Number of SVE wells: 85, each to a depth of 7 feet

Manifold piping: 2500 linear feet

Drilling: \$37,000 to \$64,000 Manifold and installation: \$49,000 to \$75,000 Equipment & Installation: \$50,000 System Startup: \$10,000

Subtotal, Northeastern Source Area: \$146,000 to \$199,000

In-Situ Summary

Mobilization: Area A: Area B: Air Controls System: Water Treatment System:		\$ 50,000 \$424,000 to \$580,000 \$ 146,000 to \$199,000 \$150,000 to \$250,000 \$150,000 to \$250,000
Total		\$920,000 to \$1,329,000
Operation & Maintenance (24 months):	6	\$150,000 to \$300,000

TOTAL ESTIMATED COST: \$1,070,000 to \$1,629,000 VAPEX ENVIRONMENTAL TECHNOLOGIES Once again, it was a pleasure speaking with you again, and I hope that this information is adequate for your needs. If you have any questions regarding this estimate, please feel free to contact me or Mr. Peter Nangeroni, P.E., VAPEX's Vice President of Operations.

We would welcome the opportunity to work for Engineering-Science, Inc., on this program or any others in the future.

Sincerely,

VAPEX ENVIRONMENTAL TECHNOLOGIES, INC.

Scott R. Drew

RE: ROMULUS, NEW YORK, PROJECT SITE

RRS Proposal No. 432387

Dear Mr. Curry:

RUST Remedial Services Inc. (RRS) is pleased to submit to Engineering-Science, Inc. this outline of estimated costs for project remediation activities at your client's site near Romulus, New York. These costs are being provided with the understanding that this is for budgetary purposes only and for your exclusive use with your client. These cost numbers cannot be used for any other purpose except by written permission from RRS.

The scope of work provided by you in a letter dated 15 June 1993 results in the following cost outline:

·	Estimated Cost
Develop Work Plans and Health and Safety Plans for site activities	\$5,000
Obtain necessary permits	\$2,500
Develop Sampling Plans and implement sampling program to include analysis for disposal at CWM (Chemical Waste Management, Inc., Model City, NY)	\$50,000
Site Mobilization of Personnel and Equipment to include site preparation and development	\$175,000
Excavate 14,500 cubic yards of contaminated soil	\$275,000
Ground water treatment and dewatering	\$75,000

Transportation and Disposal \$178*-\$278*/ton for 14,500 cu. yds. at 1.5 tons/cu. vd. or 21,750 tons

*\$3,871,500-\$6,046,500

Backfill to grade - site restoration

\$215,000

Air monitoring

\$150,000

Demobilization

\$65,000

Estimated Total: \$4,884,000-\$7,059,000

*Note: Transportation and Disposal costs are dependent on sample analysis and approval at CWM, Model City, NY. These costs can be significantly reduced based on analytical data and sample evaluation.

To provide a very detailed operation plan and cost analysis it would be necessary to meet with your client and visit the project site to better understand your total scope of the project. Because we have not had this opportunity, the cost numbers provided may not represent the true accuracy necessary to provide advisement to your client.

RRS can provide a variety of capabilities to you and your client with respect to this project. Utilizing one company for all on-site activities in conjunction with providing transportation and disposal will be a cost saving advantage to you and reduce your client's environmental liabilities.

RRS offers a wealth of experience (see attached capabilities) as well as access to the resources of other RUST International Inc. companies, including:

- RUST Environment and Infrastructure (REI) with 80 years of environmental engineering and consulting experience;
- RUST Industrial Services with over 15 years of industrial services (including cleaning, demolition, marine construction and scaffolding) experience;
- RUST Construction Services, with 80 years of large-scale heavy construction experience in fields of energy systems, materials handling, chemical processing, metals, environmental and automation control;
- RUST Engineering, with 80 years of experience in architectural, electrical, control systems, mechanical, piping, structural, and civil engineering; and
- RUST Limited, the company's International Business Unit.

Please review these estimated costs and if questions develop please contact me at 716-754-0328 / 215-245-8100.

All correspondence should be forwarded to the RRS regional office at:

RUST Remedial Services Inc. 3220 Tillman Drive, Suite 200 Bensalem, Pennsylvania 19020

Phone 215-245-8100 FAX 215-245-8116

Thank you for considering RUST Remedial Services Inc. for your client's hazardous waste and remediation requirements.

Sincerely,

RUST Remedial Services Inc.

Arthur Pethybridge Ju

Business Development Manager

RUST REMEDIAL SERVICES INC. CAPABILITIES

- ♦ On-site Innovative Technologies
 - Low-temperature thermal desorption
 - X*TRAXTM thermal organics extractor
 - LT*XTM
 - PY*ROX[™] High-temperature incineration of RCRA and PCB wastes
 - In-situ and ex-situ bioremediation
 - MAG*SEPTM metals removal water treatment system
 - ACT*DE*CONTM actinides removal chemical treatment system
 - Soil vapor extraction
 - Chem*MatrixSM and MEC*ToolTM ex-situ and in-situ stabilization and solidification systems
 - De*ChlorTM chemical dechlorination system
 - Groundwater, surface water, and wastewater treatment
 - PO*WW*ERTM organics separator
 - Pumping and extraction
 - Injection wells
 - Air stripping
 - UV oxidation
 - Modeling
 - Feasibility studies
 - Carbon phase filtration
 - Filter pressing
 - Fuel recovery
 - Chemical neutralization, reduction, and stabilization
 - Oil/water separation
 - Biodegradation/bioreclamation
 - Ion exchange

♦ Engineered controls

- Slurry trench cut-off walls
- Landfill/impoundment closures
- Permeable and impermeable caps
- Subsurface drains
- Grout curtains
- Sheet piling cut-off walls
- Injection barriers and flow control
- Waste site bottom sealing
- Dikes and levees
- Revegetation
- Grading contouring
- ♦ Media monitoring and sampling
- ♦ Air pollution controls
 - Gas collection and venting
 - Dust suppression
 - Wind screens
- ♦ Nuclear waste treatment and disposal
- ♦ Excavation and off-site disposal of contaminated materials

APPENDIX E

COMMENTS\RESPONSE SUMMARY

RESPONSES TO THE EPA COMMENTS - ACTION

3.0 GENERAL OVERVIEW

3.1 Action Memorandum

A removal action appears to be appropriate at this site based on the criteria outlined in 40 CFR 300.415(b)(2)(i) (actual or potential exposure to nearby human populations, animals, or the food chain from hazardous substances or pollutants or contaminants), and 40 CFR 300.415(b)(iv) (high levels of hazardous substances or pollutants or contaminants in soils largely at or near the surface, they may migrate). The removal action also appears to be warranted based on the requirements outlined in 40 CFR 300.415(b)(ii) (actual or potential contamination of drinking water supplies or sensitive ecosystems). It should be noted, however, that the Action Memo does not explicitly state that there is a threat to drinking water supplies; it states only that there is a threat to "groundwater".

While a removal action appears appropriate for this site, the Action Memo does a poor job in presenting the information required to substantiate the need for such action. (According to the Guidance, one of the main objectives of an Action Memo is to substantiate the need for a removal action based on the criteria outlined in the NCP). Additional information regarding the scope and objectives of the removal action, and the extent of site remediation achieved by implementing this action, needs to be provided in the Action Memo to clearly demonstrate the need for this action. (The specific additional information requirements to complete the Action Memo are outlined in the Detailed Technical Evaluation Section of this report (Section 4.1).

3.2 Engineering Evaluation/Cost Analysis

The EE/CA report is, in general, technically sound in terms of selecting a viable technology to achieve the removal action objectives. However, there are several technical issues that should be addressed in further detail in the EE/CA. These issues included:

Comment #1

Potential dense non-aqueous phase liquid (DNAPL) source--TCE concentrations in excess of 11,000 ug/l have been detected in the source area. Concentrations in this range indicate that a free phase source may be present at the site. Since the dewatering activities planned as part of the removal action have the potential to mobilize DNAPL, and since the site exhibits fractured shallow bedrock, the potential exists for "spreading" contamination to the lower aquifer. The Action Memo, therefore, should include information from site investigations that demonstrates that the potential for "spreading" contamination does not exist.

Response #1

Although, the TCE concentrations detected in groundwater from the two wells, MW-44 and PT-18, are in the neighborhood of 1% of TCE solubility (one of the indications of a potential DNAPL source), the historical use of the site does not suggest the existence of a DNAPL source. The type of operations at the site and the waste practices employed do not suggest a high probability of historical DNAPL release. The high concentrations of TCE detected are concentrated in the MW-44 and PT-18 areas. Data collected in

nearby sampling points showed a significant decrease of TCE concentrations. In addition, none of the borings or water samples taken in the "hot spot" contained DNAPLS.

Comment #2

Lack of Performance Criteria for Treatment Equipment--The primary objective of this removal action is to remove the TCE and DCE contamination in the soil, and therefore, eliminate the source of groundwater contamination. However, it is not possible to evaluate the effectiveness of the remedial alternatives in achieving these goals since the EE/CA does not provide specific information regarding the level of contaminant reduction (concentration or mass) expected when using a particular remedial technology, i.e., no performance criteria for treatment equipment is provided. The level of treatment required is an important criteria in system selection/design and cost analysis, and in the evaluation of potential further remedial actions. The target level for TCE and DCE should, therefore, be specified explicitly. The efficiency of each treatment alternative in meeting these target levels should also be addressed.

Response #2

The clean-up objectives have been established which are consistent with 6NYCRR Part 375, "New York Rules for Inactive Hazardous Waste Disposal Sites" and the New York State TAGM dated November 16, 1992. The clean-up objectives are as follows:

TCE - 0.7 mg/kg DCE - 0.3 mg/kg

The treatment equipment performance and efficiency will be specific to the selected vendor. All the specified technologies are capable of meeting these criteria.

Comment #3

Incomplete information to fully evaluate remedial alternatives—The following information should be included in the EE/CA so that each remedial alternative can be fully evaluated:

- preliminary soil and groundwater treatment rate;
- preliminary sizing of equipment;
- treatment levels expected;
- special requirements for control;
- time frame for the removal action.

Response #3

Total volume of soil to be treated is estimated to be 14,500 cubic yard as stated in the report. Dewatering will be minimized by conducting the removal action during dry season and by pumping out any water which may collect in the excavation. A minimum amount of groundwater will be collected, stored and treated offsite. A proposed treatment schedule is shown in Figure 5-2 of EE/CA. Refer to response #2 for treatment levels. Sizing of equipment & treatment controls will be provided by vendor.

4.0 DETAILED TECHNICAL EVALUATION

4.1 Action Memorandum

Section 2.1.3.1- Geology

Comment on

pg. 2-5

Figure(s) representing a cross section of the site stratigraphy should be included in Section 2.1.3 of the Action Memo. The figure(s) should depict both the shallow till/weathered aquifer and the deep competent shale aquifer that are described in Section 2.1.3.2. The figures should also include information regarding the vertical extent of soil contamination as well as depict the depth to groundwater. Such information is needed to fully evaluate the extent of contamination and, therefore, the effectiveness of the proposed technology for the purpose of site remediation. Also, a concise depiction of site contamination would facilitate assessment as to whether the need for a removal action is substantiated by the Action Memo.

Response on

pg. 2-5

Information regarding the site stratigraphy and the vertical extent of soil contamination and the depth of unsaturated zone can be found in the EE/CA and in the RI report.

Section 2.1.4.3- Groundwater Contamination

Comment on pg. 2-16 ¶2

This paragraph implies that isocontours up to a maximum of 10,000 ug/l define the groundwater plume in the shallow till aquifer. Figure 2.5, however, shows an isocontour of 100,000 ug/l. This discrepancy should be reconciled. It should be noted that concentrations in this range (100,000 ug/l) approach the solubility of TCE and, therefore, may indicate the presence of a dense phase non-aqueous liquid (DNAPL) in this area. It is recommended that Section 2.1.4.3 include a discussion of the potential for free phase product at this site.

A figure depicting the vertical extent of contamination should also be included in this Section. Information regarding groundwater contamination is relevant to the evaluation of the effectiveness of the proposed removal action since the area to be remediated is to be dewatered for excavation purposes.

Since dewatering activities have the potential to mobilize DNAPL, and since the site exhibits fractured shallow bedrock, the potential exists for "spreading" contamination to the lower aquifer. The Action Memo, therefore, should include the above mentioned information to allow a determination of the potential for "spreading" contamination. Also, information regarding the level of contamination expected in the extracted groundwater should be included in this section since the groundwater will require treatment to appropriate levels.

Response on pg. 2-16, ¶2

The maximum VOC concentration isocontour of 100,000 ug/l is added to the text following the 10,000 ug/l isocontour. However, the 100,000 ug/l is the total VOC concentration detected in the groundwater, not the TCE concentration. The maximum TCE concentration detected is 37,000 ug/l, which is about 3.4% of TCE solubility. The possibility for TCE presence as a DNAPL source is very small based on the historical use of the site and the level of TCE contamination.

Again, information regarding the vertical extent of contamination can be found in the RI report.

Dewatering will be minimized by conducting the remedial action during the dry season when the groundwater table is much lower. In addition, this removal action is only an interim action. The objective is to remove the source of groundwater contamination. Final remedial action will be taken place later.

Section 3.4 - Justification for Removal Action

Comment on pg. 3-2, ¶3

A more complete reference to the soil "clean-up criteria" established by the State of New York referenced in this paragraph should be given. It is recommended that a list of the clean-up criteria, i.e., concentrations, for the target contaminants be given in Section 3.0 of the Action Memo in order to clearly document the clean-up levels being proposed.

It is also recommended that a comparison of the proposed clean-up levels, i.e., the New York, State "criteria", and the "risk-based" levels likely to be used in the final site remedy for <u>all</u> site chemical of concern be included in Section 3.0.

This information will help determine the "value" or effectiveness of the proposed removal action in achieving the overall site remedial goals. That is, this information will help determine the "permanence" of the proposed remedial action. Such an evaluation is espoused under the Superfund Accelerated Cleanup Model (SACM) for the purpose of making site remediation more timely and efficient. (See OSWER Publication 9203.1-051 for SACM guidance.)

Response on pg. 3-2, ¶3

The requested information can be found in Table 3-2 and Table 3-3 of the EE/CA report.

Comment on pg. 3-2, ¶4

This paragraph states that "the site would still be subjected to further investigatory activities within the CERCLA process to confirm acceptable clean-up...". As stated above, SACM requires that the "permanence" of any

"early action" taken at a site, be evaluated in terms of its value in accelerating the overall site cleanup. It is, therefore, recommended that a summary of the potential future remedial alternatives being considered for this site be included in the Action Memo to help determine the contribution of the proposed action in achieving the overall site goals. This information will help determine to what extent implementation of the proposed action will address the overall human health and environmental threats at the site (e.g., will leaching potential of contaminants be fully/partially eliminated by this action, etc.) Such information would also help evaluate the consistency of the proposed action with the potential future site remedy. This information should be readily available as the Action Memo states that the "RI/FS report is currently in preparation" (p.2.2, ¶2).

Response on pg. 3-2, ¶4

The potential future remedial alternatives for this site will be evaluated in the RI/FS reports and are not a concern of this remedial action. Further site investigation and technology evaluation are needed in achieving overall site remediation.

Section 5.0 - Description of Proposed Action

Comment on

pg. 5-1

The description of the proposed action (Section 5.1.2) does not include information on the following items: depth of excavation, total volume of soil to be removed and treated, total volume (rate) of groundwater to be extracted (for dewatering purposes), and description of the treatment process for the extracted groundwater. This information should be included in the Action Memo so that the scope of the proposed action is clearly defined.

Response on pg. 5-1

An average excavation of 8 feet is proposed in the EE/CA report. The total volume of material excavated is 16,300 cubic yards and the total volume of soil to be treated is estimated to be 14,500 cubic yard and is presented in the EE/CA report. The treatment process is described in the EE/CA report as well. Since the removal action is scheduled for the dry season, the volume of extracted groundwater will be minimal.

Comment on pg. 5-3, ¶2

This paragraph states that "any soil which fails post-treatment sampling will be reprocessed". It is implied that the soil cleanup criteria established by the New York State Department of Environmental Conservation (NYSDEC) referenced in the Action Memo constitute the "failure point". However, it is unclear whether both volatile organic compounds (VOCs) and semi-volatile organic compounds must meet the NYSDEC criteria before the soil is "backfilled". Several areas of the Action Memo suggest that the (only) goal of the removal action is to "remove the source of groundwater contamination" (defined in the Action Memo as VOCs only) and that "other constituents at the site will be addressed in the RI/FS process" (see p. 2-19, ¶2). If both VOCs and semi-VOCs are to meet the NYSDEC criteria, then this should be explicitly stated in the text.

This paragraph also states that "if the treated material passes the post-treatment sampling, it will be backfilled". It should be noted that such actions constitute "placement" of waste inland and, therefore, are subject to land disposal restrictions (LDRs). Since the target contaminants of concern and their (proposed) corresponding clean-up levels are not clearly stated in the Action Memo, it is uncertain if the clean-up levels are consistent with applicable LDR standards. It is recommended that a list of <u>all</u> potential site contaminants, i.e., VOCs, semi-VOCs, metals, etc., in the soil that are subject to LDR standards be listed in the Action Memo to ensure that the proposed technology (thermal desorption) is evaluated in terms of the appropriate level of treatment that needs to be achieved in order to "backfill" the treated residuals as proposed.

Response on pg. 5-3, ¶2

Semi-volatile organic will be tested in the post-treatment sampling, however, only the volatile organic compounds are the major concern of this remedial action and subject to any applicable regulatory requirements.

Since the materials to be excavated are not listed wastes, the only possibility of these materials being classified as a hazardous waste is by application of the toxicity characteristic. Of the TC constituents, only trichloroethene and lead were present in at least one soil sample at a concentration at which the TC levels could potentially be exceeded. Therefore, only the LDR levels for D008 and D040 need be considered.

Section 5.2 - ARARs

Comment on

pg. 5-6, **¶**2

This paragraph states that "SVE" will be used for treatment of soils. This statement should be reconciled with the fact that thermal desorption is the proposed remedy for site soils.

Response on pg. 5-6, ¶2

Agreed. The text is corrected from "SVE for the treatment of soils ..."to "Thermal Desorption to the treatment of soils ...".

Comment on pg. 5-6, ¶3

The Chemical Specific ARARs analysis does not consider LDR requirements. The implication of these requirements for the proposed remedy are outlined in the comment for page 5-3, ¶2, above. The ARARs analysis also does not discuss the regulatory provisions for use of a corrective action management unit (CAMU) as part of site remediation. These provisions (outlined in 40 CFR 268.552) may be applicable to this remedy for the management of the treatment residuals in the event that thermal desorption cannot meet the LDR standards for all site constituents. A discussion of the CAMU regulations should, therefore, be included in this Section of the Action Memo.

Response on

pg. 5-6, ¶3

As mentioned above, the only LDR requirements which potentially apply are those for TCE and lead. LDR requirements apply only for hazardous wastes, not simply because a potentially hazardous constituent is present. A brief discussion of LDR and CAMU will be added to the text.

4.2 - Engineering Evaluation/Cost Analysis

Section 2.2.2 - Regional Hydrogeology

Comment on

pg. 2-7

Information regarding depth to groundwater and the area of water table fluctuation should be included as part of the Regional Hydrogeology Section of the EE/CA.

Response on

pg. 2-7

Refer to Figure 3-25 and Figure 3-26 in the RI report for the requested information.

Section 4.3.1.1- Effectiveness (of Soil Vapor Extraction)

Comment on

pg. 4-7, ¶3

This paragraph states that water separated from the dewatering system associated with the SVE process is to be treated by dual-media filtration followed by air stripping. However, the SVE Blockflow Diagram, Figure 4-1 on p. 4-8, shows activated carbon filters instead of an air stripper. The description should be consistent with the flow diagram.

Response on

pg. 4-7, ¶3

Agreed. The discrepancy will be corrected.

Comment on

pg. 4-7

An analysis of compliance with ARARs and other criteria should summarize which requirements are applicable or relevant and appropriate to the particular alternative and describe how the alternative meets those requirement. This analysis is required by EPA to be included in the treatment technology effectiveness analysis, however, is not found in this section.

Response on

pg. 4-7

A detailed analysis of compliance with ARARs and other criteria is presented in section 3.2 of EE/CA. The selected alternative has to be in compliance with all the listed requirements. Control and monitoring of all the discharge effluents are required to ensure the requirements are met.

Section 4.3.1.3- Cost (of Soil Vapor Extraction)

Comment on pg. 4-9, ¶6

The two areas to be treated are estimated to be 38,000 sf and 17,000 sf, per p. 2-33. The average depth of excavation is stated to be about 8 feet. The total volume of soil to be treated is approximately 16,300 cubic yards based on the above information. However, the cost estimate here is based on 14,500 cubic yards. This discrepancy should be reconciled.

Response on pg. 4-9, ¶6

The total volume of material to be treated is approximately 16,3000 cubic yards. Assuming 10% of this material is debris, the total volume of soil to be treated is estimated to be 14,500 cubic yards. The text will be clarified to reflect this assumption.

Comment on pg. 4-9, ¶7

The cost estimate provided in this section does not provide the level of detail recommended by the EE/CA Guidance. Only a "budgetary" cost estimate is given in the EE/CA report, i.e., a detailed breakdown of all components of the cost estimate is not provided. The following list outlines the items for which no specific cost was given. Also, the items in the list marked with an asterisk are said to be included in the "budgetary" cost estimated given. However, no cost "backup" for these items is supplied in the estimates included in Appendix D of the EE/CA.

- Engineering and design;*
- Permitting costs:*
- Start-up and shakedown costs;
- The development of health and safety plans;*
- The development of sampling and analysis plans;*
- Mobilization and demobilization costs:*
- Site development cost:*
- Site restoration cost;*
- Decontamination operations costs;*
- Disposal of secondary waste cost;*
- Auxiliary material and energy costs.

It should be noted that no costs are included in the estimate for "long-term maintenance" costs. It may be premature to assume that long term monitoring will not be required since it is not known at this time whether the residual contamination level in the soil will be "protective" of human health and the environment. Long-term groundwater monitoring may be required to gauge the effectiveness of the removal action in eliminating the source of groundwater contamination.

Response on pg. 4-9, ¶7

The cost estimations presented in the EE/CA report are for budgetary purpose only. The SVE is not in favor for this removal action. If it is believed that there are additional costs should be added, this alternative will be even more at the non-favorable end. Therefore, it is not necessary at this stage to get into further details in the cost estimation of the SVE system.

Section 4.3.2 - Thermal Desorption

Comment on

pg. 4-10

An analysis of compliance with ARARs and other criteria should summarize which requirements are applicable or relevant and appropriate to the particular alternative and describe how the alternative meets those requirement. This analysis is required by EPA to be included in the treatment technology effectiveness analysis, however, is not found in this section.

Response on pg. 4-10

Refer to the response on pg. 4-7.

Comment on

pg. 4-11

A bag-house or scrubber is recommended her for particulate control, however, this equipment is not shown on the Thermal Desorption Blockflow Diagram, Figure 4-2, p. 4-12. An air stripper is described in the text as part of the groundwater treatment process, however, activated carbon filters are shown on the Blockflow Diagram. The system description should be consistent with the diagram.

Response on

pg. 4-11

Agreed. The blockflow diagram, Figure 4-2, is modified accordingly.

Section 4.3.2.2- Cost (of Thermal Desorption)

Comment on pg. 4-13, ¶6

As per p. 5-4, the average excavation depth of soil is 8 feet and the total area to be treated is about 55,000 sf. Based on this information the total volume of soil to be treated is 16,300 cubic yards. The cost estimate for soil treatment via thermal desorption, however, is based on 14,500 cubic yards of soil. This discrepancy should be reconciled.

The cost estimate provided in this section does not provide the level of detail recommended by the EE/CA Guidance. Only a "budgetary" cost estimate is given in the EE/CA report, i.e., a detailed breakdown of all components of the cost estimate is not provided. The following list outlines the items for which no specific cost was given. Also, the items in the list marked with an asterisk are said to be included in the "budgetary" cost estimate given. However, no cost "backup" for these items is supplied in the estimates included in Appendix D of the EE/CA.

- Engineering and design;
- Start-up and shakedown cost;
- Development of sampling and analysis plans;*
- Site development;*
- Dewatering and groundwater treatment costs;*
- Off-gas treatment cost;*
- Decontamination of all treatment equipment;*
- Operating and Maintenance costs;
- Auxiliary materials and energy costs.

It should be noted that no costs are included in the estimate for "long-term maintenance" costs. It may be premature to assume that long term monitoring will not be required since it is not known at this time whether the residual contamination level in the soil will be "protective" of human health and the environment. Long-term groundwater monitoring may be required to gauge the effectiveness of the removal action in eliminating the source of groundwater contamination.

Response on pg. 4-13, ¶6

Refer to the previous response for p. 4-8, ¶6 for the excavation depth used to estimate the total volume of soil to be treated.

The cost for development of sampling and analysis plans is included in the cost estimation for work plans. Site development is included in Mobilization cost. Costs for dewatering and groundwater treatment and off-gas treatment are included in the Thermal Treatment costs. Decontamination cost is covered in the Work Plan. Long-term monitoring will be considered after the final remedial action is accomplished.

Section 4.3.3.2- Effectiveness (of Incineration)

Comment on

pg. 4-15

An analysis of compliance with ARARs and other criteria should summarize which requirements are applicable or relevant and appropriate to the particular alternative and describe how the alternative meets those requirement. This analysis is required by EPA to be included in the treatment technology effectiveness analysis, however, is not found in this section.

Response on pg. 4-15

Refer to the response for pg. 4-7.

Section 5.2 - Conceptual Design

Comment on

pg. 5-1

In this section, more detailed design information should be provided, such as, treatment rate for soil, groundwater, and air; preliminary sizing of equipment. A preliminary Process Flow Diagram should also be included here.

Response on

pg. 5-1

The treatment system will be a vendor package. Treatment process details and sizing of equipment will be vendor's responsibilities. Process Flow Diagram will be provided by selected vendor as well.

Section 5.2.5 - Thermal Desorption

Comment on

pg. 5-6

Bag-house for particulate control was mentioned in previous sections, however, is not discussed in this section. Information regarding this equipment should be included in this section if it will be part of the thermal desorption system.

Response on

pg. 5-6

Actual equipment to be used in particulate control is up to selected vendor. Bag-house is recommended as one of the alternatives.

Section 5.3 - Proposed Schedule

Comment on

pg. 5-9

This section states that "The total duration for the removal action after regulatory approval is 18 months to two years" which is inconsistent with 8 months duration shown on Figure 5-2. This discrepancy should be reconciled.

Response on

pg. 5-9

Agreed. The total duration for the removal action after approval is changed from "18 months to two years" to "approximately 8 months".

HAZARDOUS WASTE FACILITIES BRANCH

Comment #1

Although remediation at the Seneca Army Depot is being conducted pursuant to a Federal Facility Agreement (FFA), with CERCLA as the lead remedial program, it should be noted in the Action Memorandum Report, and in subsequent reports, that this site is a RCRA treatment and storage facility (TSF) and that the remedial activities being conducted under the FFA are equivalent to and will satisfy RCRA requirements for corrective action.

Therefore, Section 1, Introduction, of this report should specify that this Removal Action also satisfies the requirements of an RCRA Interim Corrective Measures (ICM).

Response #1

Agreed. The recommended text will be added to Section 1.0.

Comment #2

Section 5.1.2-Proposed Action Description: specifies that contaminated soil and debris will be excavated and stockpiled. The stockpiled material will be sized, and material too large to pass through the thermal desorption unit will be segregated. The large material will be washed in a debris washing area.

After being washed, the debris will be sent off-site to an approved non-hazardous waste landfill.

This section should have provisions for the management and proper disposal of the wastewater generated by the debris washing area.

Response #2

Agreed. A brief description of the wastewater management will be included in the text.

Comment #3 Section 5.2.3 - Action Specific ARARs:

The following requirements are applicable if hazardous waste are generated during the removal action and treatment of contaminated soil and debris:

40 CFR Part 261 - Identification and Listing of Hazardous Waste and 40 CFR Part 262 - Standards Applicable to Generators of Hazardous Waste.

Hazardous Waste Management - This section should include 40 CFR Part 268, Land Disposal Restrictions (LDR), as an applicable requirements. Please be aware that EPA has promulgated regulations under the LDR that establish treatment standards for debris contaminated with RCRA listed hazardous waste or debris that exhibits hazardous waste characteristics (see Federal Register Notice dated August 18, 1992).

Transportation of Hazardous Waste - This section should include 40 CFR Section 268.7 of the Land Disposal Restrictions (LDR) as an applicable requirement. Section 268.7 requires that each shipment of hazardous waste be accompanied by a notification. This notification should specify whether the waste is subject to the LDR rules, should include all applicable EPA hazardous waste codes and the treatment standards or prohibition levels that apply.

Response #3

Agreed. These ARARs will be added to Section 5.2.3 of the Action Memorandum.

REMOVAL AND EMERGENCY PREPAREDNESS PROGRAMS

Other than a general discussion of distant municipal wells (e.g., Waterloo, Ovid, Seneca Falls), and general population percentages on groundwater usage locally, the location and proximity of potable wells or irrigation wells near the site are not discussed. This issue should be addressed in the revised document. One map in the Action Memorandum indirectly indicates "farmhouse wells" at an approximate distance of 1,250 feet in a westerly direction from an unknown location on the edge of the site.

The airborne exposure is not supported by the soil gas sampling results. The soil exposure scenario is not realistic for a removal action since it is hedged on potential threats to a potential exposure in the future.

Response:

Agreed. Groundwater usage is described and evaluated in detail in the RI report. The purpose of this Action Memorandum is simply to document that a threat exists, and that there is sufficient justification to conduct the Removal Action. It is also agreed that the airborne exposure scenario is not a realistic current scenario. However, the reason for including this scenario is to further justify the removal action. We believe that the potential for this exposure scenario further justifies conducting the removal action.

AIR PROGRAMS BRANCH

Air emissions estimated were far below their respective criteria for excavation and activities even without any control measures. However, results indicate that emissions of trichloroethylene and vinyl chloride from the thermal desorption unit may exceed criteria levels. Offgases from these units must be treated to reduce emission to safe levels. The attached document "Options for Control of Vinyl Chloride from Superfund Remediation Technologies" should be followed in designing offgas treatment.

Response:

Agreed. As indicated in the Action Memorandum offgas controls will be used. These controls will be designed to treat vinyl chloride.

GENERAL OVERVIEW

Action Memorandum

The majority of the comments have been adequately addressed. Appropriate backup for this removal action is contained in the Action Memorandum (AM) and Engineering Evaluation/Cost Analysis (EE/CA). However, the EE/CA states that the purpose of this removal action is to mitigate the source of Trichloroethene (TCE) and Dichloroethene (DCE), and that other potential constituents of concern identified in the Remedial Investigation (RI), including metals and polynuclear aromatic hydrocarbons (PAHs) are not the focus of this action. Based on the selected remedial action which includes full excavation, it would seem appropriate for the action to address all constituents of concern. If future actions under the RI/FS for metals and PAHs require handling of the soils for a second time does not clearly demonstrate a streamlining. Finally, the AM should present the measures to be undertaken so the that LDR standards are met.

Engineering Evaluation/Cost Analysis

Comment #1 Based on the results of the teleconference, the excavation plan would limit the drawdown of groundwater due to the installation of sheetpiling around the perimeter of the excavation, excavation during low groundwater periods, low inflows of groundwater into the excavation from soils with moderate to low permeability, and minimal construction dewatering (not dewatering of excavated soil prior to treatment). However, substantial difficulties could be expected during sheetpile installation due to dense tills with a significant gravel, cobble and boulder content, weathered bedrock

(shale). Consideration to other methods of excavation support and groundwater should be considered.

Response #1 Agreed. As described, sheet piling is the preferred method for providing excavation support and controlling groundwater flow. Sufficient data was obtained from the test pitting conducted at the Ash Landfill to indicate that sheet piling is feasible. During construction, the contractor may use tie-backs or rakes to support the sheet piling. Other techniques which may be used to control groundwater flow are sump pumps in the excavation, or trench dewatering. Other techniques which may be used to provide excavation support are side-sloping and shoring.

Comment #2 The response is acceptable.

Comment #3 The response is acceptable. Performance criteria will be detailed in performance technical specifications which will be included in the bid package.

DETAILED TECHNICAL EVALUATION

Action Memorandum

Section 2.1.3.1- Geology

pg. 2-5 The response is acceptable.

Section 2.1.4.3- Groundwater Contamination

pg. 2-16 Refer to evaluation of EE/CA comment #1.

Section 3.4 - Justification for Removal Action

pg. 3-2 The response is acceptable.

As previously stated, although this action mitigates the source of groundwater TCE and DCE contamination, it does not address other contaminates of concern. If future actions under the RI/FS for metals and PAHs require excavation in this area, then this action may not accelerate the RI/FS process. If treated materials are not fully characterized for all constituents of concern prior to backfilling, this area may require recharacterization.

It should be noted that the detection limits for many of the semi-volatiles were significantly above the NYSDEC TAGMs (Refer to EE/CA Table 2-5).

Response

Pg. 3-2 Exception. The backfilled materials will be analyzed for semi-volaitle organic compounds, including PAHs prior to backfilling. There is no need to conduct extensive analyses for metals because there have already been over 80 metals analyses conducted within the area of concern. The metals concentrations are not expected to change significantly during the removal action.

It is true that the detection limits for the semi-volatiles were greater than the TAGMs. As described in the TAGM, if the method detection limit is greater than the TAGM, then the TAGM becomes the method detection limit. In addition, it should be noted that semi-volatiles were analyzed by the NYSDEC CLP protocol, which was the methodology required by NYSDEC.

Section 5.2 - ARARs

pg. 5-6 The response is acceptable.

pg. 5-6 This response can not be reviewed until the revised AM is available.

4.2 EE/CA

Section 2.2.2 - Regional Hydrogeology

pg. 2-7 This response is acceptable.

Section 4.3.1.1- Effectiveness

Section 4.3.1.1- Cost

Section 4.3.2 - Thermal Desorption

Section 4.3.2.2- Cost

Section 4.3.3.2- Effectiveness

Section 5.2 - Conceptual Design

Section 5.2.5 - Thermal Desorption

Section 5.3 - Proposed Schedule

These response are acceptable.

Comment #6

The recommended remedial technique for treating soil near the "bend in the road" area of the site by thermal desorption seems appropriate. However, if this treatment is unsuccessful in removing contaminants in soil to acceptable levels, additional remediation will be necessary. Furthermore, it is clear that groundwater remediation is warranted, and other contaminated areas at the Ash Landfill will need to be addressed.

Response #6

Acknowledged. This removal action is an interim remedial action. Any failure of removing contaminants in soil will be taken care by the final remedial action. Groundwater remediation and clean up of other contaminated areas at the Ash Landfill will be address in the RI/FS report.
